Although the greatest care has been bestowed by Regnault, Joule, and all other accurate thermometric experimenters to avoid error from this cause, we have still but little definite information as to its natural history in thermometers of different qualities, of glass, different shapes of bulb, and constructed differently in respect to processes of glass blowing, boiling the mercury, and sealing the stem. We do not even know whether the excess of the atmospheric pressure outside the bulb over the pressure due to mercury and Torricellian vacuum inside is influential sensibly, or to any considerable degree, in producing the gradual initial shrinkage. If it were so we might expect that the effect of heating the thermometer up to 100° or more at any time would be rather to produce an accelerated shrinkage for the time than what it is found to be, which is a return towards the original larger volume, followed by gradual shrinkage from day to day and week to week afterwards. A careful comparison between two thermometers constructed similarly in all respects, except sealing one of them with Torricellian vacuum and the other with air above the mercury, would be an important contribution to knowledge of this subject, interesting not only in respect to thermometry, but also to that very fundamental question of physical science, the imperfect elasticity of solids (see *EXPERIMENT*, § 4).

§ 20. The error of a thermometer due to irregular shrinkages and enlargements of the bulb is clearly the less the greater is the expansion of the thermometric fluid with the given change of temperature. By the investigation of § 30 we can calculate exactly how much the error is for any stated amount of abnormal change of bulk in the bulb. But it is enough at present to remark that for different liquids in the same or in similar bulbs the errors are very nearly in the inverse proportions of the expansions of the liquids. Now (Table III below) in being warmed from 0° to 1° C alcohol expands 6 times as much as mercury, methyl butyrate 7 times, and sulphuric ether $8\frac{1}{2}$ times. Hence if irregular changes of bulk of the bulb leave, as they probably do in practice, an uncertainty of $\frac{1}{10}$ th of a degree in respect to absolute temperature by the best possible mercury in glass thermometers used freely at all temperatures from the lowest up to 100° C, the uncertainty from this cause will be reduced to $\frac{1}{10}$ th of a degree by using alcohol, or $\frac{1}{10}$ th by using methyl butyrate instead of mercury, it may therefore, in a glass thermometer of alcohol or of methyl butyrate, be considered as practically annulled (§ 19) after a few weeks or months have passed, and the first main shrinkage is over.

§ 21. An alcohol-in-glass thermometer is easily made strong enough to bear a temperature of 100° C, as this gives by the pressure of the vapour an internal bursting pressure of not quite an atmosphere and a quarter in excess of the atmospheric pressure outside. The boiling point of methyl butyrate (Table III below) is 102° C, a thermometer of it may therefore be used for temperatures considerably above 100° C, but how much above we cannot tell, as we have not experiments as yet on the pressure of its vapour at temperatures above its boiling point. The pressure of vapour of sulphuric ether (Table VI below) is too great to allow a thermometer of this liquid sealed in glass to be used much above 60° or 70° C, but for low temperatures it makes a very valuable thermometer. It was used in 1850 by W. Thomson in finding by experiment the lowering of the freezing point of water, predicted theoretically (see *THERMODYNAMICS*) by J. Thomson in 1849 (*Trans. R. S. E.*), and gave a sensibility of 128 divisions to 1° C. Glass thermometers with ether, or chloroform (whose expansion is about 4 per cent greater than that of ether), were used by Joule and W. Thomson in experiments on changes of temperature experienced by

bodies moving through air, in one of which the sensibility was as great as 330 scale divisions to the 1° C. All these liquids and many others in the modern chemist's repertory of oils and ethers and alcohols, besides the superior sensibility which they give by their greater expansions, have a great advantage over mercury for some thermometric purposes in their smaller specific gravity. This allows the bulb to be larger, with less liability to break or to give disturbed readings through distortion by the weight of the contained liquid.

§ 22. Liquids which wet the glass have another great advantage over mercury in their smaller capillary attraction (see *CAPILLARY ACTION*, vol. v p. 56), and MARUM (*PHILOSOPHICAL*) and in the constancy of their 180° angle of contact with the glass, instead of the much greater absolute intensity of capillary attraction in the mercury, and its very variable angle of contact, averaging about 48° when the mercury is rising, and about as much as 90° when it is falling. On account of these variations the bulb of the mercury thermometer is subjected to abrupt variations of pressure when the mercury is rising or falling. The greatest and least pressures due to this cause are experienced when the angle of contact is respectively least and greatest, and differ by the pressure due to a vertical column of mercury equal in height to the difference of depressions of mercury in a capillary tube of the same bore as the thermometer stem when the angle of contact is changing from one to the other of the supposed extreme values. Hence the mercury in a thermometer rises and falls by jerks very noticeable in a delicate thermometer when looked at with a lens of moderate magnifying power, or even with the naked eye. Dr. Joule informs us that this defect is much greater in some thermometers than in others, and that he believes it is greatly owing to the tube being left unsealed for too long a time after the introduction of the mercury (by which it is to be presumed something of a film of oxide of mercury is left on the glass to cohere on the surface of the mercury when it sinks as it cools after the sealing of the end). In Joule's own thermometers not the smallest indication has ever been detected of what he calls "this untoward phenomenon, which is calculated to drive an observer mad, if he discovers it towards the close of a series of careful experiments." Their admirable quality in this respect is no doubt due to the great care taken by the maker, Mr. Dancer, under Joule's own instructions, to have the mercury and the interior of the bulb and tube thoroughly clean, and to guard it from exposure to any "matter in the wrong place" until completion of the sealing. But no amount of care could possibly produce a mercury thermometer of moderate dimensions moving otherwise than by jerks of even 60 small divisions, if its stem were of fine enough bore to give anything approaching to two or three hundred divisions to the centigrade degree.

§ 23. One chief objection to the use of alcohol or other volatile liquid for the thermometric substance in ordinary glass thermometers is the liability to distillation of some of the liquid into the stem and head reservoir, unless the glass above the level of the liquid be kept at least as warm as the liquid. On this account a spirit thermometer is not suitable for being plunged into a space warmer than the surrounding atmosphere with the stem simply left to take the temperature to which it comes in the circumstances. But whether for elaborate experimental use, or for the most ordinary thermometric purposes, there is little difficulty in arranging to keep the part of the stem which is above the liquid surface somewhat warmer than at the liquid surface, and this suffices absolutely to prevent the evil of distillation. The only other objection of any grave validity²

² There is one other objection which, though often stated as very grave against the thermometric use of any other liquid than mercury, we do not admit to be so. It is that when the temperature is rapidly un-

¹ *Phil. Trans.* for 1850, p. 525.

against the use of highly expansive liquid instead of mercury is the difficulty of allowing for the expansion of the liquid in the stem, if it is not at the same temperature as the bulb. With the same difference of temperatures in different parts of the instrument, the error on this account is clearly in simple proportion to the expansibility of the liquid, and therefore, the residual error due to want of perfect accuracy in the data for the allowance will, generally speaking, be greater with the more expansive than with the less expansive liquid. But in every case in which the bulb and stem can all conveniently be kept at one temperature, a thermometer having for its thermometric substance some highly expansive oil or alcohol or ether, or other so called organic liquid of perfectly permanent and chemical constitution, cannot but be much more accurate and sensitive than the mercury thermometer, which has hitherto been used almost exclusively in thermometry work of the highest rank. We shall see (§§ 62 and 64-66) that the ultimate standard for thermometry, according to the absolute thermodynamic scale (§ 34), is practically attained by the use of hydrogen or nitrogen gas as the thermometric substance, but that for ordinary use a gas thermometer can scarcely be made as convenient as one in which the thermometric substance is a liquid. For practical thermometry of the most accurate kind it seems that the best plan would be to use as ordinary working standard thermometers having thermometric columns constructed of some chosen "organic" liquid, and graduated according to the absolute thermodynamic scale, by aid of the thermodynamically corrected air thermometer (§ 62) used as ultimate standard of reference. The great convenience of the mercury thermometer in respect to freedom from liability to distillation and smallness of error on account of difference of temperature between the bulb and stem renders it the most convenient for a large variety of scientific and practical purposes in which the most minute accuracy of the most extreme sensibility is not required.

§ 24. Without any thermodynamic reason for preferring air to mercury as thermometric fluid, Regnault preferred it for two very good reasons. (1) Its expansion is 20 times that of mercury and 160 times the cubical expansion of glass, and therefore with air the error due to irregularity in the expansion of the glass is 20 times smaller than with mercury, and small enough to produce no practical deduction from absolute accuracy in thermometry, as he found by elaborate and varied trials. So far as this is concerned, some highly expansive organic liquids would answer nearly as well as air for thermometric fluid, and would have the advantage of giving a thermometer much more easily used. (2) For an ultimate standard of reference air has the advantage over organic liquids generally, that different samples of it taken at different times, or in different parts of the world, and purified of water and carbonic acid by well-known and easily practised processes, are sufficiently uniform to give thermometric results between which the

ing, before becoming stationary, a little of the liquid lags behind the descending free surface, due to the glass, and, sticking down to the glass, must be waited for before the stationary temperature can be correctly read. We believe that if a faintly inverted (or mobile) liquid such as alcohol or ether or butyric acid or oil of nutmeg be used, there will be practically no time lost from this cause, and certainly no accuracy lost when proper care is taken by the observer. The observer must be on his guard against a possibly false reading, through the falling of temperature being momentarily delayed in its effect on the free surface by the trickling down of liquid from the glass above, when the free surface is still above, or, it may be, has gone down to a little below, the true position for the final temperature.

¹ Herein, to wit, accuracy, the unqualified word "air" will be used to denote atmospheric air taken in any part of the world, and deprived of carbonic acid and whatever vapour of water it may have contained, by aid of hydrated lime, or caustic potash, or some other suitably reagent for removing the carbonic acid, or sulphuric, or chloric acid, or phosphoric acid, or for removing the water.

accordance is practically perfect, provided the thermometric plan according to which the different samples are used is the same, or as approximately the same as is easily secured in practice. Two plans for the thermometric use of an naturally present themselves—(I) augmentation of volume of air kept in constant pressure, and (II) augmentation of pressure of air kept in constant volume. Regnault¹ tried both plans, but found that he could only arrange his apparatus to give good results by the second, and on it therefore he founded what he called his "normal air thermometer." For the sake of perfect definiteness he chose, as the density of the air in his normal thermometer, the density which air has when at the temperature of melting ice and under the pressure of one atmosphere. He adopted the centigrade scale in respect to the marking of the freezing and boiling points by 0° and 100°, and the principle which he assumed for the reckoning of other temperatures was to call equal those differences of temperature for which differences of pressure of the air in his normal thermometer are equal. Thus he was led to a definition of temperature expressed by the following formula—

$$t = 100 \frac{p - \pi}{p_{100} - \pi}, \quad (1),$$

where π denotes the pressure one atmo, and p and p_{100} the pressures of the air of the normal thermometer at the temperatures denoted by t and by 100 respectively, the latter being the temperature of steam rising from water boiling under the pressure of one atmo. The most accurate observations which he could make Regnault found for his "normal air" $p_{100} = 1.3665 \times \pi$. Hence his thermometric formula becomes

$$t = 100 \frac{p - \pi}{1.3665 \times \pi - \pi} = 273.85 \left(\frac{p}{\pi} - 1 \right) \quad (2)$$

§ 25. Regnault complied with his normal air thermometer thermometers on the same plan of constant volume, but with air at other than the normal density of 1 atmo, and with other gases than air, also air and gas thermometers on the plan of constant apparent volume as measured in a glass bulb and stem; also a thermometer founded simply on the dilatation of mercury, also thermometers of mercury in different kinds of glass, each graduated on the glass stem with divisions corresponding to exactly equal volumes of the base, also overrunning thermometers (thermomètres à dévèsement), in which a bulb with a short piece of fine stem was perfectly filled with mercury at 0° and the quantity of mercury expelled by the high temperature to be measured was weighed, instead of being volumetrically measured by divisions of a long stem as in the ordinary thermometer.

The whole of this thermometric investigation is full of scientific interest, and abounds with results of great practical value in respect even of the minutest details of Regnault's work. It will be found fully described in the first of his three volumes, entitled *Relation des Expériences entreprises par ordre du Ministre des Travaux Publics et sur la proposition de la Commission centrale des Machines à Vapeur pour Déterminer les Principales Lois et Données Numériques qui entrent dans le Calcul des Machines à Vapeur*, which were published at Paris in 1847, 1862, and 1870. Here we can but state some of the most important of the general conclusions—

- (1) The air thermometers with pressure at 0° of from 44 to 149 centimes of mercury agreed perfectly with the normal air thermometer calculated according to the same formula (2), and nearly the same numerical coefficient 273.85. A slightly larger value 273.98 (or 0.05663-2) gave the best agreement for the 44 cm pressure, and the somewhat smaller value 273.7 (or 0.05667-) for the pressure 149 cm.
- (2) The hydrogen gas thermometer, with pressure one atmo at 0°, and with its indications calculated according to

formula (2) but with a different numerical coefficient,¹ agreed perfectly with the normal air thermometer from 0° to 325°.

(3) The carbonic acid gas thermometer with pressure 46 cm at 0°, and its indications calculated with the coefficient 271.59 (003682⁻¹), agreed perfectly with the normal air thermometer from 0° to 308°.

(4) The carbonic acid gas thermometer with pressure, at 0°, 7½ centimetres (at nearly 1 atm), calculated with the coefficient 270.64 (003695⁻¹) to make it agree with the normal air thermometer at 100°, gave numbers somewhat too large for all temperatures from 200° to 323°. The difference seemed to rise to a maximum at about 180°, when it was about 1°, and to diminish so as to be only about ½° at the highest temperatures of the comparison. Two sulphurous acid gas thermometers, with pressures 59 cm and 76 cm at 0°, calculated with coefficients 263.6 (003704⁻¹) and 261.4 (003825⁻¹) respectively to make them agree at 100° with the normal air thermometer, each gave numbers too small for the higher temperatures by differences increasing gradually from 3° at 140° to 3° at 350°.

(5) Air and gas thermometers calculated according to differences of pressure of the gas kept at the same apparent volume (that is to say, with the bounding mercury column at a constant mark on the glass stem of the thermometer) gave numbers too small at the higher temperatures by differences gradually increasing up to 2½° at 350° in the case of *Chaux le Roi* crystal, and half glass without lead, and to as much as 3½° in the case of ordinary glass.

In connexion with these observations Regnault remarks that the greatest cause of uncertainty in his air thermometer is the allowance for expansion of the glass. It was only by most carefully made special experiments² on each particular bulb and tube, to determine its expansion throughout the range for which it was to be used, that he succeeded in obtaining the great accuracy which we find in his results, according to which the probable error, whether by his normal air thermometer, or by other air or gas thermometers of those tried above, agrees with it perfectly, was not more than from 1 to 15 of a degree for any temperature up to 350°.

(6) The mercury-in-glass thermometers which Regnault generally used for comparison with his normal air thermometer were overflowing thermometers, because he found that with such he could more easily obtain the very minute accuracy at which he aimed than with the ordinary volumetric thermometers, but the formula by which he calculated temperature from the overflowing thermometer was adapted to give exactly the same result as would have been obtained by the ordinary thermometer with divisions on the stem corresponding to equal volumes of the bore. It must be remembered, however, that this perfect agreement between the volumetric and overflowing thermometers would not be found unless the expansion of the bulb and tube were uniform and isotropic throughout.

(7) The general results of Regnault's comparisons of mercury thermometers with his normal air thermometer.

¹ Instead of the 003695 of his normal air thermometer, Regnault states that for his hydrogen thermometer he used 003653 (which would make the coefficient in formula (2) be 276.82 instead of 275.85). But this must surely be a mistake, as he found 0036678 for the "coefficients of dilatation" of hydrogen calculated from its increase of pressure in constant volume, and 0036515 for the coefficient of dilatation observed directly for hydrogen under constant pressures of from 1 to 15 mm (pp. 78, 80, 91, 116, 116), and he nowhere speaks of having found any smaller value than 003661 for hydrogen.

² These experiments were made by finding the weight of mercury contained in each bulb and tube at several different temperatures throughout the range through which it was to be used, and thence calculating the bulk according to the density of mercury for the different temperatures found by his independent investigation of the absolute dilatation of mercury by the hydrometric method, this method being independent of the expansion of the containing glass or other solid

was given by himself in a diagram of curves from which the accompanying is copied on a reduced scale (fig. 3).

It shows that at a temperature of 320° the independent mercury thermometer stands at 329.8°, the thermometer of mercury in Chaux le Roi crystal at 327.26°, and the thermometer of mercury in ordinary glass at 321.8°, and that the independent mercury thermometer and the mercury in Chaux le Roi crystal stand 10° higher than the normal air thermometer at the temperatures by it of 323° and 315° respectively.

§ 26 The curve for the independent mercury thermometer is merely Regnault's graphic representation of his experiments on the absolute expansion of mercury (*Relation des Expériences*, vol. I p. 328). It shows that the addition of bulk given to the same mass of mercury under constant pressure by elevation of temperature is for the same difference of temperatures as indicated by his normal air thermometer regularly greater and greater the higher the temperature.

§ 27 It is interesting to see by the diagram that at the high temperatures all the mercury thermometers keep nearer to the air thermometer than does the independent mercury thermometer, and that the mercury in ordinary soft glass keeps much nearer to the air thermometer than does the mercury in the hard Chaux le Roi glass. We infer that, still reckoning temperature by the air thermometer, we have regular augmentation of expansion at the high temperatures in all the different glasses, each greater than the augmentation of expansion of mercury, and that this augmentation is greater in the soft ordinary glass than in the hard Chaux le Roi glass, being in the ordinary glass great enough to overcompensate in the resulting thermometric indication the augmenting expansion of the mercury from 100° to 245°, while above 245° in the ordinary glass thermometer, and at all temperatures above 100° in the Chaux le Roi thermometer, the compensation is only partial.

Between 0° and 100° the independent mercury thermometer stands regularly lower than the air thermometer by as great a difference as 35° at 50°, where it is a maximum. The curves for the mercury-in-glass thermometers are not shown between 0° and 100°, but it is clear from the diagram that the Chaux le Roi thermometer must, like the independent mercury thermometer, stand lower than the air thermometer, but by a smaller difference, probably only about 2° at 50°, and the ordinary glass thermometer higher than the air thermometer from 0° to 100° by a difference which may be 2° or 3° at 50°. This last inference from the diagram is confirmed by Regnault's table of results facing page 227 of his first volume.

§ 28 In the best modern thermometers the graduations are actually engraved on the glass, but in most popular thermometers, and in many for scientific investigation, they are on an attached scale of wood or ivory, or brass, or paper. Some of the best popular thermometers are the German bath thermometers, in which the graduation is on a paper scale guarded by being enclosed in a wide glass tube hermetically sealed round the stem and over the bulb of the glass which contains the mercury, in the manner shown in fig. 4.

Fig. 3

Fig. 4

The graduation is clearer and more easily read in this kind of thermometer than in any other. The complete protection of the paper scale against damp and damage afforded by its hermetically sealed glass envelope gives a perennially enduring quality to this form of thermometer,¹ such as is possessed by no others except those graduated on the glass, and the lightness of the paper renders its proper attachment to the inner stem, by gum or otherwise, thoroughly trustworthy, when once well done by the maker of the instrument.

Ordinary scientific thermometers measure mercury in glass

For scientific purposes the paper scale was too cheap, and common, and good, to satisfy the ideas of those instrument makers who in Germany and France substituted the heavy graduated slab of opal glass for the paper, while still adhering to the bath thermometer pattern in hermetically enclosing this scale in an outer containing glass tube,—very unnecessarily, as the glass scale, unlike the paper scale, does not require any such protection.

This is now, however, a thing of the past. At the present time all high-class scientific thermometers are graduated on the glass of the stem without any attached scale of other material. Except in respect to ease of reading the indications this simplest form is, both for popular and for scientific purposes, superior even to the German bath thermometer with hermetically sealed paper scale, and this will be the form intended when we speak of a mercury thermometer, or a spirit thermometer, or a liquid thermometer, without any special qualification.

§ 29 *Properties of Matter concerned in Liquid Thermometers*—The indications of the liquid thermometers depend not only upon the expansion of the liquid with heat, they are seriously modified by the expansion experienced also by the containing solid. The instrument in fact consists of a glass measure measuring the bulk of a liquid. If the bulk of the hollow space in the glass and the bulk of the liquid expand by the same amount, the apparent bulk of the liquid as thus measured will remain unchanged. Now, supposing the glass to be perfectly homogeneous and isotropic (see art. ELASTICITY, §§ 38, 39, and chap. I. of Mathematical Theory), and the bulb to be free from internal strain, the glass will, when warmed uniformly, expand equally in all directions, and the volume of the hollow space will be altered in the same ratio as the volume of the glass itself. Hence the indications of the thermometer depend on a difference between the expansion of the glass and the expansion of the liquid.

§ 30 To define exactly the indications of a thermometer founded on the expansion of a fluid, let the volume of the bore of the stem between two consecutive divisions be called for brevity a *degree measure*. The degree measure is habitually made as nearly as possible equal throughout the scale in the best mercury-in-glass thermometers, and, as we shall see (§ 62), it ought to be so in an air thermometer to give indications agreeing with the absolute thermodynamic scale nearly enough for the most accurate practical thermometry. But in practical spirit-thermometers the divisions are made to correspond as nearly as may be to degrees of a standard mercury or air

thermometer, and the degree measures are therefore (Table II. below) larger and larger from the lower to the upper end of the scale. For the purpose, however, of comparing the thermometric performances of different liquids, we shall suppose the degree measure to be of equal volume throughout the scale in each case.

Let N be the number of degree measures contained in the volume of the bulb and stem up to the point marked zero on the scale, and let D denote the volume, at any temperature t , of the degree measure reckoned in absolute units of volume. The volume of the bulb and stem up to zero will be ND . On the supposition of perfect isotropy and freedom from strain in the glass, N will be independent of the temperature and D/D_0 will be the ratio of the volume of any portion of the glass at temperature t to its volume at the tempera-
ture t_0 when, called zero, we denote the volume of the degree measure when the glass is at this zero temperature. Let now I_1 and I_2 denote the volumes of the whole liquid in a thermometer at the two temperatures t and 0 , we have $I_2 = ND_0$. And if s be the number of scale divisions marking the place of t , the equal surface in the thermometer tube, we have $I_1 = (N + s)D$. Hence

$$I_1/I_2 = (1 + s/N)D/D_0. \text{ Hence } s = N \left(\frac{I_1/I_2}{D/D_0} - 1 \right). \text{ Hence, if } \Delta I$$

denote augmentation of bulk of the liquid, and ΔD augmentation of bulk of each degree division of the stem, when temperature is raised from 0 to t , each reckoned in terms of the bulk of zero temperature, we have

$$s = N \left(\frac{1 + \frac{\Delta I}{I_2}}{1 + \frac{\Delta D}{D_0}} - 1 \right) = N \frac{\Delta I - \frac{I_2}{D_0} \Delta D}{1 + \frac{\Delta D}{D_0}}$$

This is the formula for the ordinary liquid thermometer. It is also applicable to the constant pressure air thermometer, in which, with proper instrumental means to keep the pressure constant, air is allowed to expand or contract with elevation or depression of temperature, and its volume is measured in a properly shaped glass measuring vessel. We may arbitrarily determine to take s as the number for the temperature which is indicated by any one particular thermometer of this kind, for instance, a methyl butyrate thermometer, or an alcohol thermometer, or a mercury or an air thermometer. But if $s = t$ for any one individual thermometer, it cannot be exactly so for any other. In the first advances towards accurate thermometry it was taken so for the mercury-in-glass thermometer, and by general consent it was continued so until it was found (§ 25) that different mercury-in-glass thermometers, each made with absolute accuracy, differ largely in their reckonings of temperature.

§ 31 *Numerical Thermometry*—In § 12 above, a perfectly definite and very simple basis for numerical thermometry was described, not as having been adopted in practice, but as an illustration of a very general principle upon which reckoning of temperature may be done in numbers. This principle is this: Two definite temperatures depending on properties of some particular substance or substances are first fixed upon and marked by two arbitrary numbers, as, for instance, the temperature of melting ice marked zero, and the temperature of steam issuing from boiling water under atmospheric pressure of exactly one atmosphere marked 100. Then any intermediate temperature t is obtained by taking t parts of water at 100° and $(100 - t)$ parts at 0° and mixing them together. As said in § 12 this method is limited to temperatures at which liquid water can be obtained, and therefore practically it is only applicable between the melting point of ice and the boiling point of water, under ordinary atmospheric pressure.

§ 32 Any other liquid of permanent chemical constitution might be used instead of water as the thermometric substance in thermometry founded on mixture, so even by mixtures might a powdered solid. Oil if used instead of water would have the advantage of being available for higher temperatures, but want of perfect definiteness and constancy of chemical constitution is a fatal disqualification for it as the fundamental thermometric substance for ther-

¹ Provided it is never exposed to "hitting" temperatures (or temperatures high enough to produce partially destructive distillation of the paper). Instrument makers ignoring this caution have actually made it with graduation extending to much temperature for kitchen use. The result is that it gets injured to the extent of partially burning the hermetically sealed paper, and befogging the inner surface of the glass envelope, by applying it to test the temperature of melted fat in cooking. For this purpose the simple scientific thermometer with graduation on the glass stem is proper.

Thermometer defined to make constant this scale of water

momety by mixtures. Liquid mercury might be used with the advantage of being available for both higher and lower temperatures than water, through a much wider range indeed than other water or oil. For most thermometric substance for the method of mixtures both water and mercury, in the conditions of approximate purity in which they are easily obtained in abundance, have a paramount advantage over all other liquids, in that enough approximation to perfect definiteness and constancy of constitution to give practically perfect thermometric results.

Different
equally

is the most
practicable
assumption

§ 33 In §§ 12, 21, 25, 30, 31, 32, several distinct definitions of numerical reckoning of temperature have been given. In each of these the differences of temperature are to be called equal and defined specially, and this is the essence of the thermometric scale in each case (the marking of 0° and 100° for the "freezing" and "boiling" points being common to all as a matter of practical usage and not an essential of the thermometric principle in any case). Thus in §§ 12, 31, and 32 differences of temperature are called equal which are produced by the communication of equal quantities of heat to a given quantity of the particular thermometric substance chosen—water, for example, or mercury, in other words (§ 68 below), this thermometric system is chosen so as to make the specific heat of a particular thermometric substance the same for all temperatures. Again in § 24 differences of temperature are called equal for which the differences of pressure are equal in air of the particular density which air has if its pressure is one atmosphere when its temperature is "freezing." This is Regnault's "normal thermometry." In § 25 (1), (2), (3), (4), other reckonings of temperature differing essentially from this, though, as Regnault's experiments proved, by but very small differences, are given simply by the substitution of air of other than Regnault's normal density, and of other gases than air, for the air of Regnault's normal thermometer. In § 25 (5) a thermometer founded on a complex efficiency of change of pressure and volume of a gas and change of volume of some one particular glass vessel is defined and compared with Regnault's normal thermometry, and in § 25 (6) and (7) the same is done for the ordinary mercury-in-glass thermometers, which depends on a coefficient of glass and mercury leading to the reckoning of temperature defined in § 30. Again in § 26 and § 24 (1) is indicated a system of thermometry founded on the absolute dilatation of some fluid, such as mercury or alcohol or butyrate of oxide of methyl or other permanent liquid or air, at some constant pressure, such as one atmosphere, with equal differences of temperature defined as those which give equal dilatations of the particular substance chosen as the thermometric fluid.

In which
foundation
on a particular
property of
a particular
substance

§ 34 Each of all these different definitions of temperature is founded on some particular property of a particular substance. A thermometer graduated to fulfil one of the definitions for one particular substance would not agree with another thermometer graduated according to the same definition for another substance, or according to some of the other definitions. A much more satisfactory foundation for thermometry is attained by thermodynamic science, which (see THERMODYNAMICS) gives us a definition of temperature depending on certain thermodynamic properties of matter in such a manner that if a thermometer is graduated according to it from observation of one class of thermal effects in one particular substance, it will agree with a thermometer graduated according to the same thermodynamic law from the same class of effects in any other substance, or from the same or from some other class of effects in another substance. Thus we have what is called the absolute thermodynamic scale. This scale is now in modern thermal science the ultimate

of temperature

scale of reference for all thermometers of whatever kind (§ 67). It is defined in §§ 35 and 37 after the following preliminary. A piece of matter which we shall call the "thermometric body" or "thermometric substance" must be given, and at each instant it must be throughout at one temperature, whatever operations we perform upon it. For simplicity we shall suppose it to be of one substance throughout. It may be all solid, or it may be partly solid and the remainder gaseous (as the contents of a wholly frozen cyphorus¹ or any other form of closed vessel full of ice and vapour of water, but with no air), or it may at one particular temperature in the course of its use be partly solid and partly liquid and partly gaseous (as the contents of a partially frozen cyphorus), or it may be partly liquid and partly gaseous (as the contents of an unfrozen cyphorus or of a "philosophical hammer"),² or it may be all liquid, or it may be all gas, or it may be all fluid at a temperature above the Andrews' "critical temperature."³ If it be all solid it may be under any homogeneous stress (ELASTICITY, Mathematical Theory, part I, chap. 1), but in any case we suppose for simplicity the stress to be homogeneous throughout, and therefore if the thermometric body be partly solid and partly fluid, the stress in the solid as well as in the fluid must be uniform pressure in all directions. To avoid excluding the case of all solid from our statements, we shall use generally the word stress, which will mean normal pressure reckoned in number of units of force per unit of area in every case in which the whole or any part of the thermometric body is fluid, and will denote this or any other possible stress when the thermometric body is all solid.

§ 35 (1) Alter the bulk or shape of the thermometric substance till it becomes warmer to any desired degree. (2) Keeping it now at this higher temperature, alter bulk or shape farther, and generate the heat which the substance takes to keep its temperature constant, by stirring water, or a portion of the substance itself, if it is partly fluid, and measure the quantity of work spent in this stirring. (3) Bring it back towards its original bulk and shape till it becomes cooled to its original temperature. (4) Keeping it at this temperature, reduce it to its original bulk and shape, carrying off, by a large quantity of water, the heat which it must part with to prevent it from becoming warmed. Find by a special experiment how much work must be done to give an equal amount of heat to an equal amount of water by stirring. Then the ratio of the first measured quantity of work to the second is the ratio of the higher temperature to the lower on the absolute thermodynamic scale.

§ 36 The following is equivalent to § 35, and is more convenient for analytical use. It is derived from § 35 by supposing the first and third operations to be so small that the ratio defined as the ratio of the two temperatures is infinitely nearly unity, and conversely § 35—our first form of definition of absolute temperature—may be derived from the second, which is to be now given, by passing through a finite range of temperature by successive infinitesimal steps, and applying the second definition to each step.

§ 37 Let the thermometric body be infinitesimally warmed by stirring a portion or the whole of itself if it be partially or wholly fluid, or by stirring a quantity of fluid in space around it if it be all solid, and during the process let the stress upon the body be kept unchanged. The body expanding or contracting or changing its shape with the heat, as the case may be, does work upon the surrounding material by which its stress is maintained

¹ See CYPHURUS LIQUID, MATTER (PROPERTIES OF), and STEAM.
² Ibid.
³ Ibid.

Second definition of absolute temperature. — For the ratio of the amount of work thus done to the amount of work spent in the stirring. For brevity we shall call this the work-ratio. Again, let the stress be infinitesimally increased, the thermometric body being now for the time enclosed in an impenetrable envelope so that it may neither gain nor lose caloric. It will rise (or fall) in temperature in virtue of the augmentation of stress. The ratio of this infinitesimal elevation of temperature to the whole absolute temperature is equal to the work-ratio multiplied into the ratio of the infinitesimal augmentation of stress to the whole stress.

§ 38 To show how our definition of absolute temperature is to be applied in practice take the following examples. Example 1. — Any case in which the thermometric substance is part in one condition and the remainder in another of different densities, as part solid and part vapour, or part solid and part liquid, or part liquid and part steam. In this last case, as explained above (§ 34), we suppose the stress to be uniform pressure in all directions.

Let p be its amount, and let t be the absolute temperature corresponding to this pressure. Let σ be the ratio of the density of the substance in the denser portion, ρ the density of the rarer portion, and let the quantity of work required to generate the heat taken to convert unit mass of the substance from the lower to the higher condition (or the "latent heat" of transition from the lower to the higher condition per unit mass of the substance, and if the dynamical equivalent of the thermal unit in which σ is measured). The work done by the substance in passing from the denser to the rarer condition per unit volume of the latter is $p(1-\sigma)$, and the amount of work required to generate the heat taken in doing so is $\frac{p}{\rho}\sigma$. Hence the work-ratio of our second definition is

$$\frac{p(1-\sigma)}{\frac{p}{\rho}\sigma} \quad (1)$$

Let now the pressure be increased by an infinitely small quantity $d\sigma$, and the substance being still in the two conditions but at uniform temperature throughout, let dt be the corresponding rise in temperature. We have by the definition (§ 37)

$$\frac{dt}{t} = \frac{p(1-\sigma) d\sigma}{\frac{p}{\rho}\sigma} \quad (2)$$

Hence

$$\frac{1}{t} \frac{dt}{d\sigma} = \frac{1-\sigma}{\sigma}$$

Hence by integration

$$\log \frac{t}{t_0} = \int_{\sigma_0}^{\sigma} \frac{(1-\sigma) d\sigma}{\sigma} \quad (3)$$

or

$$t = t_0 e^{\int_{\sigma_0}^{\sigma} \frac{(1-\sigma) d\sigma}{\sigma}}$$

steam
thermo-
meter

§ 39 Fig. 6 represents a thermometer constructed to show absolute temperature on the plan of example 1, § 38, realized for the case of water and vapour of water as thermometric substance. The containing vessel consists of a tube with cylindrical bulb like an ordinary thermometer, but, unlike an ordinary thermometer, the tube is bent in the manner shown in the drawing. The tube may be of from 1 to 2 or 3 millims bore, and the cylindrical part of the bulb of about ten times as much. The length of the cylindrical part of the bulb may be rather more than $\frac{1}{10}$ of the length of the straight part of the tube. The contents, water and vapour of water, are to be put in and the glass hermetically sealed to enclose them, with the utmost precautions to obtain pure water as thoroughly freed from air as possible, after better than the best manner of instrument makers in making cryophorous and water barometers. The quantity of water left in at the sealing must be enough to fill the cylindrical part of the bulb and the horizontal branch of the tube. When in use the straight part of the tube must be vertical with its closed end up, and the part of it occupied by the manometric water-column must be kept at a nearly enough definite temperature by a sur-

¹ In the case of full the elevation of temperature is to be regarded as negative, and in this case the "work-ratio" is negative also.

rounding glass jacket tube of ice water. This glass jacket-tube is wide enough to allow little lumps of ice to be dropped into it from its upper end, which is open. By and of an india-rubber tube connected with its lower end, and a little movable piston, as shown in the drawing, the level of the water in the jacket is kept from a few inches above to a quarter of an inch below that of the interior manometric column. Thus, by dropping in lumps of ice so as always to keep some unmelted ice floating in the water of the jacket, it is easy to keep the temperature of the top of the manometric water column exactly at the freezing temperature.

As we shall see presently, the manometric water below its free surface may be at any temperature from freezing to 10° C above freezing without more than $\frac{1}{10}$ per cent of hydrostatic error. The temperature in the vapour-space above the liquid column may be either freezing or anything higher. It ought not to be lower than freezing, because, if it were so, vapour would condense as hoar frost on the glass, and evaporation from the top of the liquid column would other cryophorousness (see FIGURE and THERMODYNAMICS) freeze the liquid there, or would cool it below the freezing point.

§ 40 The chief object of keeping the top of the manometric column exactly at the freezing point is to render perfectly definite and constant the steam pressure in the space above it.

A second object of considerable importance when the bore of the tube is so small as one millimetre is to give constancy to the capillary tension of the surface of the water. The elevation by capillary attraction of ice-cold water in a tube of one millimetre bore is about 7 millims. The constancy of temperature provided by the surrounding ice water will be more than sufficient to prevent any perceptible error due to inequality of this effect. To avoid error from capillary attraction the bore of the tube ought to be very uniform, if it is so small as one millimetre. If it be three millimetres or more, a very rough approach to uniformity would suffice.

A third object of the ice water jacket, and one of much more importance than the second, is to give accuracy to the hydrostatic measurement by keeping the density of the water throughout the long vertical branch definite and constant. But the density of water at the freezing point is only $\frac{1}{10}$ per cent less than the maximum density, and is the same as the density at 8° C, and therefore when $\frac{1}{10}$ per cent is an admissible error on our thermometric pressure, the density will be nearly enough constant with any temperature from 0° to 10° C throughout the column. But on account of the first object mentioned above the very top of the water column must be kept with exceeding exactness at the freezing temperature.

§ 41 In this instrument the "thermometric substance" (§ 34) is the water and vapour of water in the bulb, or more properly speaking the portions of water and vapour

Fig. 6

of water infinitely near their separating interface. The rest of the water is merely a means of measuring hydrostatically the fluid pressure at the interface. When the temperature is so high as to make the pressure too great to be conveniently measured by a water column, the hydrostatic measurement may be done, as shown in the annexed drawing (fig. 7), by a mercury column in a glass tube, surrounded by a glass water jacket not shown in the drawing, to keep it very accurately at some definite temperature so that the density of the mercury may be accurately known.

The simple form of steam thermometer represented with figured dimensions in fig. 6 will be very convenient for practical use for temperatures from freezing to 60°. Through this range the pressure of water-steam, reckoned in terms of the balancing column of water of maximum density, increases (Table V), from $6\frac{1}{2}$ to 202.3 centimetres; and for this therefore a tube of a little more than 2

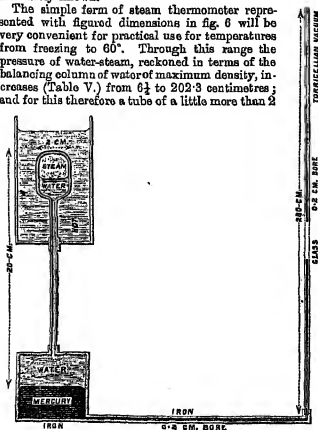

Fig. 6.

metres will suffice. From 60° to 140° the pressure of steam now reckoned in terms of the length of a balancing column of mercury at 0° increases from 14.88 to 271.8 centimetres; and for this a tube of 280 centimetres may be provided. For higher temperatures a longer column, or several columns, as in the multiple manometer, or an accurate air pressure-gauge, or some other means, such as a very accurate instrument constructed on the principle of Bourdon's metallic pressure-gauge, may be employed, so as to allow us still to use water and vapour of water as thermometric substance.

High-pressure steam thermometer.

§ 43. At 230° C., the superior limit of Regnault's high-pressure steam experiments, the pressure is 27.63 atmos, but there is no need for limiting our steam thermometer to this temperature and pressure. Suitable means can easily be found for measuring with all useful accuracy much higher pressures than 27 atmos. But at so high a temperature as 140°, vapour of mercury measured by a water column, as shown in the diagram (fig. 8), becomes available for purposes for which one millimetre to the degree is a sufficient sensibility. The mercury-steam-pressure thermometer, with pressure measured by water-column, of dimensions shown in the drawing, serves from 140° to 280° C., and will have very ample sensibility through the upper half of its scale. At 280° its sensibility

will be about $4\frac{1}{2}$ centimetres to the degree! For temperatures above 280° sufficient sensibility for most purposes is obtained by substituting mercury for water in that simplest form of steam thermometer shown in fig. 6, in which the pressure of the steam is measured by a column of the liquid itself kept at a definite temperature. When the liquid is mercury there is no virtue in the particular temperature 0° C., and a stream of water as nearly as may be of atmospheric temperature will be the easiest as well as the most accurate way of keeping the mercury at a definite temperature. As the pressure of mercury steam is at all ordinary atmospheric temperatures quite imperceptible to the hydrostatic test when mercury itself is the balancing liquid, that which was the chief reason for fixing the temperature at the interface between liquid and vapour at the top of the pressure-measuring column when the balancing liquid was water (§ 40) has no weight in the present case; but, on the other hand, a much more precise

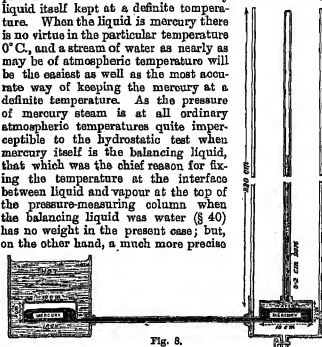

Fig. 8.

definiteness than the ten degrees latitude allowed in the former case for the temperature of the main length of the manometric column is now necessary. In fact, a change of temperature of 2.2° in mercury at any atmospheric temperature produces about the same proportionate change of density as is produced in water by a change of temperature from 0° to 10°, that is to say, about $\frac{1}{100}$ per cent; but there is no difficulty in keeping, by means of a water jacket, the mercury column constant to some definite temperature within a vastly smaller margin of error than 2.2°, especially if we choose for the definite temperature something near the atmospheric temperature at the time, or the temperature of whatever abundant water supply may be available. If the vertical tube for the pressure-measuring mercury column be 830 centimetres long, the simple mercury-steam thermometer may be used up to 520° C., the highest temperature reached by Regnault in his experiments (Table V. below) on mercury-steam. By using an iron bulb and tube for the part of the thermometer exposed to the high temperature, and for the lower part of the measuring column to within a few metres of its top, with glass for the upper part to allow the mercury to be seen, a mercury-steam-pressure thermometer can with great ease be made which shall be applicable for temperatures giving pressures up to as many atmospheres as can be measured by the vertical height available. The apparatus may of course be simplified by dispensing with the Torricellian vacuum at the upper end of the tube, and opening the tube to the atmosphere, when the steam-pressure to be measured is so great that a rough and easy barometer observation gives with sufficient accuracy the air-pressure at the top of the measuring column. The easiest, and not necessarily in precise the least accurate, way of measuring very high pressures of mercury-steam will be by enclosing some air above the cool pressure-measuring column of mercury, and so making it into a compressed-air pressure-gauge, it being understood that the law of compression of the air under the pressures for which it is to be used

in the gauge is known by accurate independent experiments such as those of Regnault on the compressibility of air and other gases.

§ 43 The water-steam thermometer may be used, but somewhat precariously, for temperatures below the freezing point, because water, especially when enclosed and protected as the portion of it in the bulb of our thermometer, may be cooled many degrees below its freezing point without becoming frozen, but, not to speak of the uncertainty or instability of this peculiar condition of water, the instrument would be unsatisfactory on account of insufficient thermometric sensitivity for temperatures more than two or three degrees below the freezing point. Hence, to make a steam thermometer for such temperatures some other substance than water should be taken, and none seems better adapted for the purpose than sulphurous acid, which, in the apparatus represented with figured dimensions in the accompanying diagram (fig. 9), makes an admirably convenient and sensitive thermometer for temperatures from $+20^{\circ}$ to something far below -30° , as we see from the results of Regnault's measurements (Table I).

§ 44 To sum up, we have in § 39 43 a complete series of steam-pressure thermometers, of sulphurous acid, of water, and of mercury, adapted to give absolutely definite and highly sensitive thermometric indications throughout the wide range from something much below -30° to considerably above 520° of the centigrade scale. The graduation of the scales of these thermometers to show absolute temperature is to be made by calculation from formula (3) of § 38, when the requisite experimental data, that is to say, the values of σ and ρ for different values of p throughout the range for which each substance is to be used as thermometric fluid are available. Hitherto these requisites have not been given by direct experiment for any one of the three substances with sufficient accuracy for our thermometric purpose through any range whatever.

Water, naturally, is the one for which the most accurate and complete information has been obtained. For it Regnault's experiments have given, no doubt with great accuracy, the values of p (the steam pressure) and of κ (the latent heat of steam per unit mass) for all temperatures reckoned by his normal air thermometer, which we now regard merely as an arbitrary scale of temperature, through the range from -30° to $+230^{\circ}$. If he, or any other experimenter, had given us with similar accuracy through the same range the values of ρ (the density of steam) and σ (the ratio of the density of steam to the density of water in contact with it), for temperatures reckoned on the same arbitrary scale, we should have all the data from experiment required for the graduation of our water-steam thermometer to absolute thermodynamic scale. For it is to be remarked that all reckoning of temperature is eliminated from the second member of formula (3), and that in our use of it Regnault's normal thermometer has merely been referred to for the values of ρ and of $1 - \sigma$, which correspond to stated values of p . The arbitrary constant of integration, ϵ_0 , is truly arbitrary. It will be convenient to give it such a value that the difference of values of t between the

freezing point of water and the temperature for which p is equal to one atm. shall be 100° , as this makes it agree with the centigrade scale in respect to the difference between the numbers measuring the temperatures, which on the centigrade scale are marked 0° and 100° . We shall see (§ 56 below) that indirectly by means of experiments on hydrogen gas this assignment of the arbitrary constant of integration would give 273 for the absolute temperature 0° C., and 373 for that of 100° C. Meanwhile, as said above, we have not the complete data from direct experiments even on water steam for graduating the water steam thermometer, but on the other hand we have, from experiments on air and on hydrogen and other gases, data which allow us to graduate indirectly any continuous intrinsic thermometer (§ 19 above) according to the absolute scale, and we shall see that by thus indirectly graduating the water-steam thermometer, we learn the density of steam at different temperatures more accurately than it has hitherto been made known by any direct experiments on water-steam itself.

§ 45 Merely viewed as a continuous intrinsic thermometer, the steam thermometer, in one or other of the forms described above to suit different parts of the entire range from the lowest temperatures to temperatures somewhat above 520° , is no doubt superior in the conditions for accuracy specified in § 16 to every other thermometer of any of the different kinds hitherto in use, and it may be trusted more surely for accuracy than any other as a thermometric standard when once it has been graduated according to the absolute scale, whether by practical experiments on steam, or indirectly by experiments on air or other gases. In fact, the use of steam-pressure measured in definite units of pressure, as a thermoscopic effect, in the steam thermometer is simply a continuous extension to every temperature of the principle already practically adopted for trying the temperature which is called 100° on the centigrade scale, and it stands on precisely the same theoretical footing as an air thermometer, or a mercury-in-glass thermometer, or an alcohol thermometer, or a methyl butyrate thermometer, in respect to the graduation of its scale according to absolute temperature. Any one intrinsic thermometer may be so graduated ideally by thermodynamic experiments on the substance itself without the aid of any other thermometer or any other thermometric substance, but the steam-pressure thermometer has the great practical advantage over all others, except the air thermometer, that these experiments are easily practicable with great accuracy instead of being, though ideally possible, hardly to be considered possible as a practical means of attaining to thermodynamic thermometry. In fact, for water-steam it is only the most easily obtained of experimental data, the measurement of the density of the steam at different pressures, that has not already been actually obtained by direct experiment. Whether or not, when this lacuna has been filled up by direct experiments, the data from water steam alone may yield more accurate thermodynamic thermometry than we have at present from the hydrogen or nitrogen gas thermometer (§ 44 69 below), we are unable at present to judge. But when once we have the means, directly from itself, or indirectly from comparison with hydrogen or nitrogen or air thermometers, of graduating once for all a sulphurous acid steam thermometer, water steam thermometer, or mercury steam thermometer, that is to say, when once we have a table of the absolute thermodynamic temperatures corresponding to the different steam pressures of the substances sulphurous acid, water, and mercury, we have a much more accurate and more easily reproducible standard than either the air or gas thermometers of any form, or the mercury thermometer, or any liquid thermometer can give.

In fact, the series of steam thermometers for the whole range from the lowest temperatures can be reproduced with the greatest ease in any part of the world by a person commencing with no other material than a piece of sulphur and oil to burn it in, some pure water, and some pure mercury, and with no other apparatus than can be made by a moderately skilled glass blower, and with no other standard of physical measurement of any kind than an accurate linear measure. He may assume the force of gravity to be that calculated for his latitude, with the ordinary rough allowance for his elevation above the sea, and his omission to measure with higher accuracy the actual force of gravity in his locality can lead him into no theoretical error which is not inconspicuously less than the inevitable errors in the reproduction and use of the air thermometer, or of mercury or other liquid thermometers. In temperatures above the highest for which mercury steam pressure is not too great to be practically available, nothing is hitherto invented but Deville's air thermometer with hard porcelain bulb suited to resist the high temperature is available for accurate thermometry.

Deville's
air thermo-
meter is
indicated

§ 46 We have given the steam thermometer as our first example of the thermodynamic thermometry because intelligence in the thermodynamics has been hitherto much retarded, and the student unnecessarily perplexed, and a more, quasi-scientific, has been given as a foundation for thermometry by building from the beginning on an ideal substance called perfect gas, with none of its properties realized rigorously by any real substance, and with some of them (see MATTER, LIQUID, SOLID) unknown, and utterly unassignable, even by guess. But after having been moved by this reason to give the steam-pressure thermometer as our first theoretical example, we have been led into the preceding carefully detailed examination of its practical qualities, and we have thus become convinced that though hitherto used in scientific investigations only for fixing the "boiling point," and (through an inevitable natural selection) by practical engineers for knowing the temperatures of their boilers by the pressures indicated by the Bourdon gauge, it is destined to be of great service both in the strictest scientific thermometry and as a practical thermometer for a great variety of useful applications.

§ 47 Example 2 (including example 1).—Any case in which the stress is uniform pressure in all directions. Let p and v denote the pressure and volume. The condition of the substance (single, double, or triple) may be taken to terminate when p and v are given, and it will therefore be spoken of shortly as the condition (p, v) . Let e be the energy which must be communicated to the substance to bring it from any conveniently defined initial condition (p_0, v_0) to any condition whatever (p, v) . Remark that e is a function of the two independent variables p, v to be found by experiment, and that the finding of it by experiment is a perfectly determinate practical problem, which can be carried out without the aid of any thermometer, and without any consideration whatever relating to temperature. We shall see in fact that recent practical solutions of it for many different substances have been obtained by experiment (see THERMODYNAMICS). The absolute temperature, t , is also a function of p and v to be also determined by experiment, according to the equivalent definitions of §§ 35 and 37. Let h be communicated to the substance so as to cause its volume to increase by dv , the pressure being kept constant. The energy of the body will be augmented by

$$\frac{de}{dv} dv$$

At the same time the body is expanding and pressing out the matter around it does work to the extent of

$$p dv \quad (4)$$

Hence the whole work required to generate the heat given to it amounts to

$$\left(\frac{de}{dv} + p \right) dv \quad (5)$$

¹ Practically, the best of all ready chemical means of generating sulphuric acid, from sulphuric acid by heating with copper, might be adopted in preference to burning sulphur.

Hence the ratio of (4) to (5), or

$$\frac{p}{\frac{de}{dv} + p} \quad (6)$$

is the "work value" of § 37. Hence by the distribution

$$\frac{Dv}{t} = \frac{37}{p} \frac{de}{dv} + p = \frac{dp}{dt} \quad (7),$$

where Dt denotes the change of temperature produced by any operation, the pressure by dp , and at the same time increasing the heat substance from t to $t + Dt$ by an taking heat from the sea, called Joule's method. To express this last condition analytically, let dv be the augmentation of volume (negative, of course, if dp be compressive) which it implies. The work done on the substance, by work by the pressure, from a vacuum is $-pdv$, and the energy of the substance is augmented by just this amount, because of the condition to be expressed. Hence

$$\frac{de}{dv} + p = \frac{dp}{dt} dv = -pdv \quad (8),$$

whence

$$dv = -\frac{de}{dp} dp \quad (9)$$

But

$$Dt = \frac{dt}{dp} dp + \frac{dt}{dv} dv,$$

and so we have

$$Dt = \left(\frac{dt}{dp} \frac{dp}{dv} + \frac{dt}{dv} \right) dv \quad (10)$$

Eliminating Dt/dv from this by (7) we find

$$t = \left(p - \frac{de}{dp} \right) \frac{dp}{dv} + \frac{de}{dv} \quad (11)$$

§ 48. This is a linear partial differential equation of the first order for the determination of t , supposing, as we do for the present, that e is a known function of p and v . The following graphical illustration of the well known analytical process for finding the complete solutions of such equations shows exactly how much too small a fraction of temperatures can be done, with no other data from experiment than the values of $\frac{de}{dv}$ and $\frac{de}{dp}$ as functions of p and v , and what additional information is required to fully determine t .

First remark that (11) is the condition that $\frac{1}{t}$ be a factor. Called thus, it renders $\left(p + \frac{de}{dv} \right) dv + \frac{de}{dp} dp$ a complete differential of a function of two independent variables p and v . Let ϕ be this function, — that is to say, let ϕ be such that

$$\left. \begin{aligned} \frac{d\phi}{dv} &= \frac{1}{t} \left(p + \frac{de}{dv} \right), \text{ and } \frac{d\phi}{dp} = \frac{1}{t} \frac{de}{dp} \\ \text{or } \frac{d\phi}{dv} &= \frac{p}{t} + \frac{de}{t dv} \\ \frac{d\phi}{dp} &= \frac{de}{t dp} \end{aligned} \right\} \quad (12)$$

Then every solution of the differential equation

$$\frac{d\phi}{dv} = \frac{p + \frac{de}{dv}}{t} \quad (14)$$

renders ϕ constant, and conversely, every series of values of p and v which renders ϕ constant constitutes a solution of (13). Now this is the differential equation may be solved graphically by taking p and v as rectangular coordinates of a point in a plane, and drawing the Rankine, whole series of curves which satisfy it as follows. Commence with any point and calculate for its values of p and v the value of the second member of (13). Draw through this point an infinitesimal straight line in the direction of the tangent to the curve given by the value ϕ so found for $\frac{d\phi}{dv}$. With the also values of p and v corresponding, calculate the value of $\frac{d\phi}{dp}$. Draw a second straight line through the point, perpendicular to the first, and of length equal to the value of $\frac{d\phi}{dp}$. Complete the right-angled triangle, and draw the hypotenuse. This hypotenuse is the tangent to the curve which satisfies (13) at the point.

² This function ϕ of great importance in practical thermodynamics is multiplied by t , it is equal to the excess of the energy of the substance above its mercury activity (denoted by Sir Wm Thomson, *Proceedings R.S.S.*, 1879) in the amount of work obtainable by letting the substance pass from the state (p, v) in which it is given to the zero condition (p_0, v_0) , without either taking in heat from or giving out heat to matter at any other temperature than t_0 . See THERMODYNAMICS.

to the other end of this infinitesimal line, calculate a fresh value of $\frac{dp}{dv}$, and continue the curve in the slightly altered direction thus found, and so on. Take another point anywhere infinitesimally near this curve but not in it, and draw by a similar process the curve through it satisfying the equation. Take a third point infinitely near to this second curve, and draw through it a third curve satisfying (18), and so on till the whole series of values p, v , possible for the substance in question, is filled with a series of curves one of which passes through, or infinitely nearly through, every point of the area. Assign arbitrarily a particular value of ϕ to each of these curves, then graphically find $\frac{d\phi}{dv}$ and $\frac{d\phi}{dp}$ for any or every value of p and v .

Then either of the two second forms of equation (12) gives us explicitly a value of t for any values whatever of p and v .

§ 49 The solution for t thus obtained involves the arbitrary assumption of a particular value of ϕ for each one of the series of curves which we have determined to need. Hence, to render t wholly determinate, something more must be given than p and v the function of p and v . Now the only thing that can be given respecting temperature for any particular substance before we have a time for which momentum, while the relation subsisting between p and v when the temperature is constant. This solution can, with merely a single temperature thermometer (§ 15 above), in addition to dynamical measurements, be determined for some one particular temperature, and thus, if t be known for every value of p and v is the only additional knowledge required for the determination of t for every value of p and v . For let $p=f(v)$ be the relation between p and v for some one particular temperature, t_0 . If by this we eliminate p from (12) we find

$$\frac{dp}{dv} = \frac{1}{t_0} \left[f(v) + \frac{d\phi}{dv} \right] \quad (14),$$

where $\frac{d\phi}{dv}$, when $p=f(v)$, becomes a known function of v alone.

Hence by integration we find

$$\phi = \frac{1}{t_0} \left[F(v) + U \right] \quad (15),$$

where F denotes a known function and C an arbitrary constant. Now trace the curve $p=f(v)$ on our diagram. It must generally cut every one of the previously drawn determinate isotherms. Hence equation (15), with two arbitrarily assigned constants t_0 and C , gives determinately the value of ϕ for every one of the points of the curve, and thus p and v determined for every value of p and v . Either of equations (12) then gives t determinately as a function of p and v , with only the value t_0 arbitrary. The information from experiment, regarding the properties of the thermometer substance, on which this determination is founded, consists of a knowledge of the relation between p and v for any one temperature, and of the value of t_0 for all values of p, v , (t_0 denoting the unknown value of t for some particular values p, v).

Although, theoretically, this information is obtainable by purely dynamical operations and measurements, with no other thermal guidance or test than that afforded by a single temperature thermometer (§ 15), the whole of it has not in fact been explicitly obtained for any one substance. But less than the whole of it suffices to make a perfect absolute thermometer of any given substance.

§ 50 For this purpose it is not necessary to find t for all values of p and v . It is enough to know it for all values mutually related in any manner convenient for thermometric practice. For example, if we could find t for every value of v with p constant at some one particular chosen value,—this would give a “constant pressure” absolute thermometer. Or again, if we find t for every value of p with v kept constant,—this would give us a “constant volume” absolute thermometer. Let us now examine into the restricted dynamic and thermoscopic investigations upon any particular substance, which will suffice to allow us to make of it a standard absolute thermometer of one or other of these species.

§ 51 *Dynamical and thermoscopic investigation required to graduate, according to the absolute scale, a constant-pressure thermometer of any particular fluid*.—Let a large quantity of fluid be given, and let proper mechanical means be taken to cause it to flow slowly and uniformly through a pipe, in one short length of which there is a fixed porous plug. If, as is the case with common air, nitrogen, oxygen, carbonic acid, and no doubt many other gases, the fluid leaves the plug cooler than it enters it, let there be a paddle in the stream flowing from the plug, and let this paddle be turned so as to stir the fluid and cause the temperature, when the

rapids are fairly past and the eddies due to the stirring subsided, to be the same as in the stream flowing towards the plug. When, as in the case of hydrogen and of all ordinary liquids, the fluid flows away from the plug warmer than it entered it, let a uniform stream of water be kept flowing in a separate canal outside the tube round a portion of it in which the internal flow is from the plug, and by this means let the temperature of the internal fluid be brought to equality with that which it had on entering the plug. By a separate thermodynamic experiment find how much work would have to be spent in stirring the external stream of water by a paddle to warm it as much as it is warmed by conduction from the internal fluid across the separating tube. Returning now to the internal fluid flowing towards and from the plug, let $p+\delta p$ be the pressure in the steady stream approaching the disturbed region, and p the pressure in the steady stream flowing from the disturbed region, and let δw be the quantity of work done by the paddle per unit of mass of the fluid passing by, reckoned positive in the first case, that namely in which the paddle compensates a cooling effect experienced in passing through the porous plug. In the second case— δw (in this case a positive quantity) must denote the work done by the paddle upon the supposed external stream of water in the separate thermodynamic experiment. It is to be reckoned per unit mass of the internal fluid, irrespectively of the rate of flow of the external water. Let t denote the temperature of the fluid according to the thermodynamic scale, and let δt denote the infinitely small change of temperature which it must experience to produce an infinitesimal expansion from volume v to volume $v+\delta v$ under constant pressure. We have

$$\frac{v}{t} \frac{dt}{dv} = \frac{1}{t} + \frac{1}{t} \frac{\delta w}{\delta p} \quad (16)$$

Proof.—Let $v+\delta v, v$, and $p+\delta p, p$ be respectively the amounts of the volume and of the mass of the fluid per unit mass, in the tranquil stream before and after passing the disturbed region. The work done by an ideal piston passing the fluid in towards the disturbed region is $(p+\delta p)(v+\delta v)$, and the work done by the emergent stream upon an ideal piston moving before it is pv , each reckoned per unit of mass, of the fluid. The whole work done on the fluid per unit mass by these ideal pistons is $p\delta v+\delta w$, add to this δw done by the paddle, and we find that, on the whole, an amount of work equal to $p\delta v+\delta w+p\delta v$ is done on the fluid in passing through the disturbed region. Hence δw exceeds $\delta w+p\delta v$ by this amount, that is to say,

$$-\delta w = p\delta v + \delta w + \delta w \quad (17)$$

Now the paddle and plug together set so as to render the temperatures equal in the tranquil streams at pressures p and $p+\delta p$. But if there were change of temperature its analytical expression would be

$$\delta t = \frac{dt}{dp} \delta p + \frac{dt}{dv} \delta v \quad (18)$$

Hence δv and δp are so proportioned as to make this vanish. That is to say, we have

$$\delta v = - \frac{\frac{dt}{dp} \delta p}{\frac{dt}{dv} \delta v} \quad (19),$$

and we have

$$\delta w = \frac{dp}{dv} \delta v + \frac{d\phi}{dv} \delta v,$$

hence (17) divided by δp becomes

$$\frac{dp}{dv} \frac{dt}{dv} - \frac{dp}{dv} = p \frac{dt}{dv} + v + \frac{\delta w}{\delta p} \quad (20)$$

Using this in (11) we find

$$\frac{t}{dv} \frac{dt}{dv} = v + \frac{\delta w}{\delta p} \quad (21)$$

Dividing (21) by v , and taking the reciprocal of both members, we have the equation (16) which was to be proved.

§ 52 Now if for any particular fluid at some one given pressure p , with infinitesimal excess δp above this pressure for the higher pressure in the thermodynamic experiment, we find neither heating nor cooling effect in passing through the porous plug, the middle has nothing to do, that is, $\delta w = 0$. If, with always the same pressure p , but with different values of v , that is to say, with the fluid given at different temperatures, but with pressures infinitely nearly the same, we always find the same result, $\delta w = 0$, it follows from (16) that for this particular fluid at the particular pressure of the experiment, and for all the temperatures of the experiment, we have

$$T \frac{dv}{dp} = 1 \quad (22)$$

Hence by integration

$$T = C_p \quad (23)$$

Hence we infer that with this fluid for thermometric substance, with the particular pressure of the experiment, and throughout the range of temperatures for which experiment has given us $\delta w = 0$, absolute temperature is shown on a scale graduated and numbered in simple proportion to the whole volume of the fluid.

§ 53 If the thermodynamic test repeated for the same fluid at different pressures gives still the same result, we have, for all pressures and temperatures within the range for which the supposed result $\delta w = 0$ has been found by the experiment,

$$T = f(p) v \quad (24),$$

where $f(p)$ denotes a quantity which depends only on the pressure of the fluid and is independent of its density.

§ 54 Joule and Thomson's experiments on the thermal effects of fluids in motion¹ showed that for pressures of from one to five or six atmos hydrogen gas, common air, nitrogen, oxygen, and carbonic acid, all somewhat approximately fulfil the condition of passing through the porous plug without change of temperature.—hydrogen much more approximately, carbonic acid much less approximately, than any of the others. Hence we infer that absolute temperature is somewhat approximately proportional to the volume of the fluid, if any one of these gases be used as the thermometric fluid in a constant pressure thermometer. We shall presently see that the requisite correction of this statement for the case of hydrogen is so small as to be almost within the limits of accuracy of the most accurate thermometric usage.

§ 55 In the case of common air, nitrogen, oxygen, and carbonic acid, the experiments showed a slight cooling effect upon the fluid in passing through the porous plug, in the case of hydrogen, a much smaller heating effect. According to the rigorous dynamical form of our statement of § 51, we have no right to measure these heating and cooling effects on any scale of temperature, as we have not yet formed a thermometric scale. And it is interesting to remark that in point of fact the thermodynamic experiment described in that section involves the use of a differential thermometer (§ 13) and not of any intrinsic thermometer at all, and in respect to this requisite it may be contrasted with the thermodynamic investigation of § 49 previously, which involved the use, not of any continuous thermometer, but only of a single-temperature intrinsic thermometer (§ 14). Now, instead of reckoning on any thermometric scale the cooling effect or the heating effect of passage through the plug, we have to measure the quantity of work (δw) required to annul it, in the case of the majority of gases; and in the case of hydrogen, instead of reckoning on any thermometric scale the heating effect, we

have to measure — δw as explained in § 51. The experiments as actually made by Joule and Thomson simply gave the cooling effects and heating effects shown by mercury thermometers in the tenuous stream towards and from the plug, but the very thermometers that were used had been used by Joule in his original experiments determining the dynamical equivalent of heat, and again in his later experiments by which for the first time the specific heat of air at constant pressure was measured with sufficient accuracy for our present purpose. Hence by putting together different experiments which had actually been made with these thermometers of Joule's, the operation of measuring δw , at all events for the case of air, was virtually completed. Thus according to our present view the mercury thermometers are merely used as a step in aid of the measurement of δw , and their scales may be utterly arbitrary, provided we know the quantity of work required to raise unit mass of any of the fluids concerned through the particular differences of temperature actually shown by the thermometers in the Joule and Thomson experiment. The best way of doing this of course is to take advantage of the best measurements, that is to say Regnault's, of the thermal capacity of air at constant pressure, and then to calculate according to Joule's own measurement the dynamical equivalent of the heat required to warm water through one degree of his own thermometers.

§ 56 Let K be the thermal capacity, pressure constant, of the fluid experimented on, J the dynamical equivalent of the thermal unit, and δt the cooling effect (reckoned negative when the effect is one of temperature), as measured by Joule's thermometers. We have

$$\delta w = -JK\delta t \quad (25)$$

Hence (16) becomes

$$v \frac{dv}{dp} = \frac{1}{1 + \frac{JK}{T} \frac{\delta t}{\delta p}} \quad (26)$$

The experiment showed δt to be simply proportional to δp not merely for an infinitesimal difference of pressure but for pressures up to 5 or 6 atmos. For the case of hydrogen the heating effect observed amounted, per 100 inches of mercury, to 100 of a degree centigrade at temperatures of 4° or 6° centigrade, and to 165 of a degree centigrade at temperatures of from 80° to 120° centigrade. The investigation was not carried out in sufficient detail to give any law of variation of this effect with temperature, and it was not even absolutely proved to be greater for the higher than for the lower temperature. In the calculations we may take the mean of the results for the higher and lower temperatures, say 13 per 100 inches of mercury, or 0.089 per atm. Hence if π denotes the force per unit of area in the pressure called "one atm.," we have

$$\frac{\delta t}{\delta p} = \frac{0.089}{\pi},$$

$$v \frac{dv}{dp} = \frac{1}{1 - 0.089 \frac{JK}{T\pi}} \quad (27)$$

Hence

$$\frac{dv}{v} = \frac{dp}{p - 0.089 JK/\pi}$$

which gives by integration

$$T = C(p - 0.089 JK/\pi) \quad (28)$$

The arbitrary constant C depends on the unit adopted for temperature. Let us then see that the difference between the boiling and freezing and boiling is 100 (which will make our arbitrary scale agree with the ordinary centigrade scale in respect to the difference between these two temperatures). Denote now by t_0 the absolute temperature corresponding to 0° C. The absolute temperature corresponding to 100° C will be $t_0 + 100$. Denote also by v_0 and v_{100} for the same two temperatures, the bulk of unit mass of hydrogen at any constant pressure within the limits of Joule and Thomson's experiments, say, from one to five or six atmos. Then by dividing the value of each member of (28) by C the difference of its value for 0° and 100°, we find

$$\frac{t_0}{100} = \frac{v_0 - 0.089 JK/\pi}{v_{100} - v_0} \quad (29)$$

Hence

$$t_0 = \frac{100}{K} (1 - 0.089 JK/\pi v_0) \quad (30),$$

¹ *Transactions Royal Society*, June 1855, June 1856, June 1860, and June 1862.

² Joule and Thomson, *Transactions Royal Society*, June 1860.

where E denotes the expansion of hydrogen, previous constant, from 0° to 100° C in terms of its volume at 0° , that is to say,

$$E = \frac{V_0 - V_0^0}{V_0} \quad (31)$$

Let V_0 denote what the volume would be at 0° C if the pressure were 10 instead of the actual pressure p . We have

$$E = \frac{100}{p} \left(1 - \frac{V_0}{V_0^0} \right) \frac{303 JK / (IV_0)}{V_0} \quad (32)$$

Regnault finds (*Expériences*, vol 1 p 122) that the value of $JK/(IV_0)$ for hydrogen gases within $\frac{1}{2}$ per cent with its value for common air, and for common air he finds $K = 238$. Thus with 133 g for the value of V_0 in metres (§ 9 above) we find $JK = 10079$ m.t.u. And Regnault's observations on the density of air give for IV_0 (on the height of the homogeneous atmosphere at 0° C) 7990 metres. Hence for common air, and therefore also for hydrogen, $JK/(IV_0) = 0.126$, and thus (32) becomes

$$E = \frac{100}{p} \left(1 + \frac{V_0}{V_0^0} \right) \quad (34)$$

with $c = -0.0049$ for hydrogen. For this gas expanding under constant pressure of one atm Regnault found (*Expériences*, vol 1 p 80) $K = 36613$, which gives $\frac{100}{K} = 273.18$. Hence (33), with $p_0 = V_0$, gives

$$E = 273.00 \quad (31),$$

that is to say —

§ 57 We conclude from Regnault's observations on the expansion of hydrogen from 0° to 100° C under a constant pressure of one atm, and from the small heating effect discovered in Joule and Thomson's experiments on the forcing of hydrogen through a porous plug, that the absolute temperature of melting ice is 273.00° , if the unit or degree of absolute temperature is so chosen as to make the difference one hundred between the temperatures of melting ice and of water with steam at one atm of pressure.

§ 58 An almost identical number for that most important physical constant, the absolute temperature of melting ice, is obtained from observations on common air, and a not very different number from observations on carbonic acid, the only two gases besides hydrogen for which Regnault (*Expériences*, vol 1 p 90) measured the expansion under constant pressure, and for which Joule and Thomson made their experiment on the thermal effect of passage through a porous plug. For each of these two gases the thermal effect observed was a lowering of temperature, and was found to vary at different temperatures very nearly in the inverse proportion of the square of the temperature C , by mercury thermometers, with 273 added. Hence nearly enough for use in the small term of the denominator of (26) we have, for air and carbonic acid,

$$\frac{dt}{dp} = A \left(\frac{273}{C} \right)^2 \frac{p}{p_0} \quad (35)$$

where t denotes as before absolute temperature, and A the amount of the cooling effect per atm of difference of pressure, on the two sides of the plug, at the temperature of melting ice. The values of A found for common air and carbonic acid are 275 and 1388. Regnault (*Expériences*, vol 1 p 126) finds $JK/(IV_0)$ greater for carbonic acid than for common air in the ratio of 1.39 to 1 on the average of temperatures from 0° to 210° . But he found also that the specific heat of carbonic acid varies greatly with the temperature, and, taking the mean of the values which he finds for it at 0° and 100° , p 130, as the proper mean for our present purpose, we find for $JK/(IV_0)$ a value 1.29 times its value for common air. From these experimental results we find by the mathematical process below (§ 61) still the same approximate formula (33), but with $c = -0.0026$ for common air and $c = -0.0163$ for carbonic acid. At constant pressure of one atm Regnault's measurements gave $E = 36706$ for common air, and $E = 3710$ for carbonic acid, and dividing 100 by these decimals we find respectively 272.44 and 269.5. The corrections on these

numbers by formula (33) to give the absolute temperature of freezing are accordingly $+70$ and $+14$, and the corresponding estimates for the required absolute temperatures are 273.14 and 273.9. Binging together the results in the three cases, we see them conveniently in the following table —

Name of Gas	Expansion at constant pressure from 1 to 100 m.t.u. (Regnault)	Proportion of cooling effect of forcing gas through porous plug to that of forcing gas through Thomson's apparatus	Temperature of melting ice at 1 atm	Correction from Joule and Thomson's experiment	Resulting estimate of absolute temperature of melting ice
Hydrogen	36613	-0° 039	273.18	-0° 18	273.00
Air	36706	+0° 208	272.44	+0° 70	273.14
Carbonic acid	3710	+1° 106	269.5	+4° 4	273.9

¹ Investigated in § 61 below.

The close agreement of the results from hydrogen and common air is very satisfactory, and it is interesting to see it brought about with so large a correction calculated from the Joule and Thomson effect. It is also interesting to see the sevenfold larger correction of nearly 5° bringing so nearly the same result from the 1 per cent larger expansion of carbonic acid. The $\frac{1}{2}$ per cent discrepancy which remains between the results from carbonic acid and from hydrogen is not satisfactory, and requires explanation, particularly when we remark that, of five measurements by Regnault (*Expériences*, vol 1 p 84) of the expansion of carbonic acid under constant pressure of one atm, all he within $\frac{1}{2}$ per cent of the mean number 3710 which he has given, and we have taken, as his result.

Notwithstanding that the Joule and Thomson correction is so much greater for common air than for hydrogen, the result from common air is probably the most trustworthy of the three, because both Regnault's experiments and Joule and Thomson's were probably more accurate for air than for either of the other two gases. The true result to one place of decimals may therefore be considered as most probably being 273.1°, but the probability that it is nearer 273.1° than 273.0° is scarcely enough to make it worth while to try in any ordinary thermodynamic calculations any other number than 273°, which is exactly that found from hydrogen.

§ 59 The real meaning of our result 273.1° for the absolute temperature of melting ice, expressed without any choice of degrees or units for temperature, is that the ratio of the temperature at which vapour of water has a pressure of one atm to the temperature at which ice melts is $273.1/273.1$. Still another way of saying the same thing, this time eliminating all numerical reckoning of temperature, is (see THERMODYNAMICS) as follows —

FOR EVERY HUNDRED UNITS OF HEAT CONVERTED INTO DETERMINED BY A PERFECT THERMODYNAMIC ENGINE, 273.1 ARE TAKEN FROM THE SOURCE, AND 273.1 ARE REJECTED TO THE REFRIGERATOR, IF THE TEMPERATURE OF THE SOURCE BE THAT AT WHICH STEAM OF WATER HAS A PRESSURE OF ONE ATM, AND THE TEMPERATURE OF THE REFRIGERATOR THAT AT WHICH ICE MELTS.

§ 60 Integration of differential equation (26), § 56, between volume and absolute temperature for a gas, derived from the Joule and Thomson experiment.

Returning to § 56 we may write equation (26) as follows: —

$$\frac{dp}{dt} = -J \frac{p}{T} \quad (36)$$

For each of the five gases experimented on, namely, common air, oxygen, nitrogen, carbonic acid, hydrogen, the experiment showed that for all pressures up to five or six atmos, dp/p was sensibly independent of the pressure, but that it varied very considerably with the temperature. Hence, if we put $dt/p = dT/p$, which will

Evaluation of the absolute temperature corresponding to 100° C to the absolute temperature on the corresponding scale to 0° C

of perfect engine source and refrigerator at these temperatures

thus denote the cooling effect per atm. of differential pressure, as a function of the temperature, and is independent of the whole pressure. With this notation ($\delta\theta$) becomes

$$\frac{d\theta}{dt} = -\frac{1}{T} \frac{dK}{d\theta}$$

This is a linear equation in θ , with a second member, if for a moment we put $-\log \theta = x$. Integrating x , and multiplying x by θ , we find the complete integral,

$$v = \theta \left\{ \frac{v_0}{t_0} + \frac{1}{\theta_0} \int_{t_0}^{\theta} \frac{\theta d\theta}{t^2} \right\} \quad (37)$$

§ 61 Expansion of the gases at constant pressure, constant, calculated from the Joule and Thomson experiment. We have from equation (37)

$$\frac{v - v_0}{t_0} = \frac{t - t_0}{t_0} \left\{ 1 + \frac{1}{\theta_0} \frac{1}{t} \int_{t_0}^{\theta} \frac{\theta d\theta}{t^2} \right\} \quad (38)$$

For which of the gases experimented on, except hydrogen, θ was found to vary nearly in the inverse ratio of t^2 . Putting then $\theta = 1/(t_0 t^2)$, we find

$$t_0 \int_{t_0}^{\theta} \frac{\theta d\theta}{t^2} = 1 \left[1 - \left(\frac{t}{t_0} \right)^2 \right]$$

Hence, for these gases at pressures from 0 to 5 or 6 atmos. (38) becomes

$$\frac{v - v_0}{t_0} = \frac{t - t_0}{t_0} \left\{ 1 + \frac{1}{\theta_0} \frac{1}{t} \left[1 - \left(\frac{t}{t_0} \right)^2 \right] \right\} \quad (39)$$

This shows that the "proper mean cooling effect" (M in the table of § 55) is

$$= \frac{1}{t} \left[1 + \frac{1}{100 + t_0} + \frac{1}{100 + t_0} \left(\frac{t_0}{100 + t_0} \right)^2 \right] \Delta, \\ = \frac{1}{t} \left(1 + \frac{1}{3603} + \frac{1}{3603^2} \right) \Delta = 759 \Delta, \\ \text{which differs so little from} \\ \frac{1}{t} \left(1 + \frac{1}{3603^2} \right) \Delta = 759 \Delta,$$

the arithmetic mean of the cooling effects at 0° and 100° C., that it was simply taken the arithmetic mean for each of the other gases, as for want of knowing better we took it for hydrogen, the difference in the result would have been barely perceptible.

§ 62 Modifying (38) or (39) to suit any two temperatures, t, t' , we have

$$\frac{v - v'}{t - t'} = \frac{t - t'}{t} \left(1 + \frac{1}{\theta} \frac{1}{t} \right) \quad (40),$$

in denoting the proper mean cooling effect per atm. in the Joule and Thomson experiment (to be reckoned as negative in the case of hydrogen or any other gas, if there is any other, in which the experiment shows a heating effect). This "proper mean" may be taken as the arithmetic mean of the values for t and t' , unless $t - t'$ considerably exceeds 100.

To reduce (40) to numbers, let V_0 be the volume of unit mass of the gas when at the temperature of melting ice, and under one atm. of pressure. Regnault (vol. i. p. 303) finds that the value of K/V_0 is within 1 per cent the same for oxygen, nitrogen, and hydrogen as for common air. He also (vol. i. pp. 224-226) finds K to be the same for common air as from 1 to 12 atmos. for hydrogen, 1 to 6, for carbonic acid, 1 to 37.

No doubt similar constancy would be found for oxygen and nitrogen. Hence, as above (§ 56), for common air we will have $JK/MV_0 = 0.128$, and thus (40) becomes

$$\frac{v - v'}{t - t'} = \frac{t - t'}{t} \left(1 + \frac{V_0}{\theta} 0.128m \right) \quad (41)$$

If in this formula we take t and t' for the temperatures of 100° C. and 0° C., $(v - v')/t'$ becomes $\frac{v - v_0}{t_0}$ as 3602, and we therefore find

$$E = 3602 \left(1 + \frac{V_0}{\theta_0} 0.128m \right) \quad (42),$$

which agrees with (33) above.

§ 63 The values given by Joule and Thomson's experiment for m are -0.039° for hydrogen, $+0.208^\circ$ for air, $+0.253^\circ$ for oxygen, and $+0.240^\circ$ for nitrogen.

From these and from the previous results for carbonic acid (§ 55) we have the following table for calculating the expansion from 0° C. to 100° C. of the gases named —

Name of Gas	Expansion under constant pressure, $\frac{v - v_0}{t_0}$ (in 10^{-6})
Hydrogen	$3662 (1 - 0.0049 \frac{V_0}{V_0 \theta_0})$
Common air	$3662 (1 + 0.0026 \frac{V_0}{V_0 \theta_0})$
Oxygen	$3662 (1 + 0.0032 \frac{V_0}{V_0 \theta_0})$
Nitrogen	$3662 (1 + 0.0031 \frac{V_0}{V_0 \theta_0})$
Carbonic acid	$3662 (1 + 0.0183 \frac{V_0}{V_0 \theta_0})$

These formulæ must be exceedingly near the truth for all pressures from 0 to 6 atmos., because within this range the thermal effects in the Joule and Thomson experiment were very approximately in simple proportion to the differences of pressure on the two sides of the plug. The following table of results calculated from (43) for several pressures of from 0 to 6 atmos. is interesting as showing such different expansions for the different cases, determined by thermodynamic theory from Regnault's measurements of specific heats and Joule and Thomson's of their particular thermal effect, with absolutely no direct measurement of expansion except the one for common air at one atm., shown as the third entry of column 5 in the table. The other five entries of column 5 show a fair amount of agreement between our theoretical results and the only direct measurements by Regnault. More of direct measurement, to allow a more extensive comparison, is very desirable.

Name of Gas	Ratio of Bulk at 0° C. to Bulk supposing Pressure were 1 atm. at the same temperature	Ratio of Density at 0° C. to Density supposing Pressure were 1 atm. at the same temperature	Expansion, pressure constant from 0 to 100° C.	
			According to theory	According to direct experiment by Regnault
Hydrogen	$\frac{V_0}{V_0}$	$\frac{V_0}{V_0}$	3662	
	$\frac{1}{1/3}$	1	3600	3661.8
	$\frac{1}{1/3 \cdot 35}$	3.35	3650	3661.0
Common Air	$\frac{V_0}{V_0}$	0	3662	
	$\frac{1}{1/3}$	1	3673	3670.6
	$\frac{1}{1/3 \cdot 38}$	3.38	3694	3695.1

	$\frac{1}{1/3}$	3	3641	
	$\frac{1}{1/3 \cdot 318}$	3.318	3650	3644.5
	$\frac{1}{1/3}$	6	4016	

§ 64 We are now quite prepared to make a practical working thermometer directly adapted to show temperature on the absolute thermodynamic scale through the whole range of temperature, from the lowest attainable by any means to the highest for which glass remains solid. It is to be remarked that our investigation of § 51, and all the deduced formulæ and relative calculations, are absolutely independent of the approximate fulfilment of Boyle's law by the gases to which we have applied them, and are equally applicable without any approach to fulfilment of Boyle's law, also that the only experimental data on which are founded our special numerical conclusions of §§ 59 to 63 are Regnault's measurements of specific heats under constant pressure, and Joule and Thomson's measurements of the thermal effect of freezing through a porous plug. From these experimental data alone we see by formula (35) of § 61 how to graduate a constant pressure gas thermometer so that it shall show temperature on the absolute thermodynamic scale. Hence, notwithstanding the difficulty (§ 34 above) which Regnault found in the thermometer use of air or other gases on the system of constant pressure, and his practical preference for the constant-volume

air thermometers, it becomes of the highest importance to construct a practical constant-pressure gas thermometer. This we believe may be done by avoiding the objectionable expedient adopted by Pouillet and Regnault of allowing a portion (when high temperatures are to be measured the greater portion) of the whole gas to be pressed into a cool volumetric chamber out of the thermometric chamber proper by the expansion of the portion which remains in, and instead fulfilling the condition, stated, but pronounced practically impossible, by Regnault (*Leçons de physique*, vol. 1 pp 168, 169), that the thermometric gas "shall, like the mercury of a mercury thermometer, be allowed to expand

freely at constant pressure in a calibrated reservoir maintained throughout at one temperature." We have accordingly designed a constant pressure gas thermometer to fulfil this condition. It is represented in the accompanying drawing (Fig. 10), and described in the following section.

§ 65 The vessel containing the thermometric fluid, which in this case is to be either hydrogen or nitrogen,¹ consists in the main of a glass bulb and tube placed vertically with bulb up and mouth down, but there is to be a secondary tube of much finer bore opening into the bulb or into the main tube near its top, as may be found most convenient in any particular case. The main tube which, to distinguish it from the secondary tube, will be called the volumetric tube, is to be of large bore, not less than 2 or 3 centimetres, and is to be ground internally to a truly cylindrical form. To allow this to be done it must be made of thick well-annealed glass like that of the French glass-balled air pumps. The secondary tube, which will be called the manometric capillary, is to be of round bore, not very fine, from half a millimetre to a millimetre diameter. Its lower end is to be connected with a mercury manometer to show if the pressure of the thermometric air is either greater or less than the definite pressure to which it is to be brought every time a thermometric measurement is made by the instrument. The change of volume required to do this for every change of temperature is made and

FIG. 10.—Constant Pressure Hydrogen Thermometer

¹ Common air is inadmissible because even at ordinary temperatures its oxygen attacks mercury. The film of oxide thus formed would be very inconvenient at the surface of the mercury caulkings, round the base of the piston, and on the inner surface of the glass tube, to which it would adhere. Besides sooner or later the whole quantity of oxygen in the air must be diminished to a sensible degree by the loss of the part of it which combines with the mercury. So far as we know, Regnault did not complain of this evil in his use of common air in his normal air thermometer (see §§ 24, 25 above), nor in his experiments on the expansion of air (*Leçons de physique*, vol. 1, p. 77). Another reason for the avoidance of air or other gas containing free oxygen is to save the oil or other liquid which is interposed between it and the mercury of the manometer from being thickened or otherwise altered by oxidation.

measured by means of a micrometer screw² lifting or lowering a glass piston, fitting easily in the glass tube, and caulked air-tight by mercury between its lower end and an iron sole-plate by which the mouth of the volumetric tube is closed. To perform this mercury caulking, when the piston is raised and lowered, mercury is allowed to flow in and out through a hole in the iron sole plate by an iron pipe, connected with two mercury cisterns at two different levels by branches each provided with a stopcock. When the piston is being raised the stopcock of the branch leading to the lower cistern is closed, and the other is opened enough to allow the mercury to flow up after the piston and press gently on its lower side, without entering more than infinitesimally into the space between it and the surrounding glass tube (the condition of the upper bounding surface of the mercury in this respect being easily seen by the observer looking at it through the glass tube). When the piston is being lowered the stopcock in the branch leading from the upper cistern is closed, and the one in the branch leading to the lower cistern is opened enough to let the mercury go down before the piston, instead of being forced to any sensible distance into the space between it and the surrounding tube, but not enough to allow it to part company with the lower surface of the piston. The manometer is simply a mercury barometer of the form commonly called a siphon barometer, with its lower end not open to the air but connected to the lower end of the manometric capillary. This connexion is made below the level of the mercury in the following manner. The lower end of the capillary widens into a small glass ball or short tube of glass of about 2 centimetres in bore and 2 centimetres depth, with its lip ground flat like the receiver of an air-pump. The lip or upper edge of the open cistern of the barometer (that is to say, the cistern which would be open to the atmosphere were it used as an ordinary barometer) is also ground flat, and the two lips are pressed together with a greased leather washer between them to obviate risk of breaking the glass, and to facilitate the making of the joint mercury tight. To keep this joint perennially good, and to make quite sure that no air shall ever leak in, in case of the interior pressure being at any time less than the external barometric pressure or being augmented to be so always, it is preserved and caulked by an external mercury-jacket not shown in the drawing. The mercury in the thus constituted lower reservoir of the manometer is above the level of the leather joint, and the space in the upper part of the reservoir over the surface of the mercury, up to a little distance into the capillary above, is occupied by a fixed oil or some other practically vapourless liquid. This oil or other liquid is introduced for the purpose of guarding against error in the reckoning of the whole bulk of the thermometric gas, on account of slight irregular changes in the capillary depression of the border of the mercury surface in the reservoir.

§ 66 In the most accurate use of the instrument, the glass and mercury and oil of the manometer are all kept at one definite temperature according to some convenient and

² This screw is to be so well fitted in the iron sole plate as to be sufficiently mercury-tight without the aid of any soft material, under such moderate pressure as the greatest it will experience when the pressure shown for the thermometric gas is not more than a few centimetres above the external atmospheric pressure. When the same plan of apparatus is used for investigation of the expansion of gases, under high pressures, a greased-leather washer may be used on the upper side of the sole in the screw-hole plate, to prevent mercury from seeping round the screw. It is to be remarked that in no case will a little oozing out of the mercury round the screw while it is being turned introduce any error at all into the thermometric result, because the consequences of the measurement of the volume of the gas depending simply on the mercury being brought up into contact with the bottom of the piston, and not more than just perceptibly up between the piston and volumetric tube surrounding it.

perfectly trustworthy intrinsic thermoscope (§§ 15 and 16 above), by means of thermal appliances not represented in the drawing but easily imagined. This condition being fulfilled, the zero desired pressure of the thermometric glass is attained with exceedingly minute accuracy by working the micrometer screw up or down until the oil is brought precisely to a mark upon the manometric capillary.

In fact, if the glass and mercury and oil are all kept rigorously at one constant temperature, the only access for error is through irregular variations in the capillary depressions in the borders of the mercury surfaces. With so large a diameter as the 2 centimetres chosen in the figured dimensions of the drawing, the error from this cause can hardly amount to $\frac{1}{100}$ per cent of the whole pressure, supposing this to be one atmosphere.

For ordinary uses of our constant-pressure gas thermometer, where the most minute accuracy is not needed, the rule will still be to bring the oil to a fixed mark on the manometric capillary, and no precaution in respect to temperature will be necessary except to secure that it is approximately uniform throughout the mercury and containing glass, from lower to higher level of the mercury. The quantity of oil is so small that, whatever its temperature may be, the bringing of its free surface to a fixed mark on the capillary secures that the mercury surface below the oil in the lower reservoir is very nearly at one constant point relatively to the glass, much more nearly so than it could be made by direct observation of the mercury surface, at all events without optical magnifying power. Now if the mercury surface be at a constant point of the glass, it is easily proved that the difference of pressures between the two mercury surfaces will be constant, notwithstanding considerable variations of the common temperature of the mercury and glass, provided a certain easy condition is fulfilled, through which the effect of the expansion of the glass is compensated by the expansion of the mercury. This condition is that the whole volume of the mercury shall bear to the volume in the cylindrical vertical tube from the upper surface to the level of the lower surface the ratio $(\lambda - \epsilon)/(\lambda - \epsilon)$, where λ denotes the cubic expansion of the mercury, and ϵ the cubic expansion of the solid for the same elevation of temperature, it being supposed for simplicity of statement that the tube is truly cylindrical from the upper surface to the level of the lower surface, and that the sectional area of the tube is the same at the two mercury surfaces. The cubic expansion of mercury is approximately seven times the cubic expansion of glass. Hence

$$(\lambda - \epsilon)/(\lambda - \epsilon) = (7 - 1)/6 = 1.111$$

Hence the whole volume of the mercury is to be about 1.111 times the volume from its upper surface to the level of the lower surface, that is to say, the volume from the lower surface in the bend to the same level in the vertical branch is to be $\frac{1}{6}$ of the volume in the vertical tube above this surface. A special experiment on each tube is easily made to find the quantity of mercury that must be put in to cause the pressure to be absolutely constant when the surface in the lower reservoir is kept at a fixed point relatively to the glass, and when the temperature is varied through such moderate differences of temperature as are to be found in the use of the instrument at different times and seasons.

A sheet-iron can containing water or oil or fusible metal, with external thermal appliances of gas or charcoal furnace, or low-pressure or high-pressure steam heater, and with proper internal stirrer or stirrers, is fitted round the bulb and manometric tube to produce uniformly throughout the mass of the thermometric gas the temperature to be measured. This part of the apparatus, which will be called for brevity the heater, must not extend so far down the manometric tube that when raised to its highest tempera-

ture it can warm the caulked meniscus to as high a temperature as 40° C, because at somewhat higher temperatures than this the pressure of vapour of mercury begins to be perceptible (see Table V below), and would vitiate the thermometric use of the pure hydrogen or nitrogen of our thermometer. To secure sufficient coolness of the mercury it will probably be advisable to have an open glass jacket of cold water (not shown in the drawing) round the volumetric tube, 2 or 3 centimetres below the bottom of the heater, and reaching to about half a centimetre above the highest portion of the bottom of the piston.

§ 67 It seems probable that the constant-pressure hydrogen or nitrogen gas thermometer which we have now described may give even more accurate thermometry than Regnault's constant volume air thermometers (§ 24 above), and it seems certain that it will be much more easily used in practice.

We have only to remark here further that, if Boyle's Law were rigorously fulfilled, thermometry by the two methods would be identical, provided the scale in each case be graduated or calculated so as to make the numerical reckoning of the temperature agree at two points,—for example, 0° C and 100° C. The very close agreement which Regnault found among his different gas thermometers and his air thermometers with air of different densities (§ 25 above), and the close approach to rigorous fulfilment of Boyle's law which he and other experimenters have ascertained to be presented by air and other gases used in his thermometers, through the ranges of density, pressure, and temperature at which they were used in these thermometers, renders it certain that in reality the difference between Regnault's normal air thermometer and thermometry by our hydrogen gas constant-pressure thermometer must be exceedingly small. It is therefore satisfactory to know that for all practical purposes absolute temperature is to be obtained with very great accuracy from Regnault's thermometric system by simply adding 273 to his numbers for temperature on the centigrade scale. It is probable that at the temperatures of 250° or 300° C (or 523 or 573 absolute) the greatest deviation of temperature thus reckoned from correct absolute temperature is not more than half a degree.

§ 68 The thermometric scale being now thoroughly established in theory and practice (§§ 33–69 and §§ 18–30), we are prepared to define, without any ambiguity, the expressions thermal capacity and specific heat with reference to matter at any temperature and in any physical condition.

Definition 1—The thermal capacity of a body (whether it be a portion of matter homogeneous throughout or of heterogeneous substance in two different conditions as liquid or solid, or solid and vapour of solid, or a piece of apparatus consisting of different parts as glass and metals, and containing as the case may be liquids or gases,—subject only to the condition that the whole matter considered is at one temperature) is the quantity of heat required to raise its temperature by one degree on the absolute thermodynamic scale.

Definition 2—The specific heat of a substance is the thermal capacity of a stated quantity of it. This stated quantity is generally understood to be the unit of mass, unless some other definite quantity is explicitly designated, as for instance the quantity of the substance which occupies unit of volume at some definite pressure and temperature, for instance, one atmosphere and temperature 273° absolute.

It is of no consequence what unit of mass is chosen provided it be the same as that which is used in defining the thermal unit, but, unless the contrary be explicitly stated, we always understand one gramme as the unit of mass and the thermal unit as the quantity of heat

required to raise one gramme of water from 273 to 274 (compare § above)

§ 69 There is scarcely any subject upon which more skilled labour in scientific laboratories, chemical and physical, has been spent than the measurement of specific heats, whether of solids, liquids, or gases. An ample and well-arranged table of results is to be found in Clarke's *Constants of Nature*, a compilation of numerical results of scientific experiments made in all parts of the world by various observers and experimenters, a most valuable aid to scientific knowledge given to the world as No 255 of the *Smithsonian Miscellaneous Collections*. It is most interesting as showing how very differently different substances behave in respect to constancy or variation of specific heat with temperature. This it shows that, according to the results of all the experimenters, the specific heats of all the substances experimented on, whether simple or compound, are very nearly constant at all events for ranges between -10° and 200° or 300° C, except the three elementary substances, boron, carbon, silicon. The specific heats of these three have been found by F. Weber to vary greatly with temperature. Thus for diamond he finds the specific heat to be 1 at 0° C and 27 at 200° C, or nearly threshold of the amount at 0° , at -50° C the specific heat is 0.63, and at $+985^{\circ}$ it is 4.59 (a curious practical commentary, we may remark in passing, on the doctrine of the calorists on specific heat referred to in § 8 above). The specific heats of carbon in its other forms of graphite and charcoal through wide ranges of temperature according to the same observer, F. Weber, are particularly interesting and significant. The approximate equality of the product of specific heat into the atomic weight for the simple metals is interesting and important, no less so is the utter want of constancy and uniformity in the corresponding product for other substances, whether simple or compound. If we were to define a metal as a substance for which through the range of temperature from 0° to 250° C the product of the specific heat into the atomic weight is not less than 5.86 and not greater than 6.93, we should include every substance commonly called a metal, and no substance not commonly called a metal, except phosphorus, and solid sulphur lately fused.

Some important results of Regnault's regarding the specific heats of gases under constant pressure have been already quoted in §§ 56, 58, and 62 above. Further information from experiments aided by thermodynamic theory, regarding specific heats of gases and vapours under constant pressure and of gases in constant volume, will be found under the heading THERMODYNAMICS. To this also, and to the articles MATTER (PROPERTIES OF), LIQUIDS, and STEAM, the reader is referred for information respecting latent heats of liquefaction of solids and of evaporation of solids and liquids, also respecting the thermal capacity of a portion of homogeneous substance in two different states, such as the water-liquid and water-steam of an ordinary cryophorus or philosophic's hammer, or of the sulphurous and liquid and steam of a sulphurous acid steam thermometer (§ 43 above).

TRANSFER OF HEAT

§ 70 When two contiguous portions of matter are at different temperatures, heat is transferred from the warmer to the colder. This process is called conduction of heat.

When two bodies at different temperatures are separated by a transparent medium, such as air, or water, or glass, or ice, heat passes from the warmer to the colder irrespectively of the temperature of the intervening medium except in so far as its transparency may in some slight degree be affected by the temperature. Thus the colder of the two bodies be-

comes actually heated above the temperature of the intervening medium if the warmer be kept above the temperature, and if heat is not otherwise drawn off from the colder body and in greater quantity than the heat entering it from the warmer. This process of transference from one body to another body at a distance through an intervening medium is called radiation of heat. The condition of the intervening matter in virtue of which heat is thus transferred is called light, and radiant heat is light if we could but see it with the eye, and not merely discern with the mind, as we do, that it is perfectly continuous in quality with the species of radiant heat which we see with the material eye through its affecting the retina with the sense of light. Thus a white hot iron in a room perfectly darkened from all other lights is seen as a brilliant white light gradually becoming reddish and less bright, until it absolutely fades from vision in a dull red glow. Long after it has ceased to be visible to the eye, the fact that heat is being transferred from it to colder bodies all round it, or above it or below it, is proved by our sense of heat in a hand or face held near it on any side or above it or below it. By considering the whole phenomenon of the white hot mass, without much of experimental investigation, we judge that there is perfect continuity through the whole process, in the first part of which the radiant heat is visible and in the second part invisible to the human eye and thorough experimental investigation confirms this conclusion. Thus radiant heat is brought under the undulatory theory of light, which in its turn becomes annexed to heat as a magnificent outlying province of the kinetic theory of heat.

§ 71 In this article we confine ourselves to a practical evaluation of rate of gain or loss of heat across the surface of an isolated solid surface in a medium such as air, and enclosed in a solid placed all at one temperature, as approximately the case with the sun and the floor, walls, and ceiling of an ordinary room. A rough approximation to the law of this action, founded on supposing the rate of motion to be in simple proportion to the excess of the temperature of the isolated solid above the temperature of the surrounding medium and enclosure was used by Fourier in those of his solutions in which surface emissivity or, as he called it, "Conductibilité extérieure," is concerned. Without adopting any hypothesis, we define thermal emissivity as the quantity of heat per unit of time, per unit of surface, per degree of excess of temperature, which the isolated body loses in virtue of the combined effect of radiation and convection by currents of air. This definition does not involve the hypothesis of simple proportionality, and the surface emissivity is simply to be determined by experiment for any given temperature of the enclosure, and any given temperature of the isolated body. Dulong and Petit made elaborate experiments on this subject but did not give any results in absolute measure.

So far as we know the first thoroughly trustworthy experiments giving emissivities in absolute measure were made in the laboratory of the natural philosophy class in the university of Glasgow by Mr D. Macfarlane in a series of experiments on the cooling of a copper ball. The results are given in Table VII. The ball experimented on was 4 centimetres in diameter, and was suspended in the interior of a double-walled tin-plate vessel. The space between the double walls of this vessel was filled with water at the temperature of the air, and the interior surface was coated with lampblack. Two thermo-electric junctions, one at the centre of the ball the other in contact with the exterior surface of the enclosure, in circuit with a sensitive mirror galvanometer, served to measure the difference of temperatures between the centre of the ball and the exterior surface of the enclosure. By this arrangement the exterior junction was kept very uniformly at a tempera-

ture of 14°C , while the other had the varying temperature of the centre of the ball. Two sets of experiments were made. In one the ball had a highly surface, in the other it was coated with soot from the flame of a lamp, and in both the air was kept moist by a saucer of water placed in the interior of the triple enclosure. The results are given in terms of the number of units of heat lost per second, per square centimetre of surface of the copper, per degree of difference between the temperatures of the two junctions.

§ 72 Returning to the conduction of heat, we have first to say that the theory of it was discovered by Fourier and sent to the world through the French Academy in his *Théorie Analytique de la Chaleur*,¹ with solutions of problems naturally arising from it, of which it is difficult to say whether they uniquely original quality, or their transcendently intense mathematical interest, or their personally important instructiveness for physical science, is most to be prized. Here we can but give the very slightest sketch of the elementary law of conduction in an isotropic substance, the mathematical expression for it in terms of orthogonal planes or curved coordinates, and a few of the elementary solutions in Fourier's theory.

§ 73 Consider a slab of homogeneous solid bounded by two parallel planes. Let the substance be kept at two different temperatures over these parallel planes by suitable sources of heat and cold. For example, let one side be kept cold by a stream of cold water, or by a large quantity of ice and water in contact with it, and the other kept warm by a large quantity of warm water or by steam blown against it. Whatever particular plans of heater and refrigerator be adopted, care must be taken that the temperature be kept uniform over the whole, or over a sufficiently large area of each side of the slab, to render the isothermal surfaces sensibly parallel planes through the whole of the slab intercepted between the two calorimetric areas, and that the temperature at each side is prevented from varying with time. It will be found that heat must continually be applied at one side and removed from the other, to keep the circumstances in the constant condition thus defined. When this constant condition of surface temperature is maintained long enough, the temperature at every point of the slab settles towards a constant limiting value, and when this limiting value has been sensibly reached by every point of the slab, the temperature throughout remains sensibly constant so long as the surface temperatures are kept constant. In this condition of affairs the temperature varies continuously from one side of the slab to the other, and it is constant throughout each interior plane parallel to the sides, in other words, the isothermal surfaces are parallel planes. Let V and V' be the temperatures in two of these isothermals and α the distance between them. The quotient $\frac{V-V'}{\alpha}$ is the average rate of variation of temperature per unit of length between these two isothermals. Let Q be the quantity of heat taken in per unit of time at a certain area A on one side, and emitted at the corresponding area of the other side of the slab, measured by proper calorimetric appliances to these areas, which we shall call the calorimetric areas of the apparatus. It will generally be found that the value of the quotient $(V-V')/\alpha$ is not the same for consecutive isothermal surfaces. For metals it is ascertained by experiment that it increases continuously from the cold side to the hot side of the thermal slab. In other words, as we shall see presently, the thermal conductivity of the substance is not generally the same at different temperatures, and for metals it is smaller the higher the temperature.

¹ A translation into English by Freeman has been recently published, in 1 vol 8vo, by the Cambridge University Press, 1879.

§ 74 Chromstances being as described in § 73, the thermal conductivity of the substance between the isothermals v and v' is the value of

$$\frac{Q\alpha}{A(v-v')} \quad (1)$$

It must be remembered that the temperatures v, v' used in this definition are temperatures of the substance itself. Some experimenters have given largely erroneous results through assuming that the temperatures of the two sides of the slab were equal to those of the calorimetric fluids, such as warm water or steam on one side, and cold water or cold water, with its temperature measured by a thermometer, on the other side. To obtain correct results, the actual temperatures at two points in the conducting body itself must be ascertained by aid of suitable thermometers, or thermometers and differential thermoscopes, applied in such a way as not sensibly to disturb the isothermal surfaces. Thus, so far as we know, has not been done by any experimenters hitherto in attempting to measure thermal conductivity directly by the method indicated in the definition, and therefore if any results obtained by this method hitherto are trustworthy, it is only in a few cases,—cases in which, unless the substance experimented upon has been of such small conducting power, and the stirring of the calorimetric fluids on its two sides so energetic, that we can feel sure that the observed or assumed temperatures of these fluids, or of the portions of them of which the temperatures have been measured by thermometers, have not differed sensibly from the temperatures of the slab at its surfaces in contact with them.

§ 75 What utter confusion has permeated scientific literature, from experiments on thermal conductivity, vitiated through non-fulfilment of this condition, is illustrated by results quoted in Everett's *Units and Physical Constants* (London, 1879), among which we find 19 for the conductivity of copper according to Péclet, and 1.1 according to Ångström (which we now know to be correct). When we look to Péclet's and Ångström's own papers the confusion becomes aggravated. Péclet, in his *Mémoire sur la détermination des coefficients de conductibilité des métaux par la chaleur*,² quotes old experiments of Clément, and others more recent of Thomas and Laurent, regarding which he gives certain details. Taking his information no doubt from Péclet's paper, Ångström gives a statement³ for the conductivity of copper, according to experimenters who had preceded him, which, with the decimal point shifted two places to the left to reduce to C G S, is as follows—

Clément	0.0281
Thomas and Laurent,	0.129
Péclet,	1.78

But Ångström did not notice that Péclet had stated the thickness of the plate experimented on by Clément to be between 2 and 3 millimetres. Péclet himself in his next sentence seems to have forgotten this when he compares the figure 23 which he had calculated from Clément's results, without taking account of the thickness of the plate, with 1.23 which he calculates from Thomas and Laurent's experiments on copper, without stating any thickness for the tube of copper on which (instead of a flat plate) they had experimented. Thus we have no data for finding what their results really were in either Péclet's or Ångström's paper, but Péclet seems to show enough regarding it to let us now feel perfectly sure that it is only a question of

² *Annales de Chimie et de Physique*, Paris, 1841.

³ In Ångström's own statement the unit quantity of heat is that required to raise 1000 grammes of water 1° . The conduction is reckoned per square metre of the copper plate per second of time, and the unit chosen for the rate of variation of temperature across the plate is 1° per millimetre. To reduce his numbers to the C G S system we must therefore multiply by $10^3 \times 10^{-4} \times 10^{-1} = 10^{-2}$.

whether it is tens or hundreds of times too small. Omitting it then from the preceding statement, completing the correction by multiplying the 0023 by 21 (assuming the thickness of the plate to be 21 millimetres, as Polet says it was between 2 and 3) to give Clément's result, and appending Ångström's result, which we now know to be correct, we have the following statement for thermal conductivity of copper in C G S units —

0067,	according to Clément
178,	" " Polet
11,	" " Ångström

§ 76 The comparison of these results is highly instructive. Clément's result is two hundred times too small, and Polet's five times too small. Clément experimented by exposing one side of a plate of copper of a square metric surface and about two and a half millimetres thick to steam at 100° C, and the other side to water at 28° C. It was assumed that the difference of temperatures between the two sides was 72°. The difference really was about 36 of a degree, as we know from the quantity of heat actually conducted through it in Clément's experiment, indicated by the amount of steam which he found to be condensed into water.

In fact, the amount of steam condensed did not differ sensibly from what it would have been if the copper plate had been infinitely thin, or its substance of infinite thermal conductivity. It is important in engineering, and in many of the arts and manufactures involving thermal processes, and particularly in that one of them of great everyday value to the human race than all the others put together, cookery, to know that for copper or iron boilers, or steam-pipes, or pots or frying-pans, the transmission of heat from radiant burning coal or charcoal, or red or white hot fireclay or other solids, and from hot air in contact with them, on one side, to hot water or steam or oil or melted fat on the other side, or hot liquid or steam on one side and cool air on the other side, is, for all practical purposes, sensibly the same as if the thermal conductivity of the metal were infinite, or its resistance to the transmission of heat nothing. The explanation is obvious to us now with the definite and sure knowledge regarding thermal conductivities of different substances and of matter in different conditions, solid, liquid, and gaseous, gained within the last twenty years. Ångström, Forbes, F. Neumann, and Tait have given, each one of them with thoroughly sufficient experimental evidence to leave no room to doubt the substantial accuracy of his results, absolute values for the thermal conductivities of copper and iron. Clausius and Maxwell have given us thermal conductivities of air and other gases, from their splendid development of the kinetic theory, which are undoubtedly trustworthy as somewhat close approximations to the true values, and which is in quite possible are more accurate than we can hope to see obtained from direct measurements of the conduction of heat through gases. J. T. Bottomley has given a trustworthy and somewhat closely accurate direct measurement of the thermal conductivity of water. From the results of these experimenters' work, reduced to uniform C G S reckoning in our table of thermal conductivities (Table VIII), we see that the thermal conductivity of iron is 80 times, and that of copper 500 times that of water. The thermal conductivity of iron is 3500 times, and that of copper is 30,000 times that of air. Hence, although the water or air at the very interface of its contact with the metal is essentially at the same temperature as the metal, there must be great differences of temperature in very thin layers of the fluid close to the interface when there is large flux of heat through the metal, and the temperature of the fluid as measured by any practicable thermometer, or

inferred from knowledge of the average temperature of the whole fluid, or from the temperatures of entering and leaving currents of fluid, may differ by scores of degrees from the actual temperature of the solid at the interface. It is remarkable that Polet, while perceiving that Clément's result was largely erroneous on this account, and improving the mode of experimenting by introducing a rotating mechanical stirrer to change very rapidly the fluid in contact with the solid, only multiplied Clément's conductivity by 30 instead of by 200, which would have been necessary to annul the error. Notwithstanding his failure to obtain accurate results for metals we have ventured to include his results for wood, mud, and solids of lower conductivity than wood, in our table, because we perceive that he was alive to the necessity for very energetic stirring of the liquid, and the mechanical means which he adopted for it, though utterly insufficient for the case of even the least conductive of the metals, were probably not so for wood and solids of lower conductivity than wood, and because it is not probable that the complication of heat generated by the stirring (which Ångström suggests as an objection to Polet's method) was in any case sufficient to produce a sensible influence upon the experimental results.

§ 77 The first correct determinations of thermal conductivities were given by Forbes in his paper on the temperature of the earth, in the *Transactions of the Royal Society of Edinburgh* for 1846, as calculated from his observations of underground temperature at three localities in the neighbourhood of Edinburgh—the trap rock of Clifton Hill, the sand of the Experimental Garden, and the sandstone of Chisleigh Quarry—by an imperfect approximate method indicated by Poisson. A more complete analytical treatment of the observational results, analysed harmonically and interpreted by application of Fourier's formula (equation (19) of Math. App.) to each term separately by W. Thomson, gave results (quoted in Table VIII below) for the conductivities, which differed but little from Forbes's approximate determinations.

§ 78 It has always seemed to us that the best mode of estimating and doubting, by an artificial imitation in metallic bar, of the actual periodic variations of underground temperature, produced by periodically varied thermal appliances at one end of the bar. The effect of loss or gain of heat through the sides (or lateral surface) of the bar (ideally annulled by a coating of ideal varnish impermeable to heat) may be practically annulled by making the period of the variation the same length as the details of the structure.

Let k be the thermal conductivity of the substance and e its thermal capacity per unit bulk. Let b be the emissivity (§ 71) of its surface. Let the bar be circular cylinders, and r the radius of its cross section. At time t , let v be the mean temperature in a cross section at distance x from the end, and θ the surface temperature at the circular boundary of this section,—all temperatures being reckoned as differences from the temperature of the surrounding medium, called sea temperature in brevity. The heat lost from the circumference of the bar between the cross sections $x - \frac{1}{2}dx$ and $x + \frac{1}{2}dx$ in time dt is $e \pi r dx \frac{d\theta}{dt}$, and the heat conducted lengthwise, across the cross section x , in the same time, is $\pi r^2 \frac{d\theta}{dx}$. Hence we readily find (see Math. App. below) as the equation of conduction of heat along the bar, very approximately if θ differs very little from v (that is to say, if the temperature is very nearly uniform throughout each cross section),

$$\frac{d^2\theta}{dx^2} - \frac{d\theta}{dx} = \left(\frac{1}{k} \frac{d\theta}{dt} \right) - \frac{2e}{r} \theta \quad (1)$$

To estimate θ , let θ' be the temperature at the centre of the cross section x , and let $\left(-\frac{d\theta}{dx} \right)$ denote the rate of decrease of temperature from within outwards in the substance of the bar close to its surface. We have clearly

$$\theta' - \theta < r \left(-\frac{d\theta}{dx} \right),$$

¹ This result was published by Polet in 1858, in a work entitled *Nouveaux documents relatifs au chauffage de la ventilation*.

and, because the emission is supplied by conduction from within,

$$\sigma' = -k \left(\frac{dv}{dx} \right) \\ \text{Hence} \\ v'' - v' < \frac{c}{v} v'$$

The value of c for a blackened globe hung within a hollow, with blackened bounding surface, is about $\frac{1}{2} \pi v$ according to Maufou's experiments (Table VII below), and considerably less for surfaces with any degree of polish. We may therefore take $\frac{1}{2} \pi v$ as a maximum value for c . The values of k for copper and iron at ordinary temperatures are, in 'G S, approximately 95 and 18. Hence, if $v = 5$ ems (as the diameter of the bar 10 ems, which is more than it is likely to be in any of our experiments), we find

$$v'' - v' < \frac{1}{890} \text{ for copper,}$$

$$\text{and} \\ < \frac{v}{100} \text{ for iron}$$

Hence the error will be practically nothing if we take $v'' = v'$. Thus, and if we suppose k to be independent of temperature, (1) becomes

$$\frac{dv}{dt} = \frac{1}{c} \frac{d^2 v}{dx^2} - \frac{2v}{c} v' \quad (2),$$

or

$$\frac{dv}{dx} = \frac{d^2 v}{dx^2} - \frac{2v}{c} v'$$

which is Fourier's equation for the conduction of heat along a bar of the circumference of a thin ring. Its solution to express simple harmonic variations of temperature produced in an infinitely long bar by properly varied thermal influences at one end is

v, R, c being arbitrary constants, — the "epoch," the semi-range, and the epoch for $x=0$, and f, g constants given by the formulae

$$\left. \begin{aligned} f &= \sqrt{\frac{1}{2k}} \left\{ (n^2 + h^2)^{1/2} - h \right\} \\ g &= \sqrt{\frac{1}{2k}} \left\{ (n^2 + h^2)^{1/2} + h \right\} \end{aligned} \right\} \quad (5)$$

For iron and copper the values of c are respectively 95 and 545. Hence, with the previously used values of k for these metals, and with $1/4000$ for c , we find $n = 2\pi/(90 \times 82)$ for copper and $n = 2$ for iron, and for either, $h = 1/17000$ nearly enough.

Suppose, for example, $v = 2$ ems, this makes $h = 1/3400$, and suppose the period to be 25 m (the greatest of those chosen by Ångström), this makes $n = 2\pi/(90 \times 82)$, or roughly $n = 1/310$ and $h/n = 1/17$. Now when h/n is small, we have approximately

$$\left. \begin{aligned} f &= \sqrt{\frac{n}{2k}} \left(1 - \frac{1}{2} \frac{h}{n} \right) \\ g &= \sqrt{\frac{n}{2k}} \left(1 + 3 \frac{1}{2} \frac{h}{n} \right), \end{aligned} \right\}$$

and therefore with the assumed numbers

$$f = \sqrt{\frac{n}{2k}} \left(1 - \frac{1}{31} \right), \text{ and } g = \sqrt{\frac{n}{2k}} \left(1 + \frac{1}{34} \right),$$

by which we see that the propagation of the variation of temperature is but little affected by the lateral surface emissivity. Little as this effect is, it is very perfectly eliminated by the relation

$$fg = 2 \frac{n}{k} \quad (6),$$

which we find from (5)

It is convenient to remark that g is the rate of diminution of the Napierian logarithm of the range, and f the rate of retardation of the epoch (reckoned in radians) per centimetre of the bar. Were there no lateral emissivity these would be equal, and the diffusivity might be calculated from each separately. This was done by William Thomson in his analysis of the Edinburgh underground temperature observations. But in the propagation of periodic variation of temperature along a bar (as of electric potential along the conductor of a submarine cable) lateral emissivity (or imperfect insulation) augments the rate of diminution of the logarithm of the amplitude, and diminishes the rate of retardation of the phase, leaving the product of the two rates unaffected, and allowing the diffusivity to be calculated from it by (6). This was carried out for copper and iron by Ångström in Sweden, and the results communicated to the Royal Swedish Academy in January 1861. German and English editions

of his paper have been published in Poggenendorff's *Annalen* for 1863, and the *Phil Mag* for 1863 (first half year). The details of the apparatus and of the actual experiments, in which Ångström had the assistance of Thalen, are sufficiently described in this paper,¹ and in a subsequent paper (Pogg *Annalen* for 1863, p 428), to allow us to feel perfect confidence in the very approximate accuracy of the results. Hence we have included them in our Table.

§ 79 The question, Does thermal conductivity vary with temperature? was experimentally investigated by Forbes about thirty years ago, and in a first provisional statement of results communicated to the British Association at Belfast in 1852 it was stated that the thermal conductivity of iron is less at high temperatures than at low. Forbes's investigation was conducted by an elaborate method of experimenting, in which the static temperature of a long bar of metal is observed after the example of the earlier experiments of Despretz, with a most important additional experiment and measurement by means of which the static result is reduced to give conductivity in absolute measure, and not merely as in Despretz's experiments to give comparisons between the conductivities of different metals. In 1861 and 1865 Forbes published results calculated from his experiments, including the first determination of absolute conductivity of a metal (iron) in absolute measure, and a confirmation of his old result that the conductivity of iron diminishes with rise of temperature. Forbes's bars have been inherited and further utilized, and bars of copper, lead, and other metals have been made and experimented upon according to the same method, by his successor in the university of Edinburgh, Professor Tait. The investigation was conducted partly with a view to test whether the electric conductivities and the thermal conductivities of different metals, more or less approximately pure, and of metallic alloys, are in the same order, and, further, if their thermal conductivities are approximately in the same proportion as their electric conductivities. The following results quoted from his paper on "Thermal and Electric Conductivity" (*Transactions R.S.E., 1878*) are valuable as an important instalment, but especially only an instalment towards the answering of this interesting question —

"Taking the inferior copper ('Copper C') as unit both for thermal and for electric conductivity, we find the following table of conductivities at ordinary temperatures, with the rough results as to specific gravity and specific heat referred to in § 16 above —

	Thermal	Electric
Copper, Green C	100	1000
Yulbes's iron	0.29	1.804
Lead	0.12	0.140
German silver	0.14	0.117

¹ The first paper is marred unhappily by two or three algebraic and arithmetical errors. One algebraic error is very disturbing to a careful reader, and might even to a hasty judgment seem to throw doubt on the validity of the experimental use which is made of the formulae. There is, however, no real foundation for any such doubt. The following little correction suffices to put the matter right. For the general term as printed in Ångström's paper read

$$e^{-\pi g \sqrt{1/\lambda}} \sin \left(\frac{2\pi x f}{T} - \pi g \sqrt{1/\lambda} + \beta' \right),$$

with the following values for g , h , $\frac{1}{\lambda}$ —

$$g = \sqrt{\frac{1}{k} \frac{H^2}{K^2} + \frac{H^2}{4K^2} + \frac{H^2}{2K}},$$

$$h = \sqrt{\frac{1}{k} \frac{H^2}{K^2} + \frac{H^2}{4K^2} + \frac{H^2}{2K}},$$

instead of these formulae without the π , as Ångström gives them.

Here we see that $g \propto \frac{1}{\sqrt{k}}$, and it is the product $g f$, that Ångström uses in his experimental application, not the separate values of either g , or f . Hence no error is introduced by his having overlooked that g is not equal to g_1 except for $\lambda = 1$.

"The agreement of these numbers is by no means so close as is generally stated, but this is no longer remarkable, for it is well known that the electric conductivity of all pure metals alters very much with the temperature, while we have seen that as regards thermal conductivity there is but slight change with either copper or lead, though there is a large change with iron. This accords with some results of my own on the electric conductivity of iron at high temperatures (*Proc. R.S.S.*, 1874-75, p. 82), and with the results of the repetition of these experiments by a party of my laboratory students."—*Proc. R.S.S.*, 1875-76, p. 629

§ 80 The absolute values of Tait's results for the five metals of the preceding list are given in CGS units in our general table. As to change of conductivity with temperature there is a discrepancy between the results of Ångström's and Tait's experiments. Tait finds but little difference in the conductivity of copper through the wide range of temperatures from 0° to 300° C, and that difference an augmentation instead of a diminution at the high temperatures, as shown in the following results (where κ is measured from 0° C) :—

Copper, Chown	0.078 (1+0.00046)
Iron, Chown	0.054 (1+0.000350)
Iron	0.016 (1—0.00144)

On the other hand, Ångström finds for copper from experiments described in his second paper referred to above, at mean temperatures of from 28° S to 71° S C, results which reduced to CGS are as follows :—

Copper	862 (1—0.001519)
Iron	199 (1—0.002874)

From the admirable method of experimenting, and the care with which experiments were carried out by himself and Thalen, it is impossible for us to doubt the validity and somewhat closely approximate numerical truth of the results. On account of the discrepancy from Tait's results it is desirable that Ångström's method should be carried out for copper through a much wider range of temperatures. This can be done with great ease from the lowest temperature obtainable by freezing mixtures to temperatures up to the melting point of copper, so excellently plastic is Ångström's method. Our proposed extension of it is to be carried out by proper thermal appliances to the end of the bar which Ångström left to itself,—appliances by which in one series of experiments it may be kept constant at —50° or —60° C, in others left to itself to take nearly the atmospheric temperature, in others kept at high temperatures limited only by the melting temperature of copper, if the experimenter desires to go so far. We would also suggest that the thermo-electric method first introduced by Wiedemann and Franz in their experiments on the static temperature of bars or wires heated at one end and allowed to lose heat by convection and radiation from their sides, (which was rejected, not, we think, judiciously, by Ångström), might be used with advantage instead of the mercury thermometers inserted in holes in the bar in Ångström's apparatus, or that, if thermometers are to be used, air thermometers in which the bulb of the thermometer is itself a very small hole in the bar experimented on and the tube a fine bore glass tube fitted to this hole, would be much preferable to the mercury thermometers hitherto employed in, we believe, all experiments except those of Wiedemann and Franz, on the conduction of heat along metallic bars.

§ 81 Fourier's ninth chapter is entitled "De la Diffusion de la Chaleur." The idea embodied in this title is the spreading of heat in a solid tending to ultimate equalization of temperature throughout it, instead of the transference of heat from one body to another by conduction through the

¹ These results are, like those given above in this section, expressed in terms of the foot and minute, but the unit of heat employed is the amount of heat required to raise the temperature of a cubic foot of the substance by 1°. In other words, these results are "diffusivities" (§ 82) in square feet per minute.

solid considered. Though Fourier makes the special subject of his chapter on "Diffusion" the conduction of heat through an infinite solid, we may conveniently regard as coming under the several designations "Diffusion of Heat" every case of thermal conduction in which the heat conducted across any part of the solid has the effect of warming contiguous parts on one side of it, or of leaving contiguous parts on the other side cooler,—in other words, every case in which the temperature of the body through which the conduction of heat takes place is varying with time, as distinguished from what Fourier calls "Uniform Motion of Heat," or the class of cases in which the temperature at every point of the body is constant. The experiments of Despretz, Despretz, Forbes and Tait, Wiedemann and Franz, others were founded on the uniform conduction of heat across slabs or along bars, and their determinations of relative and absolute conductivities were made by comparing or by measuring absolutely quantities of heat that were conducted out of the body tested. On the other hand, it is the diffusion of heat that is used in the determinations of thermal conductivity in absolute measure by Forbes and William Thomson from the periodic variations of underground temperature, in those of Ångström, from his experiments on the spreading of periodic variations of temperature through bars of iron and copper, and a series of valuable experiments a year or two later by F. Neumann, applying the same general method to bars of copper, German silver, and iron, in experiments by F. Neumann on substances of lower conductivity (coal, cast sulphur, ice, snow, frozen earth, gutstone) formed into cubes or globes of 5 or 6 inches diameter, and heated uniformly, and then left to cool in an atmosphere of lower temperature, and from time to time during the cooling explored by thermo-electric junctions imbedded in them to show their internal distribution, in similar experiments on the cooling of globes of 14 cm diameter of porphyrite trachyte by Ayrton and Perry in Japan, and in Kirchhoff and Hansemann's recent experiments,¹ to find the thermal conductivity of iron by the not well chosen method of suddenly cooling one side of a cube of iron of 14 cm, and observing the temperatures by aid of thermo-electric junctions, in several points of the line perpendicular to this side through its middle.

§ 82 When the effect of heat conducted across any part of a body in heating the substance on one side or leaving the substance on the other side cooler is to be reckoned, it is convenient to measure the thermal conductivity in terms, not of the ordinary general gramme unit of heat, but of a special unit, the quantity required to raise unit bulk of the substance in 1°. In other words, if κ be the conductivity in terms of any thermal unit, and c the thermal capacity of unit bulk of the substance, it is κ/c , not merely κ , that expresses the quantity of the substance on which the phenomenon chiefly depends. We therefore propose to give to κ/c the name of thermal diffusivity (or simply diffusivity when heat is understood to be the subject), while still using the word thermal conductivity to denote the conducting power as defined in § 78, without restriction as to the thermal unit employed. It is interesting and important to remark that "diffusivity" is essentially to be reckoned in units of area per unit of time, that its "dimensions" are L^2/T (see DIMENSIONS). Its regular CGS reckoning is therefore in square centimetres per second. In the article DIFFUSION the relation between diffusion of heat and diffusion of matter is explained. We have added diffusion of electricity through a submarine cable, which has been shown² to follow the same law as the

¹ Wiedemann's (late Poggenhoff's) *Annalen*, 1880, No. 1.

² *Proc. Roy. Soc.*, May 1866, Wm. Thomson "On the Theory of the Electric Telegraph."

Diffusion of heat

"linear" diffusion of heat, as Fourier calls the diffusion of heat when the isothermal surfaces are parallel planes. The curves of the following diagram and Tables A, B, and C show in a practically useful way the result in the course of the times noted, of from fractions of a second to thousands of millions of years, of linear diffusion of two different qualities in an infinite line from an initial condition in which there is sudden transition from one quality to the other, in the thoroughly practical cases specified in the accompanying explanations.

FIG. 11.—Diagram of Diffusion

Curve No. 1 shows temperature, or quantity of substance in solution, or potential in the conductor of a substance cable through which electricity is diffusing. Curve No. 2 shows rate per unit of distance of variation of the temperature, or of the quantity of substance in solution. Vertical ordinates are actual distances throughout the medium. Horizontal ordinates represent temperature, or quantity of diffusing substance in No. 1 curve, and rate of variation of temperature or of diffusing substance or of electric potential in No. 2 curve.

Diffusions.—Table A

Substance	Time in Seconds from the commencement of the Diffusion until the Condition represented by the Curves on the Actual Scale (4=3 Centimeters) is reached
Carbonic acid through air	8 67 seconds
Heat through hydrogen	89 of a second
" " copper	83 " "
" " iron	5 5 seconds
" " air	6 25 " "
" " underground strata	120 0 " "
" " wood	770 " "
Common salt through water	87160 " "

TABLE VI—Steam Pressures

[illegible]

MATHEMATICAL APPENDIX

Let v be the temperature at any point P specified by ξ, η, ζ according to any system of three sets of plane or curved orthogonal surfaces used for coordinates. Let $\lambda d\xi, \mu d\eta, \nu d\zeta$ be the lengths of the edges of the infinitesimal parallelepiped having P for its centre, and its sides parallel to the six surfaces $\xi = \xi_0 \pm \frac{1}{2}d\xi, \eta = \eta_0 \pm \frac{1}{2}d\eta, \zeta = \zeta_0 \pm \frac{1}{2}d\zeta$.

The rates of variation of temperature per unit of length in the directions parallel to the variations of ξ, η, ζ are respectively

$$-\frac{1}{\lambda} \frac{dv}{d\xi}, -\frac{1}{\mu} \frac{dv}{d\eta}, -\frac{1}{\nu} \frac{dv}{d\zeta}$$

Hence the fluxes across three infinitesimal rectangles having their edges parallel to the three pairs of sides of the parallelepiped, and each having its centre at P , are respectively

$$-\frac{1}{\lambda} \frac{dv}{d\xi} \mu \nu d\eta d\zeta, -\frac{1}{\mu} \frac{dv}{d\eta} \lambda \nu d\xi d\zeta, -\frac{1}{\nu} \frac{dv}{d\zeta} \lambda \mu d\xi d\eta$$

Hence the excess of the quantities of heat conducted in to the parallelepiped above those conducted out across the three pairs of faces is

$$\left\{ \frac{d}{d\xi} \left(\frac{\mu \nu}{\lambda} \frac{dv}{d\xi} \right) + \frac{d}{d\eta} \left(\frac{\lambda \nu}{\mu} \frac{dv}{d\eta} \right) + \frac{d}{d\zeta} \left(\frac{\lambda \mu}{\nu} \frac{dv}{d\zeta} \right) \right\} d\xi d\eta d\zeta \quad (1)$$

The effect of this gain of heat is to warm the matter of the parallelepiped at a rate per unit of time equal to the rate of gain of heat divided by $\lambda \mu \nu d\xi d\eta d\zeta$, the thermal capacity of the matter.

Hence

$$\frac{dv}{dt} = \frac{1}{\lambda \mu \nu} \left\{ \frac{d}{d\xi} \left(\frac{\mu \nu}{\lambda} \frac{dv}{d\xi} \right) + \frac{d}{d\eta} \left(\frac{\lambda \nu}{\mu} \frac{dv}{d\eta} \right) + \frac{d}{d\zeta} \left(\frac{\lambda \mu}{\nu} \frac{dv}{d\zeta} \right) \right\} \quad (2)$$

Thus, for the case of the uniform motion of heat ($d\lambda/dt=0$), we are first guided by LAGRANGE, to whom the generalized system of curvilinear coordinates for a point is due ("Mémoire sur les Lois de l'Équilibre des Fluides Élastiques," *Journal de Polytechnique*, vol. 11, cahen xxi). He deduced it from FOURIER's equation (8) below in terms of plane rectangular coordinates by a laborious transformation. Equation (2) we list given, noted as above, as the direct expression of FOURIER's fundamental law of conduction, by W. THOMSON (*Annals of Mathematics Journal*, Nov. 1854).

For plane rectangular coordinates we have $\lambda = \mu = \nu = 1$, and if we put x, y, z for ξ, η, ζ in this case, (2) becomes

$$\frac{dv}{dt} = \frac{d}{dx} \left(\lambda \frac{dv}{dx} \right) + \frac{d}{dy} \left(\mu \frac{dv}{dy} \right) + \frac{d}{dz} \left(\nu \frac{dv}{dz} \right) \quad (3)$$

which is FOURIER's celebrated fundamental equation. From it we may deduce by transformation the proper forms of the corresponding equation for polar coordinates, but they are more easily got direct from the equation (2) for generalized coordinates. Thus for ordinary plane coordinates r, ϕ we have, if we take these for ξ, η , ζ respectively,

$$\lambda = 1, \mu = r, \nu = \sin \theta$$

Hence (3) becomes

$$\frac{dv}{dt} = \frac{1}{r} \left\{ \frac{d}{dr} \left(k \frac{dv}{dr} \right) + \frac{1}{\sin \theta} \frac{d}{d\theta} \left(k \sin \theta \frac{dv}{d\theta} \right) + \frac{1}{r^2 \sin \theta} \frac{d}{d\phi} \left(k \frac{dv}{d\phi} \right) \right\} \quad (4)$$

If k be constant, and we put $k/a = c$, this becomes

$$\frac{dv}{dt} = \frac{c}{r^2} \left\{ \frac{d}{dr} \left(r^2 \frac{dv}{dr} \right) + \frac{d}{d\theta} \left(\sin \theta \frac{dv}{d\theta} \right) + \frac{1}{\sin \theta} \frac{d^2 v}{d\phi^2} \right\}, \quad (5)$$

or

$$\frac{dv}{dt} = k \left\{ \frac{d^2 v}{dr^2} + \frac{1}{r} \frac{dv}{dr} + \frac{1}{r^2} \left(\sin \theta \frac{d^2 v}{d\theta^2} + \frac{1}{\sin \theta} \frac{d^2 v}{d\phi^2} \right) \right\} \quad (6)$$

where $u = c/r$.

If again we take for the coordinates r, ϕ, ψ (polar coordinates in the plane perpendicular to z being denoted by r, ϕ), we have $\lambda = 1, \mu = r, \nu = 1$, and so find

$$\frac{dv}{dt} = \frac{1}{r} \left\{ \frac{d}{dr} \left(k \frac{dv}{dr} \right) + \frac{d}{d\phi} \left(r \frac{dv}{d\phi} \right) + \frac{d}{d\psi} \left(\frac{dv}{d\psi} \right) \right\} \quad (7)$$

For the case of k constant we may take it outside the brackets in each of these equations, as we have already done in (4), thus (2) becomes

$$\frac{dv}{dt} = \frac{k}{\lambda \mu \nu} \left(\frac{d^2 v}{d\xi^2} + \frac{d^2 v}{d\eta^2} + \frac{d^2 v}{d\zeta^2} \right) \quad (8)$$

or, with c for k/a , the diffusivity (§§ 81, 82),

$$\frac{dv}{dt} = c \left(\frac{d^2 v}{d\xi^2} + \frac{d^2 v}{d\eta^2} + \frac{d^2 v}{d\zeta^2} \right) \quad (9)$$

It is this rational form which, with the further restriction that c be constant, is most generally recognized as FOURIER's equation of conduction, and it is for it, with these restrictions, that his brilliant solutions were given. These solutions are available for practical use by limiting the range of temperature within which any one solution is continuously applicable to a range of temperatures within which the values of k and c are each nearly enough constant. We may expect 10° or 20° C. on each side of the mean temperature to be practically not too wide a range for any case, judging from copper and iron (§ 80), the only instances for which tabular data we have any information as to variations of both k and c with temperature.

Each of the following expressions I XVII for v satisfies FOURIER (9) or its equivalent (8), the latter will readily verify for himself. The special condition corresponding to the particular character of the particular solution is specially noted in each case.

I. Instantaneous spherical point source, a quantity Q of heat suddenly generated at the point $(0, 0, 0)$ at time $t=0$, and left to diffuse through an infinite homogeneous solid.

Every other solution is obtainable from this by summation.

$$v = \frac{Q e^{-r^2/4ct}}{8\pi^2 (ct)^{3/2}} \quad (10)$$

where

$$r^2 = x^2 + y^2 + z^2$$

Verify that $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} v dx dy dz = 4\pi \int_0^{\infty} r^2 dr = Q$, and that $v=0$ when $t=0$, unless also $x=0, y=0, z=0$.

Remark that

$$\frac{dv}{dt} = 0 \text{ when } t = \frac{r^2}{6c} \quad (11)$$

II. Constant spheroidal point source, a rate q per unit of time from an arbitrary function, $f(t)$.

$$v = \int_0^{\infty} q f(t-\chi) \frac{e^{-r^2/4c\chi}}{8\pi^2 (c\chi)^{3/2}} d\chi \quad (12)$$

The formula within the brackets shows how this obvious solution is obtainable from (11).

III. Continued point source, a rate per unit of time, at time t , an arbitrary function, $f(t)$.

$$v = \int_0^{\infty} q f(t-\chi) \frac{e^{-r^2/4c\chi}}{8\pi^2 (c\chi)^{3/2}} d\chi \quad (13)$$

IV. Time periodic spheroidal point source, a rate per unit of time at time t , $q \sin 2\pi t$.

$$v = \int_0^{\infty} q \sin 2\pi(t-\chi) \frac{e^{-r^2/4c\chi}}{8\pi^2 (c\chi)^{3/2}} d\chi = \frac{q}{8\pi^2 (c\chi)^{3/2}} \sin [2\pi t - (c\chi)^{1/2}] \quad (14)$$

Verify that v satisfies (8), also that $-\frac{dv}{dt} = g \sin 2\pi t$ when $r=0$.

V. Instantaneous spheroidal surface source, a quantity Q suddenly generated over a spheroidal surface of radius a , and left to diffuse outwards and inwards.

$$v = Q \frac{e^{-r^2/4ct} - e^{-a^2/4ct}}{8\pi^2 (ct)^{3/2}} \quad (15)$$

To prove the most easily, verify that it satisfies (8), and further verify that

$$\frac{dv}{dt} = 0 \text{ when } t = 0, \text{ unless also } r = a$$

Remark that (15) becomes identical with (10) when $a=0$, remark further that (16) is obtainable from (10) by integration over the spheroidal surface.

VI. Constant spheroidal surface source, a rate per unit of time from the whole surface, g .

$$v = \left[-\frac{g}{4\pi^2} \int_0^{\infty} \frac{e^{-r^2/4c\chi} - e^{-a^2/4c\chi}}{8\pi^2 (c\chi)^{3/2}} d\chi \right] \quad (16)$$

and

$$-\frac{dv}{dt} = g \text{ when } r = a$$

The formula within the brackets shows how this obvious solution is derivable from (15).

VII. Time-periodic spheroidal surface source, a rate per unit of time, at time t , from whole surface, $g \sin 2\pi t$.

$$v = \left[-\frac{g}{4\pi^2} \int_0^{\infty} \frac{e^{-r^2/4c\chi} - e^{-a^2/4c\chi}}{8\pi^2 (c\chi)^{3/2}} d\chi \right] \quad (17)$$

where $r < a$.

where A, B, C, D are constants determined by the conditions that

$$v = 0 \text{ when } r = a$$

and

$$-\frac{dv}{dt} = g \text{ when } r = a$$

when the two values of r exceed a and fall short of a by an infinitely small difference. Verify that v satisfies (8). Also that v is finite when $r=0$.

VIII. FOURIER's "Linear Motion of Heat", instantaneous plane source, a quantity q per unit surface, $e^{-r^2/4ct}$.

$$v = \frac{q}{2\pi^2 (ct)^{3/2}} \quad (18)$$

Verify that this satisfies (9) for the case of v independent of y and z , and that

$$\int_{-\infty}^{\infty} v dx = \sigma$$

Remark that (18) is obtainable from (16) by putting $Q/\pi a^2 = \sigma$, and $a = \infty$, or directly from (10) by integration over the plane.

IX. "Linear Motion of Heat", time periodic plane sources, rate per unit of area, per unit of time, at time t , $\sigma \sin 2\pi t$

$$\left\{ \begin{aligned} v &= -g \int_0^{\infty} dx \sin 2\pi (t-x) \frac{e^{-\sqrt{g}x}}{2\pi^2(x)} \\ &= \frac{\sigma}{(2\pi)^{3/2}} e^{-\sqrt{g}t} \sin 2\pi (t - \sqrt{g}t) - \frac{1}{2} \pi \text{ where } t > 0 \\ &= \frac{\sigma}{(2\pi)^{3/2}} e^{-\sqrt{g}t} \sin 2\pi (t + \sqrt{g}t) - \frac{1}{2} \pi \text{ where } t < 0 \end{aligned} \right\} \quad (19)$$

Verify that v satisfies $\frac{dv}{dt} = \kappa \frac{d^2v}{dx^2}$, which is what (9) becomes when v is independent of y and z , also that

$$-2\pi \frac{dv}{dx} = \sigma \sin 2\pi t \text{ when } x \text{ is infinitely small positive,}$$

and $2\pi \frac{dv}{dx} = \sigma \sin 2\pi t$ when x is infinitely small negative

X. "Linear Motion of Heat", space periodic, simple harmonic solid source, with plane isothermal surfaces. Initial distribution, $v = V \sin \pi x$, when $t = 0$. Solution for any value of t

$$v \left[-V \int_0^{\infty} d\xi \sin \pi (x - \xi) \frac{e^{-\sqrt{K}\xi}}{2\pi^2(\xi)} \right] = V e^{-Kt} \sin \pi x \quad (20)$$

Modify the integral within the brackets to make it appear as an analytical expression belonging to the general theory of images, for the case of a single image, free of images, and equating the result to the right hand member, we see that

$$\frac{1}{4\pi^2} \int_0^{\infty} d\xi \sin \pi (x - \xi) e^{-\sqrt{K}\xi} = e^{-Kt} \sin \pi x \quad (21),$$

ξ being any integer.

It is obvious that for a given x substitute jx in the second member, and in the factor $\frac{1}{4\pi^2}$ of t the integral sign of the first member, without altering its value, j being any integer, thus we have

$$\left\{ \begin{aligned} \frac{1}{4\pi^2} \int_0^{\infty} d\xi \sin j\pi (x - \xi) e^{-\sqrt{K}\xi} &= e^{-j^2 Kt} \sin j\pi x \\ \text{where } S &= \sum_{j=0}^{\infty} e^{-(\xi + \frac{2j^2 Kt}{\pi^2})} \end{aligned} \right\} \quad (22)$$

XI. "Linear Motion of Heat", space periodic arbitrary solid source, isothermal plane. Initial distribution, $v = f(x)$, when $t = 0$, f denoting an arbitrary periodic function, period 1 , so that $f(x+1) = f(x)$, taking any image. Two solutions (A), (B), derived synthetically from (10)

$$v = \frac{1}{2(\pi\kappa)^{1/2}} \int_0^{\infty} d\xi f(x - \xi) e^{-\sqrt{\kappa}\xi} \quad (23),$$

$$\text{where } S = \sum_{j=0}^{\infty} e^{-(\xi + j^2 Kt)} \quad (24)$$

(B) derived analytically and synthetically from (20)

Find $A_0, A_1, A_2, \dots, B_1, B_2, \dots$, by the harmonic analysis, to satisfy the condition

$$\left\{ \begin{aligned} f(x) &= A_0 + A_1 \cos \pi x + A_2 \cos 2\pi x + \dots \\ &+ B_1 \sin \pi x + B_2 \sin 2\pi x + \dots \\ \text{where } 0 &= \frac{2\pi x}{1} \end{aligned} \right\} \quad (25)$$

$$\text{Then } t = A_0 + \sum_{j=1}^{\infty} e^{-(2\pi^2 j^2 Kt)} \left(A_1 \cos \frac{2\pi x}{1} + B_1 \sin \frac{2\pi x}{1} \right) \quad (26)$$

XII. Uniform row of simple instantaneous plane sources. Two solutions (A) and (B)

(A), from XI (A), (23)

$$v = \frac{\sigma}{2(\pi\kappa)^{1/2}} \sum_{j=0}^{\infty} e^{-(x-j)^2 \kappa t} \quad (27)$$

The No 2 diffusion curve of § 82 is the representation of the first term ($j=0$) of this formula

(B), from XI (B), (24) and (26)

$$v = \frac{\sigma}{2} \left\{ 1 + 2 \sum_{j=1}^{\infty} e^{-\pi^2 j^2 Kt} \cos \frac{2\pi x}{1} \right\} \quad (28)$$

The comparison of these two solutions is very interesting phys-

¹ This is Fourier's $\zeta(x)$ of Art. 874 for the case of $f(x)$ a periodic function

cally, and useful antithetically. To facilitate the comparison, put

$$1/2(\pi\kappa)^{1/2} = g, \text{ and } x/2(\pi\kappa)^{1/2} = y \quad (29),$$

the two solutions become

$$\frac{dv}{dy} - g \sum_{j=0}^{\infty} e^{-\pi(j+y)^2} = 1 + 2 \sum_{j=1}^{\infty} e^{-\frac{j^2 \pi}{g}} \cos \frac{2j\pi y}{g} \quad (30)$$

The equation between the second and third member, virtually due originally to Fourier, is also an interesting formula of Jacobi's, *Fundamenta Nova Theoriae Functionum Ellipticarum*, as we may long ago pointed out by Cayley. Each formula is a series which converges for every value of y however small or however great, the first, (27), the more rapidly the less is t , the second, (28), the more rapidly the less is t . For the case of $t = 1/4\pi\kappa$, and $x=0$ (that is, $g=1$ and $y=0$), the two series become identical. For the more comprehensive case of $j=0$, but y unrestricted, the comparison gives the following very curious antithetical theorem—

$$\frac{1 + 2(e^{-\pi y^2} - e^{-4\pi y^2} + e^{-9\pi y^2} + \dots)}{g + 2(e^{-\frac{\pi}{g}y^2} - e^{-\frac{4\pi}{g}y^2} + e^{-\frac{9\pi}{g}y^2} + \dots)} = 1 \quad (31)$$

When $t = 1/4\pi\kappa$ (or $g=1$) the first solution (27) converges with so great suddenness, that three terms suffice for most practical purposes, when $t = 1/4\pi\kappa$ (or $g=1$) the second solution (28) converges with so great suddenness that one term (after the constant first term) suffices for most practical purposes. Thus by using the solution (27) for all values of t from zero to something less than $1/4\pi\kappa$, and (28) for all values greater than the greatest for which (27) is used, we have an exceedingly rapid convergence and easy calculation to find v for any value of x and t . The formula, thus used, have been of great practical value in calculating what is now known as the arrival curve of signals through a submarine cable, and in designing instruments to record it automatically and allow its telegraphic meaning to be read, or what is termed, its α value, meaning to be read by watching the motions of a spot of light. It is clear that (27) and (28) express the potential at a point at distance x from one end of a cable of length 1 , at time t from an instant when a quantity of electricity has been suddenly communicated to that end of the cable, both ends being always kept insulated α value that instant ($t=0$) is done practically by an exceedingly short contact with one pole of a voltaic battery, the other being left to earth. The value of g for $x=1$, and for all values of t from 0 to ∞ , represents the rise of the potential at the remote end towards the limiting value σ .

towards which the potential rises throughout the conductor.

XIII. (X in three dimensions.) Space triple periodic solid source, in other words $v = V \sin \pi x \sin \pi y \sin \pi z$, when $t = 0$. Solution for any value of t —

$$\left\{ \begin{aligned} v &= \frac{1}{8(\pi\kappa)^{3/2}} \int_0^{\infty} d\xi d\eta d\zeta \sin \pi (x - \xi) \sin \pi (y - \eta) \sin \pi (z - \zeta) \frac{e^{-\sqrt{\kappa}\xi}}{8\pi^3(\xi\eta\zeta)} \\ &= V \sin \pi x \sin \pi y \sin \pi z e^{-\kappa t} \end{aligned} \right\} \quad (32)$$

Remark that, as an analytical expression for the present case of the general theory of triply multiple images, the triple integral within the brackets may be written

$$\int_0^{\infty} \int_0^{\infty} \int_0^{\infty} d\xi d\eta d\zeta \sin \pi (x - \xi) \sin \pi (y - \eta) \sin \pi (z - \zeta) \frac{e^{-\sqrt{\kappa}\xi}}{8\pi^3(\xi\eta\zeta)}, \quad (33),$$

where $S = \sum_{j=0}^{\infty} \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} e^{-(\xi + \eta + \zeta + j^2 Kt + k^2 Kt + l^2 Kt)}$

s, j, k, l being any positive or negative integers

XIV and XV (X and XI in three dimensions). The formulae may be written down by inspection, from I, with X and XI for guides.

The analytical theorem, which we have obtained, according to (30), in three dimensions, is interesting to pure mathematicians. XVI. Harmonic solutions. Any distribution of heat, whether in an infinite or in a bounded solid, which keeps its type unchanged in subsiding towards uniformity, when left without positive or negative sources, except such, essentially negative, as are required to fulfil a proper boundary condition, is called a harmonic distribution, provided the temperature does not increase to infinity in any direction. The boundary condition, if the solid is bounded, is essentially that the rate of emission from the surface at every point of it varies in simple proportion to the temperature, and at such a rate per unit of temperature at each part of the surface as the solution requires. X and XIII are examples. The general condition for a harmonic solution is

$$v = f(\nabla^2 v), \quad (34),$$

² See *Quarterly Journal of Mathematics* for 1867. Note by Cayley on an article by W. Thomson, entitled "On the Calculation of Transients of the form $\int_0^{\infty} e^{-x^2} f(x) dx$ "

and this tried in (9) gives

$$\frac{1}{f(t)} \frac{d}{dt} \left(\frac{d^2 F}{dt^2} + \frac{d^2 F}{dx^2} + \frac{d^2 F}{dy^2} \right) = \dots \quad (35)$$

The first member being independent of x, y, z , and the second being independent of t , the common value of the two must be independent of x, y, z, t ; that is to say, must be an absolute constant. Let it be denoted by $-\mu$; we have

$$f(t) = C e^{-\mu t} \quad (36)$$

$$\text{and } \frac{d^2 F}{dx^2} + \frac{d^2 F}{dy^2} + \frac{d^2 F}{dz^2} + \mu F = 0 \quad (37)$$

or in terms of polar coordinates, by (8),

$$\frac{d^2 U}{dr^2} + \frac{1}{r^2} \sin \theta \frac{d}{d\theta} \left(\sin \theta \frac{dU}{d\theta} \right) + \frac{1}{r^2 \sin^2 \theta} \frac{d^2 U}{d\phi^2} + \mu U = 0 \quad (38)$$

where

$$U = A \phi(r) + B \psi(r) S_1 \quad (39)$$

where S_1 denotes a spherical surface-harmonic of order 1 , and $\phi(r), \psi(r)$, two particular solutions of the equation

$$\frac{d^2 u}{dr^2} + \left[\mu - \frac{1}{r^2} (1 + \frac{1}{2}) \right] u = 0 \quad (40)$$

Then (38) and (39) give finally

$$u = e^{-\mu r} \frac{A \phi(r) + B \psi(r) S_1}{r} \quad (41)$$

This solution is in its generality applicable to an infinite solid occupying all space except a hollow round the origin. The solid may of course be bounded externally also by a finite closed surface. If there be no hollow, A/B must fulfil the condition that $[A\phi(r) + B\psi(r)]/r$ is finite when $r=0$. If there are two boundaries, concentric spherical surfaces, with their common centre at the origin of coordinates, the boundary condition obviously requires uniform emissivity over each, but not necessarily equal for the two. If the two emissivities be denoted by h and h' , and the radii of the surfaces by a (outer) and a' (inner), the boundary conditions are

$$\left. \begin{aligned} \frac{du}{dr} &= -hv, \text{ when } r=a \\ \text{and } \frac{du}{dr} &= h'v', \text{ when } r=a' \end{aligned} \right\} \quad (42)$$

HEATH, the English form of a name given in most Teutonic dialects to the common ling or heather, but now applied to all species of *Erica*, an extensive genus of monopetalous plants, belonging to the order *Ericaceae*. The heaths are evergreen shrubs, with small narrow leaves, in whorls usually set rather thickly on the shoots; the persistent flowers have 4 sepals, and a 4-lobed campanulate or tubular corolla, in many species more or less ventricose or inflated; the dry capsule is 4-celled, and opens, in the true *Erica*, in 4 segments, to the middle of which the partitions adhere, though in the ling the valves separate at the dissepiments. The plants are mostly of low growth, but several African kinds reach the size of large bushes, and a Spanish variety, *E. arborea*, occasionally attains almost the aspect and dimensions of a tree.

One of the best known and most interesting of the family is the common heath, leather, or ling, *Calluna vulgaris*, placed by most botanists in a separate genus on account of the peculiar dehiscence of the fruit, and from the coloured calyx, which extends beyond the corolla, having a whorl of sepal-like bracts beneath. This shrub derives some economic importance from its forming the chief vegetation on many of those extensive wastes that occupy so large a portion of the more sterile lands of northern and western Europe, the usually desolate appearance of which is enlivened in the latter part of summer by its abundant pink blossoms. When growing erect to the height of a yard or more, as it often does in sheltered places, its purple stems, close-leaved green shoots, and feathery spikes of bell-shaped flowers render it one of the handsomest of the heaths; but on the bleaker elevations and more arid slopes it frequently rises only a few inches above the ground. In

From these we may find h and h' , so as to let the harmonic character of the solution be fulfilled in the substance. Or if h and h' be given, we have in (41) two equations which determine the two unknown quantities A/B and μ . Eliminating A/B , we thus find a single transcendental equation for μ , which is proved to have no imaginary or negative roots, and an infinite number of real positive roots, each $\propto (x+1)^{1/2}$. In the case of $i=0$, or temperature independent of ϕ and θ , (40) gives

$$u = A \cos r \sqrt{\frac{\mu}{\kappa}} + B \sin r \sqrt{\frac{\mu}{\kappa}}$$

For this case the transcendental equation for determining values for μ is very simple, and its roots are calculated numerically with great ease. With the further restriction of no central hollow, we must have $A=0$, so that u/r may be finite when $r=0$. This case was fully investigated by Fourier, and very beautifully worked out in his fifth chapter. The more general problem of a solid sphere, with any given initial distribution of temperature, without the restriction of temperature independent of θ and ϕ , was solved first by Poisson in the 11th chapter of his *Théorie Mathématique de la Chaleur*, in terms of the formulae (35), (38), (40) above.

XVII. The equation of the transference of heat in terms of columnar coordinates, (7) above, affords naturally another beautiful case of harmonic solution. Assume

$$v = e^{-\mu^2 z} u_1 \frac{d^2 u_1}{dx^2} + \frac{d^2 u_1}{dy^2} \quad (43)$$

we find by (7)

$$\frac{d^2 u_1}{dx^2} + \frac{1}{\rho} \frac{du_1}{dz} + \left(\frac{\rho}{\kappa} - \mu^2 - \frac{\rho^2}{\rho^2} \right) u_1 = 0 \quad (44)$$

The treatment of this equation and its integral (obviously derivable by 4 differentiations from (4), which is a Bessel's function) for the full solution of the thermal problem is most interesting, and very instructive and suggestive in respect to pure analysis. It was splendidly worked out for the case of $m=0$ and $i=0$ by Fourier in his 6th chapter, "The Motion of Heat in a Solid Cylinder," truly a masterpiece of art. When it was printed in 1821, and published after having with the rest of Fourier's work been buried alive for fourteen years in the archives of the French Academy, and when Bessel found in it so thorough an investigation and so strikingly beautiful an application of the "Bessel's Function," we can imagine the ordinary feeling towards those "qui ante nos nostra dixerunt" reversed into the pleasure of genuine admiration.

all moorland countries the ling is applied to many rural purposes; the larger stems are made into brooms, the shorter tied up into bundles that serve as brushes, while the long trailing shoots are woven into baskets. Pared up

FIG. 1.—*Erica cinerea*.

FIG. 2.—*Calluna vulgaris*.

with the peat about its roots it forms a good fuel, often the only one obtainable on the drier moors. The shiellings of the Scotch Highlanders were formerly constructed of heath stems, cemented together with peat-mud, worked into a

kind of mortar with dry grass or straw, hovels and sheds for temporary purposes are still sometimes built in a similar way, and roofed in with ling. Laid on the ground, with the flower above, it forms a soft springy bed, the luxurious couch of the ancient Gael, still gladly resorted to at times by the hill shepherd or hardy deer-stalker. The young shoots were in former days employed as a substitute for hops in brewing, while their stringency rendered them valuable as a tanning material in Ireland and the Western Isles. They are said also to have been used by the Highlanders for dyeing woollen yarn yellow, and other colours are asserted to have been obtained from them, but some writers appear to confuse the wood, *Genista tinctoria*, with the heather. The young dry-stalked shoots, and the seeds, which occur long in the cylinder, furnish the red grouse of Scotland with the larger portion of its sustenance, the ripe seeds are eaten by many birds. The tops of the ling afford a considerable part of the winter fodder of the hill flocks, and are popularly supposed to communicate the fine flavour to Welsh and Highland mutton, but sheep seldom crop heather while the mountain grasses and rushes are sweet and accessible. In recent times ling has been suggested as a material for paper, but the stems are hardly sufficiently fibrous for that purpose. The purple or fine-leaved heath, *E. caerulea*, one of the most beautiful of the genus, abounds on the lower moors, and commons of Great Britain and western Europe, in such situations being some times more prevalent than the ling. The flowers of both these species yield much honey, furnishing a plentiful supply to the bees in moorland districts, from this heath honey the Futs probably brewed the mead said by Beostus to have been made from the flowers themselves.

It was until recently supposed that no species of heath existed in America, but of late years isolated plants of ling have been found in various parts of New England, Nova Scotia, and Cape Breton, while it has been stated to occur in some abundance in several places in Newfoundland, probably in distant ages it may have had a wider range on the American continent. The whole group, as observed by Benthams, is "eminently Atlantic" in its present distribution,—of nearly 500 known species by far the greater part being indigenous to the western districts of South Africa, and nearly all the remainder limited to Europe and its adjacent islands.

The Cape heaths have long been favourite objects of horticulture. In the warmer parts of Britain several will bear exposure to the cold of ordinary winters in a sheltered border, but most need the protection of the conservatory. They are sometimes raised from seed, but are chiefly multiplied by cuttings "stuck" in sand, and afterwards transferred to pots filled with a mixture of black peat and sand, the peat should be dry and free from sourness. Much attention is requisite in watering heaths, as they seldom recover if once allowed to droop, while they will not bear much water about their roots: the heath-house should be light and well ventilated, the plants requiring sun, and soon perishing in a close or permanently damp atmosphere, in England little or no heat is needed in ordinary seasons. The European heaths succeed well in English gardens, only requiring a peaty soil and sunny situation to thrive as well as in their native localities. *E. caerulea*, *mediet-ranea*, *albicans*, *vulgata*, and the pretty cross-leaved heath of boggy moors, *E. tetralix*, are among those most worthy of cultivation. The beautiful large-flowered *St. Daboc's* heath, belonging to the closely allied genus *Menziesia*, is likewise often seen in gardens. (O P T.)

HEATHCOAT, JOHN (1788–1861), the author of important inventions for facilitating the manufacture of Buckingham or French lace, was born at Duffield near Derby in 1788. During his apprenticeship to a framesmith near

Loughborough, he made an improvement in the construction of the warp loom, so as to produce mits of a lace like appearance by means of it. He commenced business on his own account at Nottingham, but finding himself subjected to the intrusion of competing inventors he removed to Henthorn. There he diligently prosecuted his experiments, and in 1808 constructed a machine capable of producing an exact imitation of real pillow lace. This was by far the most expensive and complex textile apparatus till then existing, and in describing the process of his invention, Heathcoat said in 1836, "The single difficulty of getting the diagonal threads to twist in the allotted space was so great that, if now to be done, I should probably not attempt its accomplishment." Some time before perfecting his invention, which he patented in 1809, he removed to Loughborough, where he entered into partnership with Mr Lacy, a Nottingham manufacturer, but in 1816 their factory was attacked by the Luddites and the lace frames destroyed. The damage was assessed in the King's Bench at £10,000, but as Heathcoat declined to expend the money in the county of Leicester he never received any part of it. Undaunted by his loss, he began at once to construct new and greatly improved machines used as unoccupied factories at Tiverton, Devonshire, propelling them by water-power and afterwards by steam. His claim to the invention of the twisting and traversing lace machine was disputed, and a patent was taken out by a clever workman for a similar machine, which was decided at a trial in 1816 to be an infringement of Heathcoat's patent. He followed his great invention by others of much ability, as, for instance, contrivances for ornamenting net while in course of manufacture and for making ribbons and platted and twisted net upon his machines, improved yarn spinning frames, and methods for winding raw silk from cocoons. He also patented an improved process for extracting and refining silk. An offer of £10,000 was made to him in 1833 for the use of his processes in dressing and finishing silk nets, but he allowed the highly profitable secret to remain undivulged. In 1832 he patented a steam plough, which stood foremost in public estimation until superseded by those of Fowler and others. Heathcoat was elected member of parliament for Tiverton in 1832. Though he seldom spoke in the House he was constantly engaged on committees, where his thorough knowledge of business and sound judgment were highly valued. He retained his seat until 1850, and after two years of declining health he died in January 1861 at Bolham House, near Tiverton.

HEATING. In temperate latitudes the climate is generally such as to necessitate in dwellings, during a great portion of the year, a temperature warmer than that out of doors, and, similarly, tropical plants growing in temperate climates require artificial heat in the house in which they are preserved. Thus heating is required for health and comfort the object of the application of science is to obtain these with the greatest degree of economy. In its aspect as to health it may be assumed that no system of heating is advisable which does not provide for a constant renewal of the air in the locality warmed. In climates such as that of the United Kingdom, the temperature of living rooms should be maintained at from 54° to 68° Fahr in the daytime, the night temperature may be lower, but should not fall below 40°, and the humidity of the air as measured by the wet and dry bulb thermometers should show a difference of not less than 4° nor much exceeding 8° between the two thermometers, although with an ample supply of air a greater degree of dryness would probably not be found objectionable.

All heating apparatus depends upon the transference of heat from the fire to the various parts of the building which

it is intended to warm, and thus transfer may be effected by radiation, by conduction, or by convection. Radiant heat is emitted and absorbed in an accelerating ratio in proportion as the difference of temperature between the radiant and the recipient increases, and, with the same difference of temperature between the recipient and the radiant, the effect of the radiant will be greater according to the increased temperature of the recipient. In other words, the ratio of the emission of heat increases with the temperature. It is thus easier to effect the warming of a given space by means of a highly heated surface than by a surface emitting a lower temperature.

An open fire acts by radiation. It warms the air in a room by first warming the walls, floor, ceiling, and articles in the room, and these in turn warm the air. Therefore in a room with an open fire the air of the room is, as a rule, less heated than the walls. In this case the warming of the air depends on the capacity of the surfaces to absorb or emit heat, except that the heat received by the walls may be divided into two parts, one part heating the air in contact with the wall, and the other passing through the wall to the outer surface, where it is finally dissipated and wasted. Fireplaces are sometimes constructed to assist the warming of the air of a room. For instance, in Sylvestre's grate iron bars of which one end terminates under the fire are laid so as to form a projecting radiating hearth. The ventilating fireplace warms the fresh air before its admission into the room by means of gills cast on the back of the grate.

In a close stove, heated to a moderate temperature, the heat, as it passes from the fire, warms the surface of the materials which enclose and are in contact with the fire and with the heated gases. The materials next transfer the heat to the outer surface in contact with the air, and the air is warmed by the agency of this outer surface. If heated to high temperatures a stove gives out radiant heat, which passes through the air to warm the objects on which the rays impinge.

With hot water pipes, the heat from the water heats the inner surface of the pipe, and this surface transfers its heat to the outer surface through the material of the pipe. The rate at which the heat can pass from the inner to the outer surface, and be thus utilized instead of passing away straight into the chimney, depends on the heat evolved by the fire, on the extent of surfaces exposed to the heat and their capacity to absorb and emit heat, and on the quality of the material between the inner and the outer surface as a good or bad conductor of heat. This passage of heat through a body by conduction varies directly with the quality of material, and with the difference between the temperature of the inner surface exposed to the heat and the outer surface exposed to a cooling influence, and inversely as the thickness between the surfaces. Other things being equal, copper is a better material than iron for conveying the heat from the fire to water or air, and coverings of brickwork, wood, or woollen fabrics are better adapted than iron for retaining the heat. The property which appears more than any other to make materials good non-conductors of heat is their porosity or, and the retention of the air in their pores.

The direct warming of the air may be effected by stoves with brick or iron flues, or by hot water or steam pipes. The sizes of the heating surfaces for this object must be proportioned to the volume of air required to be warmed for ventilation, and the degree of heat to be maintained, the thickness of the material, and its capacity for absorbing and radiating heat and for transferring heat from one surface to the other. When a large volume of air is supplied and removed for ventilation, rapidly in transferring the heat from the fuel to the air is an important consideration. Brick stoves and flues are worse conductors of heat than iron stoves or flues, but the surface of a brick stove parts with the heat which reaches it somewhat more rapidly than the surface of an iron stove. The slow conducting power of the material and the greater thickness of

a brick stove prevent alterations which may take place in the fire from being felt so much as with iron stoves or flues, and therefore the brick stove varies the air more equally, without sudden variations, the air so warmed is free from objectionable elements, and where they can be avoided, the brick stove is able to use brick stoves for warming air for ventilating purposes.

With an iron flue pipe from a stove, almost the whole heat which any fuel is capable of developing may be utilized by using a sufficiently long pipe, horizontal, and the air heated by it is able to convey the products of combustion to the outer air. The heat given out by a stove pipe varies with the temperature from and to, being of course greatest at the end next the stove, while the emission of heat is very rapid, and the amount of heat given out per square foot will vary at each point as the distance from the stove increases. The proportions also into which the heat divides itself between radiation and convection vary greatly with the temperature. Thus, a pipe, one heated at the end nearest the stove to a dull red heat of 1230° Fahr., and of sufficient length to allow the heat to be diminished to 160° at the further end, it would be found that at the stove end of the flue pipe 82 per cent of the total heat emitted by the pipe is given out by radiation to the walls and only 8 per cent to the air, but at the end and the heat is nearly equally divided, the walls receiving 66 and the air 34 per cent. Taking the whole length, such a pipe, the walls would receive 74 per cent and the air 26 per cent of the heat emitted. But with a flue pipe heated to lower temperatures, the air might receive half the heat or even more. When therefore the object is to heat the walls rather than the air, the temperature of the pipes should be high, and for this purpose stove pipes are more effective than hot-water or low-pressure steam pipes. At high temperatures there will be practically little difference of effect between horizontal and vertical flues, because the heat given out is principally that due to radiation, which is independent of the form and position of the radiant. An adequate proportion of flue pipes to the form and size of the stove involves a large surface for the flue pipe, with a careful observation of proportion, as, such as 941 per cent of the heat in the fuel has been utilized.

There is, however, several serious objections to iron stoves, especially for small rooms, a long flue pipe is usually required, on this account often inadmissible, iron stove heat rapidly, and easily become red hot, and the effect produced therefore is unequal. Carbonic oxide, too, has been found in air warmed by iron stoves very highly heated. It is alleged that highly heated iron gives out oxygen from the carbonic acid and the air in contact with its surface, and thus reduce the acid to carbonic oxide.

When iron stoves or cookers are used for heating air, care should be taken to prevent the iron from attaining a high temperature, and with this object all iron stoves should have a lining of fire brick, so as to prevent the fire from coming in direct contact with the iron, such an arrangement preserves greater regularity in the heating of the air. This object may be also attained by giving the stove a large surface in proportion to the fire by means of flanges or gills to carry off the heat as fast as it is generated. Iron coated with a surface of glazed enamel would enable the heat to pass rapidly from the fire to the surface, while the enamel surface would emit the heat more rapidly than the iron surface.

Hot water pipes for warming air are free from many of the objections arising from the direct application of heat to iron, because the heat can be regulated with ease.

A high temperature may be obtained from water without generating steam by heating it under pressure. In Parkman's high-pressure system, a continuous iron tube, about 1 inch diameter, is filled with water, about one sixth of the length of the tube is coiled and placed in a furnace, and the remainder, forming the heating surface, is heated by the circulation of the water. At the highest level to which the tube is raised the water is forced into a space for expansion of the heated water equal to 5 per cent of the contents of the small tube.

Pipes may be heated by either hot water or by steam. The higher the temperature, the greater the comparative effect in warming air, therefore, with a small heating surface, steam pipes are more efficient than hot water pipes, and steam at a high pressure more efficient than low pressure steam. The efficient action of hot water pipes depends upon the upward flow of the heated and expanded water as it passes from the boiler, the passage being made as direct as possible, and so protected as to lose little heat between the boiler and the place where the heat is to be utilized. The return pipe, which brings back the water after it has been cooled down by the abstraction of heat in warming the air, should be passed into the bottom of the boiler as directly and as near as possible to the place where the heat is to be used, and as possible. The velocity of flow in the pipes will depend upon the temperature at which the water leaves the boiler, the height to which the heated water has to rise, and the temperature at which it passes down the return pipe back to the boiler. The velocity of the water apparatus will be regulated by these conditions, by the size of the pipe, and by such other conditions as affect the flow

of water in pipes. When the boiler is source of heat twenty feet above the level of the pipes for heating the air, the average temperature which can be obtained in the pipes will be lower than when the vertical column is long. The heating surface must be regulated with reference to this difference of level. It may in fact be assumed that with small pipes, the temperature being constant, the velocity of flow in the pipe necessary to furnish a given amount of heat will vary in the ratio of the length of the pipe. When the water enters through the pipes by virtue of the difference of temperature of the flow and return currents only, it is impossible to count upon a greater mean temperature of the pipes than from 160° to 180°, because above a certain temperature the water in the boiler begins to boil. To obtain a sufficient velocity of circulation for long distances, or with small differences of level, a forced circulation may be resorted to. This has been done by Messrs. Brown and Anderson at the costly lunatic asylum at Battersea, in the following manner. The whole hot water service is supplied from boilers placed at one end of the asylum buildings, which extend to a distance of several hundred yards. There are two pipes, one of them, which may be called the flow pipe, is connected directly with the boiler, the returning at the point farthest from the boiler at a dead end, the other, which may be termed the return pipe, is parallel to the first, and terminates it one end in a return which is placed at the first, above, and supplies the boiler. At the other end furthest from the boiler the second pipe also terminates in a dead end. At each provision of place, to which hot water is required to be conveyed, there is a connection between the two pipes, which can be closed or opened at will, when it is opened, the water can pass from the flow to the return pipe. In the second, or return pipe, near the point where it ascends to the ceiling, is placed a rotary pump, or fan wheel, which is always kept in motion. When the openings are all closed between the two pipes, this pump can fan simply the water, but as soon as the return pipe obtains a supply of water from any of the openings between it and the flow pipe, a circulation is established.

The following diagram, resulting from Mr. Anderson's experiments, published in the *Journal of the Institution of Civil Engineers* for 1877, shows the total units of heat given out by convection and wrought-iron pipes per square foot of surface per hour for various differences of temperature applicable either to hot water or steam pipes. Suppose, for example, it is required to know how much heat will be given out by 4 inch cast iron or 3 inch wrought iron pipes at 160° in a temperature of water at 60°, the difference of temperature is 180°, and corresponding to this will be found 2327 units for 4 inch pipes, and 356 units for 3 inch wrought iron pipes per square foot per hour.

The diagram for calculating the heat given out by 4 inch cast iron or 3 inch wrought iron pipes at various differences of temperature. The dotted line shows the heat, and the solid line the surface.

The amount of heating surface to be afforded with hot water pipes depends mainly upon the volume of air to be admitted and removed, and the temperature desired to be maintained, but in any given building there are other circumstances to be taken into account, viz. the position, aspect, material, temperature of locality, thickness of walls, size and form of windows, and other influences affecting the temperature of the incoming air, or causing loss of heat. An empirical rule has been laid down that in a dwelling house 1 square foot of heating surface is required for every 65 cubic feet of space to be warmed, and in a greenhouse 1 square foot for every 34 cubic feet. This empirical rule does not take into account the sanitary considerations which attend the renewal of air.

Steam heated pipes present important advantages in some cases over hot water pipes for heating purposes, because of the higher temperature to which the pipes can be raised, then consequent smaller size, and the facility of conveying the heat to a distance. Steam heating may be applied in every case, and the waste steam from an engine is also applicable for heating.

The direct application of steam heating on a large scale has been made at Lockport, New York. About 200 houses in the city are heated from a central supply through a main of 3 miles of piping, radiating from a boiler house, which contains two boilers 16 feet by 5 feet, and one boiler 8 feet by 8 feet. These boilers are fired through the vents to a pressure of 35 lb to the inch, with a consumption of 1 ton of anthracite coal in twenty-four hours. The water pressure of 35 lb in water and 25 lb in steam is maintained through a total length of 3 miles of piping up to the several points of consumption, where there is a cut off under the control of the consumer. The first 600 feet of the main is 12 inches in diameter. There are 1400 feet of 8 inch pipes, 1600 feet of 3 inch pipes, and 2000 feet of 2 inch pipes. The supply pipes from these mains to the houses are 1 1/2 inches in diameter, and within each house 3/4 inch pipes are used. In addition to the cut off tap from the main under the control of the consumer, there is a pressure valve regulated to a 5 lb pressure under the control of the company, and beyond this is an ingeniously constructed meter, which indicates, not only the total consumption in cubic feet of steam, but also the quantity of steam in each apartment. At each 100 feet of main an expansion valve, like an ordinary piston and socket, is inserted, allowing an expansion in each section of 100 feet of 1 1/2 inches for the heat at 35 lb pressure. No condensation occurs in the mains. They are covered with a thin layer of asbestos paper next the iron, then a wrapping of Russian felt, and finally manilla paper, and the whole is sheathed in tinplate bored out three quarters of an inch larger than the 4 1/2 cent pipes, and laid along the street like gas pipes. The distribution of heat in the apartments is by means of radiators consisting of inch pipes, 80 inches long, placed vertically either in a circle or in a double row, and connected together at top and bottom by horizontal pipes. The condensed water, which escapes at a temperature a little below boiling, and is sufficient for all the domestic purposes of the house, or it may be used as necessary heating power for hot localities and other purposes.

The steam has engine power, and is worked by a steam engine over half a mile from the boilers for motive power, and to a steam engine of 10 horse and 14 horse power is worked from the boilers at a distance of half a mile with but a slightly increased consumption of fuel. The fuel on steam is also used for cooking purposes for boiling, and even for baking. As in the case of gas supply, the steam supply company lay their pipes up to the houses, the consumer paying for all internal pipes, fittings, and radiators. In a small house the steam might cost about 10 cents per hour, amounting to \$150, and in large houses with costlier fixtures to \$500.

Boulton's system of heating with exhaust or waste steam is devised to cause the steam from a steam engine to travel long distances without any back pressure on the engine. It is especially applicable to drying rooms in which 150° Fahr. has been obtained by a large heating surface, for a low temperature less heating surface is required. The capacity of heating by exhaust steam is nearly in a ratio with the fuel expended in the boiler. There is some cooling in passing through the engine, and in the conveyance along the pipes to the rooms to be heated, but this loss is comparatively small if the pipes and the cylinder are covered with a good non-conductor, and the condensed steam is taken back to the boiler. Thus, if the steam be taken from the boiler direct to the pipes at five atmospheres, the temperature would be 307°, and if a comparative capacity of steam was allowed to pass through the engine to create power, and discharge into the pipes, at one atmosphere, it would decrease in temperature to 218°, but it would increase in bulk according to the expansion, and thus to obtain nearly the same temperature in the room the heating surface should be increased.

With an engine of 17 inch cylinder and 25 horse power nominal, the exhaust steam has been made to travel 200 yards in a direct line, as well as to pass into various branches, amounting in the aggregate to about 2300 yards (13 miles) of 1 1/2 inch pipes. After this it warms the water for the boiler, and the steam is not all used up. The whole efficiency of the system depends upon so arranging the pipes as to prevent back pressure. Mr. Boulton assumes that one horse power if properly applied should warm about 80,000 cubic feet of space, subject to reductions for window space, wall space, the number of cubic feet of air allowed to escape for ventilation, and other considerations, and 1/25 down the following empirical rule, viz. 1 square foot of steam pipe is allowed for each 6 square feet of glass in the window, 1 for every 6 cubic feet of air escaping for ventilation per minute, and 1 for every 150 feet of wall, roof, or ceiling, adding about 15 per cent for contingencies.

Wrought iron pipes 1 1/2 inch bore are the most economical for steam, as they afford a large heating surface with small area. In heating living rooms by steam, the high temperature of the pipes affords one of the advantages of steam heating, viz. the direct radiation, and combines with this the advantage which hot water pipes possess of directly warming the air. (D G)

HEBBEL, *FRIEDRICH* (1813–1863), a German poet and dramatist, was born of peasant parents at Wesselburen, in Schleswig-Holstein, 18th March 1813. In his fourteenth year he obtained a humble clerkship in his native parish, but already his ambition was soaring towards higher things. At an early period he began to practise poetical composition, and several of his poems published in the *Modesetzung* at Hamburg awakened such interest that several gentlemen procured him in his twenty-second year the means of preparing himself in Hamburg for the university. He afterwards studied philosophy and history at Heidelberg and Munich. In 1841 he returned to Hamburg, where he published his first tragedy, *Utah*, in a journey which he made to Copenhagen in 1842 he formed the acquaintance of Thorwaldsen and Oehlenschläger, and acquired the more substantial advantage of a travelling annuity from the king of Denmark. He accordingly visited Paris, after which he went to Italy, where he remained several years, staying principally at Rome, Pisa, and Palermo. Having in the spring of 1846 stopped at Vienna on his way home to Germany, he made the acquaintance of the actress Christine Enghaus, whom he married in May of the same year. His marriage led him to take up his permanent residence in Vienna, and probably deepened his interest in dramatic composition, which from that time chiefly occupied his attention. He died in 1863. His principal dramas are *Genoveva*, 1843, *Maria Magdalena*, 1844, *Julia*, 1851, *Agnes Bernauer*, 1855, and *Die Nibelungen*, 1862. They exhibit considerable skill in the portraiture of character, great glow of passion, and a true feeling for dramatic situations, but their poetic effect is marred by frequent extravagances which border on the grotesque, and by the introduction of incidents the unpleasant character of which is not sufficiently relieved. In many of his smaller poems his undoubted poetic gifts found a truer and more artistic utterance.

His collected works appeared at Hamburg in 12 vols. (1855–68). His biography by Emil Kuh was published at Vienna in 1877.

HEBE, in Greek mythology, is a personification of the blooming freshness and youth of nature. Originally she appears almost identical with the pure Greek Aphrodite (as distinguished from the Oriental goddess). Hebe is the daughter of Zeus and Hera, as Aphrodite of Zeus and Dione, but Dione and Hera are only two names of the same goddess. Like Aphrodite, Hebe is called the most beautiful of the gods (*Finl.* *N.* 10, 17). In Sicily and Phlius Hebe is called *Da*, a regular epithet of Aphrodite. In Phlius, where Hebe was worshipped on the citadel in a temple where no image of her was allowed and to which right of asylum was attached, a festival called *ἡεροπόριον* was celebrated to her every year, and ivy was sacred also to Aphrodite. It is in accordance with the close resemblance between Aphrodite and Core that Hebe also has many points of analogy with the latter, to whom she is compared by Gerhard and Welcker (*Gri. Gott.* i. 369). According to the custom for the unmarried daughters of a family, Hebe acts in the Homeric poems as a sort of attendant to the gods and especially to her own mother Hera. She offers the cup to the gods, just as on earth the women, and especially the youngest daughter, did to guests and to warriors departing or returning. She bathes Ares (*Il.* v. 905), as Polyaste does Telemachus. She harnesses the horses for Hera (*Il.* v. 723). She appears very often in connection with the worship of Heia. A statue of her by Naucydes stood beside the Hera of Polyolitus in the Heraeum at Argos. Praxiteles placed statues of her and Athena beside that of Hera in the temple at Mantinea, and Kekule (*Hebe*) maintains that the artistic conception of Hebe which prevailed in the finest period of Greek art

was a slight modification of that of Heia, and he believes that a bust, now in private possession, is the single remaining example of its kind. Welcker's opinion that the so-called Farnese Hebe is really a Hebe has not been generally accepted. In later art she is often represented, like Ganymedes, caressing the eagle, and it is possible that the epithet *Ganymedes*, by which she was called in Phlius, is not really ancient, but arises from the supposed analogy of her office with that of Ganymedes. The meaning of the word Hebe tended to transform into the goddess into a mere personification of the eternal youth that belongs to the gods, and this conception is frequently met with. Then she becomes identical with the Roman *Juventas*, who is simply an abstraction of an attribute of *Jupiter Juventas*, the god of increase and blessing and youth. By a most transparent allegory it was said that *Juventas* and *Terminus* alone of all the gods refused to give away when the temple of *Jupiter Capitolinus* was being built. Perhaps the most interesting point about Hebe is her connexion with *Heraclēs*. When he was received among the gods and reconciled to Heia, Hebe was given him in marriage. This legend appears only in a doubtful line of Homer (*Od.* xi. 608), but Hesiod (*Th.* 950) and Pindar (*N.* 10, 17) also know it. They were worshipped together in the *Cynosarges* at Athens, and represented side by side on the Amyclæan throne. The apotheosis of *Heraclēs* and his marriage with Hebe became a favourite subject with poets and painters. Many instances occur on vases, though several of those enumerated by Kekulé are otherwise explained by other writers on art.

HEBER, *IRVING* (1783–1826), a distinguished prelate and hymn-writer, was born at Malpas in Cheshire in 1783. He early showed remarkable promise, and was entered in November 1800 at Brasenose College, Oxford, where he proved a distinguished student, carrying off prizes for a Latin poem entitled *Carmen Seculare*, an English poem on *Palæstra*, and a prose essay on *The Sense of Honour*. In November 1804 he was elected a fellow of All Souls College, and, after finishing his distinguished university career, he made a long tour on the Continent. He was admitted to holy orders in 1807, and was then presented to the family living of Hodnet in Shropshire. In 1809 Heber married Amelia, daughter of St Shopley, dean of St Asaph. He was appointed Hampton lectures for 1816, preaching at St Asaph in 1817, preacher at Llandovery in 1822, and bishop of Calcutta in March 1823. Before sailing for India he received the degree of D.D. from the university of Oxford. In India Bishop Heber laboured indefatigably, not only for the good of his own diocese, but for the spread of Christianity throughout the East. Animated by apostolic zeal, he undertook numerous tours in India, consecrating churches, founding schools, and discharging other Christian duties. Such devotion to his work in a trying climate told severely on his health. At Trichinopoly he was seized with an apoplectic fit when in his bath, and expired on 23 April 1826.

Heber was a man of profound learning, refined literary taste, and great practical energy. His Christian character manifested all the beauty and simplicity of the days of the early church. As a poet he has attained a high place. His *Palæstra* is generally considered the best prize poem ever written at Oxford. Heber's fame rests mainly on his hymns, which, as literary compositions, rank among the best in the English language. Those beginning as follows may be instanced—"Lord of mercy and of might," "Brightest and best of the sons of the morning," "By good Sileas's shady rill," "God, that madest earth and heaven," "The Lord of might from Sinai's brow," "Holy, holy, holy, Lord God Almighty," "From Gilead's land's icy mountains." "The Lord will come, the earth

shall quiko", "The Sea of God goes forth to war!" Hebrew hymns and other poems are distinguished by richness of style, pathos, and soaring aspiration, but they lack of originality, and are rather rhetorical than poetical in the strict sense.

Hébert was a voluminous author, as may be seen from the following works: — *Préface*, 10 pages, to which is added the *Passage of the Red Sea*, 1800; *Épique*, *Discours sur le Présent*, 1800; *The Personality and Office of the Christian Church*, translated and corrected, being the *Discours de l'Église* for 1815; *The Whole Works of Bishop Jeremy Taylor*, with a *Life of the Author*, and a *Critical Examination of his Writings*, 1822; *Hymns written and adapted to the Weekly Church Service of the 1st year, principally by Bishop Heber*, 1827; *A Journey through India*, 1830; *Sermons preached in England*, and *Sermons preached in India*, 1820; *Practical Sermons*, 1837.

For further information about Hébert see his *Life*, by his widow, 1870, which contains a number of Hébert's magnificent writings. — *The Last Days of Bishop Heber*, by Thomas J. Dolan, 100 Mulhouse of Malvern, 1880, and *Monographs of a Great Man*, by W. G. Smith, 1881.

HEBERDEN, WILLIAM (1710-1801), a practical physician of some celebrity, was born in London in the year 1710. In the end of 1724 he was sent to St John's College, Cambridge, where he obtained a fellowship about 1730, became master of arts in 1732, and took his degree in physic in 1739. He remained at Cambridge about ten years longer as a practitioner of physic, and gave an annual course of lectures on materia medica. In 1746 he became a fellow of the Royal College of Physicians in London, and two years afterwards he left Cambridge to establish himself in London, where he was elected a fellow of the Royal Society in 1769, and was employed in a very extensive medical practice for more than thirty years. Latterly he passed his summers at a house which he had taken at Wimbor, but he continued his practice during the winter for some years longer. In 1778 he was made an honorary member of the Royal Society of Medicine at Paris. He died 17th May 1801.

Heberden's first publication seems to have been a short essay on the incongruous disposition of the multitude and their, entitled *Antichines* (1746). He also wrote several papers for the Royal Society, which were published in its *Transactions*, and he was one of the principal contributors to the first three volumes of the *Medical Transactions*, published in a great measure at his suggestion, by the College of Physicians. He is, however, best known by his *Conjectures on the History and Cause of Diabetes*, the result of careful notes made in his pocket-book at the bedside of his patients. In accordance with his directions the work was published posthumously in 1802, prefixed to it is a short notice of his life.

HEBERT, JACQUES HENRI (1755-1794), a French revolutionist, nicknamed from the newspaper he edited "Le Père Duchesne," was born of obscure parents at Alençon in 1755. He came at an early age to Paris, where he lost more than one situation through malversation, and was in abject poverty when the occurrence of the French Revolution opened up to him a career in which he obtained considerable temporary success and permanent notoriety. Having shown great readiness and proficiency in a style of writing and of oratory which appealed to the worst feelings of the revolutionary mob, he soon acquired great influence in the clubs, and was chosen to oppose the constitutional paper *Le Père Duchesne* by editing a revolutionary paper of the same name. The scurrilous and extravagant language of the new print exactly coincided with the sentiments of the class to whom it was addressed, and it contributed not a little to several of the worst and most violent manifestations of the revolutionary spirit. It had a very beneficial influence on the fortunes of its editor, who after the 10th August 1793 was one of the chief members of the revolutionary commune, and on the 24 September was appointed substitute to the *procureur syndic*. On the 24th May 1793 an order was sent out for his arrest by the more moderate party of the commune on the ground that he was plotting their assassination, but on account of a formidable outbreak of the mob he was set at liberty,

and when he appeared again at the commune he was presented with a civic crown. Having been appointed a member of the commission to examine Marie Antoinette, he with unexampled moral baseness falsely accused her of a crime too scandalous to be mentioned. Along with several of his colleagues he invented the worship of the goddess "Reason," and subsequently he organized a party of ultra-revolutionists known as the Hébertists or *enragés*. The faction were, however, arrested by the committee of public safety, and on the 24th March 1794 were led forth to execution. Hébert behaved with great cowardice at his trial, and died amid the jeers and insults of the mob over whose passions he had at one time exercised such sway and to whom he owed his promotion to power.

He was the author of *Épître adressée par le club de la Père Duchesne*, 1791; *Le père du Père Duchesne*, 1790; *Le club de la Père Duchesne*, 1791; *Nouvelle lettre au magne*, 1792.

HEBREW LANGUAGE AND LITERATURE The name *Hebrew* (Latin, *Hebraeus*, Greek, ἑβραῖος) is a transcription of 'ebrydā, the Aramaic equivalent of the original Old Testament word עִבְרִי, 'ebri, pl. 'ebriim, which is the proper Gentile name of the people who also bore the collective name of Israel or Children of Israel (B'né Isra'el). The name of Israel with its sacred associations in the patriarchal history is that by which the Old Testament writers prefer to designate their nation, and this circumstance, combined with the fact that the Sacred Text frequently employs the term Hebrews whose foreigners are introduced as speaking or spoken to (e.g., Exod. ii 6, 1 Sam. ix 6, Gen. xi 15, Ex. iii 18), has led to the conjecture that the name of Hebrews (men from the other side, *ad* of the Euphrates) was originally given to the descendants of Abraham by their Canaanite neighbours, and continued to be the usual designation of the Israelites among foreigners, just as the Magyars are known to other Europeans as Hungarians (foreigners), as we call the High Germans (Germans), or as the Greeks gave the name of Phoenicians to the people that called themselves Canaanites.¹ A closer view of the case does not confirm this conjecture. The name of Israel is often found in the Old Testament in the mouth of foreigners, and the whole *usus loquendi* is explained by the observation that the Gentile name corresponding to the collective "Israel" is regularly "Hebrew" and not "Israelite," the latter word being rare and apparently of late formation.² Nor has the word Hebrew been hitherto found in the early monuments of other Eastern nations, for the identification proposed by Chabas which finds the Hebrews in the hieroglyphic Apurim is more than doubtful.³ On the other hand the name of Israel appears on the stone of Mesha king of Moab, and perhaps has been deciphered on Assyrian monuments.⁴

The form 'ebri, in the language of Semitic grammarians, a relative noun, presupposing the word 'Eber as the name of the tribe, place, or common ancestor, from whom the Hebrews are designated. Accordingly we find Eber as a nation side by side with Assyria in the obscure poetical passage Num. xxi 24, and Eber as ancestor of the Hebrews in the genealogical lists of Gen. x, xi. Here we must apparently distinguish two records.⁵ According to

¹ See especially Gesenius, *Geschichte der Hebräischen Sprache und Schrift*, pp. 9 seq., most recently Kautzsch in Rehm's *Handwörterbuch*.

² In 3 Sam. xvi 9 Israelite must be connected to Ishmaelite, as in the parallel passage 1 Chron. i 17.

³ Chabas, *Mémoires Egyptologiques*, i. 42; Ebers, *Ägypten und die Ägypter*, i. 816; Budge, *Bay, Geschichte Ägyptens*, 188 (Eng. trans., i. 128-9); Birch, *Byzant*, p. 128.

⁴ Schaefer, *Kanaanäische und Aramäische Inschriften* (Gießen, 1878), pp. 369, 386, gives the latest arguments for this not undisputed reading.

⁵ See De Goeje on the *Theol. Tijdschrift*, 1870, p. 243, and Wellhausen in *Jahrbuch f. D. Theol.*, 1876, p. 385.

Gen. xi (and Gen. x 24) Eber is the great-grandson of Shem through Arphaxad, and ancestor of Terah through Peleg, Reu, Serug, and Nahor. These are not to be taken as the names of individual men. Several of them are designations of places or districts near the upper waters of the Euphrates and Tigris, and among other circumstances the place at the head of the series assigned to the district of Airapachitis (Alphaxad), through which a migration from Ararat to the lands occupied by the Semites in historical times would first pass, suggests the probability that the genealogy is not even meant to exhibit a table of ethnological affinities, but rather presents a geographical sketch of the early movements of the Hebrews, who are personified under the name of Eber. This is so we can hardly venture to assert (with some scholars) that the author of the list (the Levitical Elohist) extended the name of Hebrews to all descendants of Terah.¹ The case is different with another and apparently older record of which a fragment seems to be preserved in Gen. x 21, 25-30. Here there is no intermediate link between Shem and Eber. Sons of Shem and sons of Eber appear to be coextensive ideas, and to the latter are reckoned not only the descendants of Peleg (Assamians, Israelites, Ishmaelites, etc.), but the South Arabian tribes of Joktan. We possess no information which casts light on this wide conception of the sons of Eber, and in the ordinary language of the Old Testament Hebrew and Israelite are strictly synonymous.

Compere, however, in his interesting conjectures, *Atlas Géographique Arabique* (Paris, 1876), p. 294, who identifies Peleg with Euphrat in Central Arabia, and finds in the record a witness to the truth of the view that Arabia is the original center of the Semitic dispersion, a view which is shared by other scholars, as Huet (*Archéologie Israélite*, pp. 20, 89), and Schaefer (*S. D. M. G.*, 1878, pp. 897-124). In this connection it is perhaps worth while to note that the gens Gentilis name Obar, belonging to Obar, a minor division of the Joktanite tribe of the *Adi* (*Arabian Index*, ed. Voth, p. 376).

When it is recognized that Eber in Genesis is not an actual personage but an ethnological or geographical abstraction, we are thrown back on etymological conjectures as to the origin of the name of Hebrews. Eber means the further bank of a river, from a root meaning to cross. Hence in Gen. xiv 13 the Septuagint renders Abram the Hebrew by $\delta \nu\epsilon\pi\epsilon\rho\alpha\varsigma$, "the crosser."² Grammatically more accurate, while resting on the same etymology, is the rendering of Aquila, $\delta \nu\epsilon\pi\alpha\rho\tau\eta\varsigma$, "the man from the other side" of the Euphrates, which is the explanation of Jewish tradition (*B. Shab. Rabba*, and Raab) and still generally adopted. It is, however, far from satisfactory, and almost of necessity depends on the theory that the name was fixed upon the Hebrew immigrants by the earlier inhabitants of Canaan.³ A modified form of the etymology takes Eber in the Arabic sense of a river bank, and makes the Hebrews "dwellers in a land of rivers" (Steiner in the *Bibel-Lex.*, i. 613). This goes well with Peleg (watercourse), as in Arabia we have the distinct Peleg, so named because it is furrowed by waters (Sprenger, *Geog. Arab.*, p. 234).⁴

The name *Hebrew Language*—By the Hebrew language we understand the ancient tongue of the Hebrews in Canaan—the language in which the Old Testament is composed, with the exception of the Aramaean passages (Jer. x 11, Ezra iv 8-vi 18, vii 12-26, Dan ii 4-vii 28). But

we do not find that this language was called Hebrew by those who spoke it. It is the *lqy*, $\epsilon \epsilon$, speech of *Canaan*, Isa. xiv 18, or, as spoken in Southern Palestine, *lqyry Yemah* (2 Kings xviii 26, Neh. xiii 21). The later Jews call it the *holy tongue* in contrast to the *profane* Aramaean dialect (commonly though improperly enough called Syro-Chaldaic) which long before the time of Christ had superseded the old language as the vernacular of the Jews. This change had already taken place at the time when the expression "in Hebrew" (בְּחִיבְרִי) first occurs (Pologus to Suach), and both in the Apocrypha and in the New Testament the ambiguous term, naming the language after those who used it, often denotes the contemporary vernacular, not the obsolete idiom of the Old Testament. But the other sense was admissible (*q. d.* Rev. x 11, and so frequently in Josephus), and naturally became the prevalent one among Christian writers who had little occasion to speak of anything but the Old Testament Hebrew.⁵ In modern usage it is incorrect to call the Jewish Aramaean Hebrew, though uneducated Jews apply the name even to the corrupt German and Spanish jargons which they are accustomed to write and print in Hebrew characters.

Character and Philological Relations of Hebrew—Hebrew is a language of the group which since Eichenhorn has generally been known as Semitic, and of which Arabic and Ethiopic (Southern Semitic), the various dialects of Aramaean, and the language of the Assyrian and Babylonian cuneiform inscriptions are the other chief representatives. From its geographical position as the language of Palestine between the Aramaeans of the north and the Arabs of the south, Hebrew has been called Middle Semitic. Or Aramaean Assyrian and Hebrew may be grouped together as Northern Semitic in contrast to Arabic and Ethiopic. The affinities of the Semitic languages are so close that they may fairly be compared with a sub group of the Indo Germanic family—for example, with the Teutonic languages. The fundamental unity of the Semitic vocabulary is easily observed from the absence of compounds (except in proper names) and from the fact that almost all words are derived from their roots in definite patterns (*maṣnūn*) as regular as those of grammatical inflexion. The roots regularly consist of three consonants (seldom four or five), the accompanying vowels having no radical value, but shifting according to grammatical rules to express various embodiments of the root idea. The trilateral roots are substantially common to the whole Semitic group, subject to certain consonantal permutations, of which the most important are strikingly analogous to those laid down by Grimm for the Teutonic languages.

There are four sounds in Arabic unknown to Hebrew and Aramaean, and for which the former regularly has a substitute, the letter אֵלֶּם —in one case a deep guttural. This guttural (אֵלֶּם), and the palatal letters which in the following table are represented by א, ה, י , are peculiar Semitic sounds.

Arabic		Hebrew		Aramaean
אֵלֶּם	—	אֵלֶּם	—	אֵלֶּם
אֵלֶּם	—	אֵלֶּם	—	אֵלֶּם
אֵלֶּם	—	אֵלֶּם	—	אֵלֶּם
אֵלֶּם	—	אֵלֶּם	—	אֵלֶּם

On the last equation see Lagarde, *Semitaica*, i. 22, Noldike in *S. D. M. G.*, xxxi, 405, and on the permutation of consonants in general, *Hebr. Gram. Syn.*, § 24, Stade in *Monatss. für bibl. Theol.* (1876), p. 179 *seq.* Whether the Arabic or Aramaean form are the older is disputed. No one maintains that the Hebrew forms are original.

¹ The term "Hebrew language" seems to have originated with the Greeks or Hellenists. Philo, however, calls the language of the Old Testament Chaldean (*De Vita Mos.*, i. 5, 6, *q. d.* Jerome on Dan. 1). On the use of the expression "Hebrew language" in the Talmud, see Berliner, *Beiträge zur heb. Gr.* (Berlin, 1878), p. 5.

¹ The Targumists, according to other testimonies, are Aramaeans (Gen. xxi. 20 *seq.*, Deut. xcvi. 5), but our Elohist, who can hardly have written before the captivity, makes Aram a separate offshoot of Shem, having nothing to do with Eber (Gen. x. 25, 28).

² Compare Jerome, *Quaest. Heb.* on the passage, and Theodoret, *Qu. LXXI. in Gen.*

³ Compere Ewald, *Hebr. Isr. Ind.* (8d. ed.), i. 407 *seq.* (Eng. trans., i. 284). When also other etymologies are noticed.

⁴ Complete ignorance of Hebrew made it possible for early Christian writers to derive the name of the Hebrews from Abraham. See Eichenhorn's *Phatag.*, hb. ii, cap. 14. Other guesses will be found in the *Onomasticon*.

Derivation from the roots and inflexion proceed partly by the reduplication of root letters and the addition of certain preformatives and afformatives (more rarely by the insertion of formative consonants in the body of the root), partly by modifications of the vowels with which the radicals are pronounced. Almost every root expresses in its origin something that can be grasped by the senses, and the mechanism by which words are formed from the root is adapted to present sensible notions in a variety of *anances*, and in all possible embodiments and connexions, so that there are a regular forms to express in a single word the intensity, the repetition, the production of the root-idea—the place, the instrument, the time of the occurrence, and so forth. Thus the expression of intellectual ideas is necessarily metaphorical almost every word being capable of a material sense or at least conveying the distinct suggestion of some sensible notion. For example, the names of passion depict their physiological expression, “to confer honour” means also “to make heavy,” and so on. The same concrete character, the same inadequacy to convey purely abstract thoughts without a substratum appealing to the senses, appears in the grammatical structure of the Semitic tongues,—for example, in the absence of the neuter gender, in the extreme paucity of particles, in the scanty provision for the subordination of propositions, which deprives the Semitic style of all involut periods and reduces it to a succession of short sentences linked by the simple copula *and*. The fundamental element of these languages is the noun, and in the fundamental type of sentence the predicate is a noun set down without any copula and therefore without distinction of past, present, or future time. The finite verb is developed from nominal forms (participial or infinitive), and is equally without distinction of time. Instead of tenses we find two forms, the perfect and the imperfect, which are used according as the speaker contemplates the verbal action as a thing complete or as conditional, imperfect, or in process. It lies in the nature of this distinction that the imperfect alone has mood. In their later stages the languages seek to supply the lack of tenses by circumlocutions with a substantive verb and participles. Other notable features common to the Semitic tongues are the use of appended suffixes to denote the possessive pronouns with a substantive, or the accusative of a personal pronoun with a verb, and the expression of the genitive relation by what is called construction or annexation, the governing noun being placed immediately before the genitive, and if possible slightly shortened in pronunciation so that the two words may run together as one idea. A characteristic of the later stages of the languages is the resolution of this relation into a prepositional clause.

These and other peculiarities are sufficient to establish the original unity of the group, and entitle us to postulate an original language from which all the Semitic dialects have sprung. Of the relation of this language to other linguistic stems, especially to the Indo-Germanic on the east and the North-African languages on the west, we cannot yet speak with certainty, but it appears that the present system of triliteral roots has grown out of an earlier biliteral system which, so far as it can be reconstructed, must form the basis of scientific inquiry into the ultimate affinities of the Semitic group.¹

Before the use of comparative philology it was a familiar opinion that Hebrew is the original speech of mankind taken from the Jews, and as already expressed in the Palestinian Targum on Gen. xi. 1, this opinion drew its

main support from etymologies and other data in the earlier chapters of Genesis, which, however, were as plausibly tainted by Syriac writers in favour of their own tongue.² Till quite recently many excellent scholars (including Ewald) have claimed for Hebrew the greatest relative antiquity among Semitic tongues. But though Hebrew has by far the oldest literature, this does not prove that its structure comes nearest to the original Semitic language. And it is now generally recognized that in grammatical structure the Arabic, shut up within its native deserts till the epoch of Islam, preserved much more of the original Semitic forms than either Hebrew or Aramaic. In its richer vocabulary, in the possession of distinct cases and moods, in the use for feminine nouns of the afformative *t*, which in the northern dialect has passed through *h* (originally audible as in Egyptian Arabic) into a mere vowel, in the more extensive range of passive and modal forms, and in other refinements of inflexion, Arabic represents no later development, but the original wealth and primitive subtlety of Semitic speech, as appears not only from fragmentary survivals in the other dialects but from an examination of the process of decay which has brought the spoken Arabic of the present day into a grammatical condition closely parallel to the Old Testament Hebrew. But while Arabic is in many respects the older brother, it is not the parent of Hebrew. Aramaic, the eldest member of the group had an independent development from a stage prior to any existing language, though it would seem that Hebrew did not branch off from Aramaic so soon as from Arabic, while in its later stages it came under direct Aramaic influence.

Among the points in which Hebrew differs both from Arabic and Aramaic may be mentioned the consonantal claims already spoken of, the system of long vowels, the use of *Waw* consecutive, the *h* of the causative and intensive stems and of the article, and the compensation for omitting the reduplication of gutturals and *r* by lengthening a preceding vowel.³ Again, Hebrew agrees with Aramaic against Aramaic in possessing a prefixed article, in the use of the *Nihil* (Arab. *ya*), and in other minor points. But in more notable features Hebrew and Aramaic agree against Arabic, as in the absence of broken plurals, the place of the accent, the aspiration of certain letters whenever they are preceded by a vowel sound, and the substitution of *y* for *w* on the final radical of roots. To give further details would carry us too far into comparative grammar. Speaking generally, it may be said that Hebrew is less copious in vocabulary than Arabic (in which tongue, however, the abundance of synonyms is largely due to an artificial compound of several dialects), and less rich in subtle distinctions of grammatical form and refinements of syntax. On the other hand, Hebrew is much superior to Aramaic in flexibility of structure, in fulness of vowels, and in all the qualities which adapt a language for poetical expression.

Geographical Sphere and History of Hebrew as a Spoken Language.—The Hebrew spoken by the Israelites in Canaan was separated only by very minor differences (like those of our provincial dialects) from the speech of neighbouring tribes. We know this for the Moabite language from the stone of Mesha, and the indications furnished by proper names, as well as the acknowledged affinity of Israel with these tribes, make the same thing probable for Ammon and Edom. More remarkable is the fact that the Phoenicians and Canaanites, with whom the Israelites acknowledged no brotherhood, spoke a language which, at

¹ Theodor, *Quest. vs. Gen.*, v. 1, Barthelemy, and others cited by Assmann, *Bib. Or.*, in 314. The same opinion appears among the Babylonian Jews (Rab. in *Syn.*, 85b). Conversely, Jacob of Serugh considers the priority of Hebrew (see *J. P. M. G.*, xvi., p. 330). The Arabs, whose language is in many points older than either, yield priority to Hebrew (Abulafia, *H. J.*, p. 18), or to Syriac (Tabari, i., 320). Abu Has in Abulafia, p. 148, the language of the race to which they owed their first knowledge of the Hebrew language.

² The verbal prefixes *ha*, *hith*, appear in Palestinian Aramaic, and the Aramaic dialects also exhibit some traces of a lengthened vowel before *r* (Nöldeke, *Mosad. Gram.*, p. 17). On the other hand, the transcription of the LXX. shows that Hebrew once could double *r*.

³ Renan, *Histoire des Langues Semitiques*, sketches the history of research in this direction. Noteworthy are the remarks of Lagarde, *Synactica*, p. 121. On survivals from the biliteral stage, see Nöldeke, *Mosadische Gram.*, p. 98.

least as written, differs but little from Biblical Hebrew. This observation has been used in support of the very old idea that the Hebrews originally spoke Aramaic, and changed their language in Canaan. But an extant study of the Phœnician inscriptions shows differences from Hebrew which suffice to constitute a distinct dialect, and combine with other indications to favour the view that the descendants of Abraham brought their Hebrew idiom with them from Haman. And in this connexion it is important to observe that the old Assyrian, which preceded Aramaic in regions with which the book of Genesis connects the origins of Abraham, is in many respects closely akin to Hebrew.¹ As the origin of Hebrew is lost in the obscurity that hangs over the early movements of the Semitic tribes, so we know very little of the changes which the language underwent in Canaan. The existence of local differences of speech is proved by Judges xii 6, but the attempt to make out in the Old Testament records a northern and a Judæan dialect, or even besides these a third dialect for the Samaritans of the extreme south,² has led to no certain results. In general it may be said that the Biblical text supplies inadequate data for studying the history of the language. Semitic writing, especially a purely consonantal text such as the Old Testament originally was, gives an imperfect picture of the very grammatical and phonetic details most likely to have been lost in the course of time. The late punctuation (including the notation of vowels), and even many things in the present consonantal text, represent the formal pronunciation of the Synagogue as it took shape after Hebrew became a dead language—for even the Septuagint has often a more primitive pronunciation of proper nouns. This modern system being applied to all parts of the Old Testament alike, many archaisms were obliterated or disguised, and the earlier and later writings present in the received text a grammatical uniformity which is certainly not original. It is true that occasional consonantal forms inconsistent with the accompanying vowels have survived—especially in the books least read by the Jews—and appear in the light of comparative grammar as indications of more primitive forms. These sporadic survivals show that the correction of obsolete forms was not carried through with perfect consistency, but we are never safe to argue as if we possessed the original form of the texts.

In the Pentateuch, for example, the form מִן (from) is not only for מִן (3d personal pron. masc) but for מִן (the feminine). And hence a favourite argument was drawn for the superior antiquity of this part of the Old Testament, the same being in force elsewhere (Fenold's *Mass Ivrit*, p. 233), especially in Babylonian copies of the prophets (Gugler, *Urschrift*, p. 236; *J. D. M. G.*, xxvii 676). The feminine can never by any possibility have been pronounced as he, but the old orthography was probably מִן for he and he-like (Nöldeke in *Bibel Lexikon*, at *ayra*, after Levy).

The chief historical changes in the Hebrew language which we can still trace are due to Aramaic influence. The Northern Israelites were in immediate contact with Aramaean populations and some Aramaic loan-words were used, at least in Northern Israel, from a very early date. At the time of Hezekiah Aramaic seems to have been the usual language of diplomacy spoken by the statesmen of Judah and Assyria alike (2 Kings xviii 26). After the fall of Samaria the Hebrew population of Northern Israel was partly deported, their place being taken by new colonists most of whom probably had Aramaic as their mother-tongue. It is not therefore surprising that even in the language of Judæa interesting signs of Aramaic influence

appear before the Exile.³ The fall of the Jewish kingdom accelerated the decay of Hebrew as a spoken language. Not indeed that the captives forgot their own tongue in Babylon, as older scholars supposed on the basis of Jewish tradition. The Exilic and post-Exilic prophets do not write in a lifeless tongue, and Hebrew was still the language of Jerusalem in the time of Nehemiah (ח' ג' in the middle of the 5th century B.C.). But after the Exile the petty people of the Jews were in daily intercourse with a surrounding Aramaean population, and the Aramaic tongue, which was the official language of the western provinces of the Persian empire, began to take rank as the recognized medium of polite intercourse and letters even among tribes of Asiatic blood—the Nabataean whose inscriptions in the Hauran are written in Aramaic. Thus Hebrew as a spoken language gradually yielded to its more powerful neighbour, and the style of the latest Old Testament writers is not only full of Aramaic words and forms but largely coloured with Aramaic idioms, while their Hebrew has lost the force and freedom of a living tongue (Ecclesiastes, Esther, some Psalms, Daniel). The Chionides no longer thoroughly understood the Old Hebrew sources from which he worked, while for the latest part of his history he used a Jewish Aramaic document, part of which he incorporated in the book of Ezra. Long before the time of Christ Hebrew was the exclusive property of scholars, and its further history is that of a merely literary language.

The Literary Development of Hebrew.⁴—The Semitic peoples possessed the art of writing and an alphabetical character from a date so remote as to be lost in the mists of antiquity. This character was formerly known as Phœnician, its invention being ascribed to that people (Tac, *Ann.*, xi 14). In reality it was the common property of all Semitic nations between Assyria and Egypt—an alphabetic character in contact on the east and on the west with more complicated syllabic or hieroglyphic systems, from one or other of which it may possibly have been derived.

De Rouge's theory that the alphabet was derived by the Phœnicians from the Egyptian hieratic writing obtained much currency a few years ago (see ALPHABET), but has rather lost ground since the appearance in 1874 of the long expected *Mémoires sur l'origine Égyptienne de l'Alphabet Phœnicien*. See the criticism in Lepsius's *Egyptische Grammatik*, p. 115 seq. A newer theory by Decker (*J. D. M. G.*, xxvi 102 seq.) derives the alphabet from the cuneiform character, and makes the Aramaean its authors, for which there is ancient tradition in Pliny, Diodorus, and Eusebius Alexandrinus. Decker dates the invention from the 9th century B.C., when the Assyrians first established themselves in Asia. This is certainly wrong, for, apart from other arguments, the stone of Melis is not a product of the first days of alphabetic writing. Against the derivation of the Semitic alphabet from any hieroglyphic system, see Levy, *Phœnicische Studien*, i 49 seq. The best comparative table of Semitic alphabets is that by Euting in the English translation of Bickell's *Ursprung der Hebr. Gram.* (Leipzig, 1877). On the history of Hebrew writing, especially in its bearing on the history of the Biblical text, see Wellhausen in Bickell's *Einleitung*, 4th ed (1878), with Nöldeke's remarks, *J. D. M. G.*, xxxv 661 seq.

This ancient alphabet consists of twenty-two consonants, of which one at least (p) stood in Hebrew for two distinct sounds, still separated in the Septuagint pronunciation. The vowels were supplied by the reader—which is not so difficult in Semitic languages, where vocalization constitutes no difference of root. In certain cases the weaker consonants served as *matres lectionis* to indicate cognate vowel sounds and preclude ambiguity of pronunciation, but in the old

¹ See Stade's essay on the relation of Phœnician and Hebrew, *Monatsschriftliche Forschungen* (1875), with Nöldeke's criticism, *J. D. M. G.*, xxix 336, also the latter's article, "Sprache, hebr. u. semit.", in *Bibel Lexikon*, at 349.

⁴ An argument to the contrary drawn by Jewish interpreters from Neh. viii 1 rests on false exegesis.

⁵ As we possess no books in classical Hebrew except the Old Testament, the reader is referred for several examples of this topic to the sketch of the Old Testament literature in the article BIBLE.

writing this usage was far less extensive than in our Hebrew MSS's, and hardly applied except to diphthongs and to a — at the end of words.¹ This old character with its scanty indications of vowels continued to be used by the Hebrews throughout the flourishing period of their literature and for some time after the Exile, till at length they gradually adopted a newer form of letters (the square or, as the Talmud calls it, the Assyrian character) which was developed among the Samaritans and spread with the increase of Aramaic influence. Jewish tradition ascribes the introduction of the square character to Ezra (*Synh* 21b 23a, Jerome, *Prod. Gid.*), but the Samaritans, who did not receive the Pentateuch from the Jews till about 400 B.C., must have got it in the old letter which they still retain in a corrupted form. The square letter probably did not prevail till a good deal later, the earliest mention in which it appears being of the date 176 B.C. (published by De Vogue, *Rev. Arch.* 1864), while the coins of Judaea retain the old character still later. The transformation was complete before the time of Christ, for Mat. v. 16 alludes to the new form of *Yod* (yot).² By this time too the use of *matres lectionis* must have become more ample. The later introduction of vowel points and accents belongs to the history of the study of Hebrew as a dead language. The forms of the old Semitic alphabet are most suitable to be cut on stone, and indicate a special adaptation for monumental inscriptions (cf. the two tables of the Decalogue). Between the beginning of such inscriptions and the general use of writing for literary purposes, a considerable period might intervene. The earliest products of Hebrew authorship seem to have been lyrics and laws, which would circulate in the first instance from mouth to mouth without the use of written copies. We have notices of only written collections of lyrics prior to our present historical books—the *Book of the Wars of Jehovah* (Num. xxi. 14) and the *Book of Joshua* (Josh. x, 2 Sam. i). We have no clue to the age of the former book, but the lines quoted from it are plainly of great antiquity. The *Book of Joshua* is not earlier than the time of Solomon, for a fragment from it referring to the building of the temple has been recovered from the Septuagint of 1 Kings viii (Wellhausen in Black, *ut supra*, p. 236). The earliest date of written law books is uncertain. It may fairly be made a question whether Moses left in writing any other laws than the commandments on the tables of stone. Even Ex. xxiv. 4 and xxvii. 27 may in the original context have referred to the ten words alone. And it is certain that ancient law was handed down by oral tradition and local custom to a much later date. The prophets frequently allude to the oral decisions of the priests as a source of law, and the practice of appealing to the local customs of certain towns is alluded to in 2 Sam. x. 18 (as restored by Ewald from the LXX)—“As at Abel and at Dan whether thy genuine old statutes of Israel have lost their force.” In like manner the story of the early fortunes of the nation down to the time of David often presents characteristics which point to oral tradition as its original source. Yet written history began comparatively early. A scribe was attached to the royal court from the reign of David downwards, and the older parts of the books of Samuel, which must have been written not long after the time of that king (see

David), are framed in a masterly style, which shows that the art of composition in prose was already thoroughly understood. So too the best written and most brilliant part of the narrative of the Pentateuch—the combined history of the Jehovah and the non-Levitical Elohist—appears to be unquestionably earlier than the use of prophetic literature in the 8th century B.C. In this narrative itself the product of more than one writer—as are included several collections of old laws, so that we have between the time of David and the age of Amos and Hosea a flourishing historical and legal literature, in which and in lyrical collections like the *Book of Joshua* were embodied many poems, legends, and other remains, transmitted whether orally or by writing, from a much earlier date. To the same period may be assigned the most interesting and graphic histories in the book of Kings, the splendid episode of Elijah, and other remains of Ephraimite history, and to these must probably be added the main stock of the Song of Solomon, though this lyric drama has suffered much from interpolation, and presumably was not written down till a comparatively late date and from imperfect recollection, so that its original shape is very much lost. It is mainly from the admirable prose narratives, to which nothing in later books can be compared, that we must judge of the first bloom of Hebrew literature under the ancient kingdoms of Judah and Ephraim, before the circumstances that accompanied the advance of Assyria and prior to the influence of written prophecy. It is a literature eminently fresh and vivacious, full of exact observation of nature and of men, always drawing directly from life, and working on the reader not by elaborate description but by dramatic presentation of character and action. The authors are too intent upon the story to interpose their own comments or point a moral, but they tell their tale with sympathy and often with an undercurrent of dry humour. It can hardly be said that the writings of this period have a specifically religious purpose. Reflecting with admirable veracity the actual life of the nation they are full of the relation between Israel and Jehovah, because that relation was constantly present to the people as a very real fact without which the history could not be told. It is to this circumstance that we owe the preservation of so huge a mass of early prose, which was taken over and incorporated in their works by later historians who wrote with a distinctly religious purpose, while on the other hand the early lyric collections have disappeared, all but a few fragments, presumably because their tone was prevailingly secular. That the Hebrews once possessed a poetry of high merit drawn from the themes of ordinary life appears, not only from the book of Canticles and such relics as the Song of the Well (Num. xxi. 17, 18), but from the names of popular songs preserved in the titles of the Psalms. Thus we learn from Isa. lvi. 8 that the title *Al-Tashchut* (*Fe Iva*) is taken from a vintage song of which the first line was “Destroy it not, for a blessing is in it.” These popular songs, then, survived the Exile and long continued to live in the mouths of the people. But they were without interest to the later guardians of Israel's literature, and fell into oblivion when Hebrew ceased to be the vernacular of the nation. A last echo of the festival songs of the Jewish maidens in the Talmud (*Mishna Ta'anit*, iv. 8, and the corresponding Gemara) shows only the total decay of the popular muse.

In this earliest period—the age of popular literature, as we may call it, modelled upon the songs and histories that circulated orally through the country—there is a remarkable preponderance of writings connected with the northern kingdom, and these include the narratives that are fullest of human interest and the poetry richest in colour and imagination, such as the loves of Jacob and Rachel, the history of Joseph, the life of Elijah, the pictures of nature

¹ The stone of Moab is the earliest example. Lagarde, *Orisch. Debut* 2, *Præfation* (1868), p. 4, observed that the LXX translated from a Hebrew copy without *matres lectionis*. This is put rather too fully, but in very many cases (cf. compare Wellhausen, *ut supra*, viii. 1, *cf. de BB. Sanhedrin* (1871), *Niddah*, *p. f. Werschk.* *Theol.* (1873), p. 120, Chwolson in *Travaux de la 8^{me} session du Congrès international des Orientalistes*, pt. ii).

² A papyrus of the 13th century B.C., showing the square letter as it was written in Egypt a little before the time of Christ, has been examined by the Palaeographical Society (*Or. Ser.*, 1877).

in the Canticles. The political and social superiority of Ephraim before the conflict with Assyria is reflected in the literature. A new epoch begins with the rise of written prophecy in the 8th century. By this time writing and literary knowledge were widely diffused (Isa viii 1, xxx 8, x 19).¹ Amos, himself an excellent stylist, in whose book only perverse ingenuity can trace marks of rusticity ('impetuous sermons,' says Jerome), was a simple herdman in the wilderness of Judah. Yet it appears that the origin of written prophecy was due less to the spread of education than to the rise of a new school of men whose whole method and aims were in conflict with the official prophetic societies, the unworthy successors of Samuel and Elijah.

In the terrible struggle with Nineveh, when the kingdom of Ephraim perished and Judah seemed lost beyond hope, the new prophecy, clear of vision when all were blinded, calm in its unshaken faith of ultimate victory, and pursuing with unflinching steadfastness a great purpose of righteousness, established a spiritual and intellectual ascendancy which is stamped on the whole literature of the Assyrian and Chaldean periods. In the book of Deuteronomy the ancient ordinances of Israel were rewritten in the prophetic spirit, and the reformation carried out by Josiah on the basis of this book is the decisive proof of the influence of the written word as the organ of prophetic ideas. The same influence can be traced in other directions,—in psalms that express the type of individual faith, and in the historical books as they were finally shaped after the fall of Jerusalem, when the old popular narrative was filled out and continued in a spirit of prophetic pragmatism, and with the direct object of enforcing prophetic teaching. The Exile, which robbed Israel of every other inheritance, gave increased value and authority to the written word, and in the author of Isa xl–lxvi we find a prophet who no longer appears in person before his audience but does his whole work by the pen. There are other short prophecies of the Babylonian age, as Isa xiii, xiv, which seem to have been first published as anonymous broadsides—a characteristic change from the method of the former prophets, who wrote only what they had first spoken to the people. The earliest written prophecy is nervous rhetoric of the old pragmatic Hebrew style interspersed with bursts of song. Even before the Exile this style had undergone a change, the prophecies of Jeremiah have lost something of the old force, while they display a subtler habit of reflexion and a pathos which has its origin in the conflict of a sensitive and shrinking temperament with the overpowering sense of prophetic duty. Jeremiah was much occupied with the dark problems of providence and the meaning of the sufferings of the faithful in Israel, a topic which goes beyond the sphere of the earlier prophecy, but forms a chief theme of Isa xl–lxvi, and from a different point of view is taken up and discussed in the book of Job. The last-named book is the highest utterance of another characteristic form of Hebrew literature, the Chokma, that is, wisdom or practical philosophy in parabolic, epigrammatic, and poetic form. The earliest distinct traces of literary cultivation of this philosophy, which from its nature must at first have passed unwritten from mouth to mouth, is the collection of ancient proverbs by scholars in the service of Hezekiah (Prov xxv 1). Along with the simple epigrammatic proverbs which continued to be a favourite vehicle of Jewish thought long after Hebrew had given way to Aramaic, the earliest form of Hebrew wisdom seems to have been the fable about plants and trees (Jud. xi, 2 Kings xiv 9, cf. 1 Kings i 33), so different from the animal fables of Kallig and

Dammag or Sindhu, which the later Semitic literature borrowed from India. The further development of the Chokma ran parallel with the progress of prophecy, and though it is generally maintained that Jeremiah quotes the book of Job, it is perhaps more likely that the contrary is the case, and that the latest and most meditative phase of prophecy was absorbed into the poetry of the Chokma. The brief revival of spoken prophecy after the Exile lacks the old fire, and presents no notable literary fortune except the use of somewhat fantastic symbolic imagery, the prototype of the later apocalyptic literature.

The decadence of prophecy and the synchronous systematization of the ceremonial law on lines first drawn by Ezekiel, mark the commencement of the third and last period of Hebrew literature. The age of religious productivity was past, and the narrow limits and political nullity of the new Jewish settlement under the Persians presented no favourable conditions for a fresh development of truly national literature. The scribes took the place of the prophets and the growth of traditionalism imposed increasing restrictions on original thought. The finest and best products of this period are the post Exile psalms, the hymns of the second temple, which occupy a large part of the Psalter, and, though generally inferior to the older lyrics in the highest poetical qualities, are often full of the charm of genuine feeling and sweet utterance, and sometimes rise to a sublime energy of devotion and faith. With these psalms the graceful prose idyll of Ruth has a natural affinity. The other writings of the last age are on the whole much inferior. As the language decayed, the graces of the older prose style were lost. The memoirs of Ezra and Nehemiah, the colourless narrative of the Chronicles, and even the book of Esther, are singularly destitute of literary merit.

Yet letters were sedulously cultivated. The *Midrash*, or sermonizing treatment of the old history which holds so large a place in later Jewish literature, had come in before the time of the Chronicles, who quote a work of the kind by name—the *Midrash of the Book of Kings* (2 Chron xxv 27, cf. xii 22). Along with this came the beginnings of Haggada, the formation of parables and tales attached to historical names, of which the book of Jonah is generally taken as an early example, and which attains much greater dimensions in the apocryphal additions to the *Trilogia*. And so at the close of the Old Testament period the author of Ecclesiastes could speak of the weariness of much study and the endless sterility of bookmaking. His judgment was confirmed by posterity, for of these many books scarcely a trace remains.

The Cultivation of Hebrew as a Dead Language.²—We have seen that when the latest books of the Old Testament were written Aramaic had already supplanted Hebrew as the language of common life. But the knowledge of the ancient idiom was kept alive not merely by the study of the sacred books but by the continued use of Hebrew for literary purposes. Several books of the Apocrypha appear to be translated from Hebrew originals—Sirach, Judith, 1 Mac—the last according to the express testimony of Jerome. It is even probable that the Old Testament canon contains elements as late as the epoch of national revival under the Maccabees (Daniel, certain Psalms), for Hebrew was the language of religion as well as of scholarship. As for the scholars, they affected not only to write but to speak in Hebrew, but they could not resist the influence of the Aramaic vernacular, and indeed made no attempt to imitate

¹ In the 7th century written instruments were used in sales of property (Jer xxxix 16), and in divorce cases they are recognized in Dent xlv 1.

² On this topic compare in general Wolf's *Bibliotheca Hebraea*, 1716–1733; Bartoloni's *Bibliotheca Aegyptia Rabbinica*, 1875–1893; Imbortoni's *Bibliotheca Latina Hebraica*, 1694; Dintel, *Geschichte des A. T. in der Christlichen Kirche*, 1869; K. Simon, *Kritische Critique des A. T.*, 1878.

by the influence of the synagogue where it is not guided by the Septuagint, and the homilies of Aphraates are a mine of Jewish tradition. In the Middle Ages some knowledge of Hebrew was preserved in the church by converted Jews and even by Christian scholars, of whom the most notable were the Dominican controversialist Raymundus Martin and the Franciscan Nicolaus de Lyta, though whose popular commentaries the exegesis of Rashi was conveyed to Luther and largely influenced his interpretation of Scripture.¹ But there was no continuous tradition of Hebrew study apart from the Jews, and in the 16th century, when the revival of independent scholarship kindled the desire to add a third learned tongue to Latin and Greek, only the most ardent zeal could conquer the obstacles that lay in the way. Orthodox Jews refused to teach those who were not of their faith, and on the other hand the bigotry of ignorant churchmen desired nothing better than the entire suppression of Jewish learning. Even books were to be had with this greatest difficulty, at least north of the Alps. In Italy things were somewhat better. Jews expelled from Spain received favour from the popes. Study was facilitated by the use of the Hebrew printing press, which was at work at Reggio as early as 1476, while the whole Hebrew Bible appeared at Soncino in 1488.² The cause of learning found its champion among the northern humanists in John Reuchlin (1455-1522), whose *Rudimenta Hebraica* (Florence, 1506) opened the door to students, while his victorious contest with Pfefferkorn and the Cologne censors established the claim of Hebrew studies on scholarship and the church.

The new learning spread fast. Sebastian Münster in Heidelberg, and Paul Budlein (Fagus) at Jany, Strasbourg, and Cambridge, were worthy pupils of the famous and liberal Jewish scholar Levita. France drew teachers from Italy. Santes Pagninus of Lucerne was at Lyons, and the trilingual college of Pagninus I. at Paris, of which Vatablus and Le Moerue soon became the ornaments, attracted among other foreigners Guistiniani, bishop of Nubio, the editor of the Genoa Psalter of 1516. In Rome the Jewish convert Felix Pratensis taught by invitation of Leo X., whose name and that of the more famous convert J. b. Hayyim live mainly in connexion with the great Rabbinical Bibles that issued from the Bomberg press at Venice. In Spain, the old home of Jewish scholarship, Hebrew learning was promoted by Cardinal Ximenes, the patron of the Complutensian Polyglot. Printing presses were multiplied, and the great humanist printers as Froben at Basel and Estienne at Paris, competed with Italy in the production of Hebrew books. In brief, before the middle of the 16th century the place of Hebrew studies was secure throughout learned Europe, while in Protestant countries opposition to the authority of the Vulgate combined with scholarly interest to make the study of the original text of Scripture appear indispensable. Thus in Scotland the establishment of a trilingual course in the universities is contemplated in the first *Book of Discipline*.³

For a time the best Christian scholars leaned mainly on

the Rabbins. But in the larger air of humanism a more independent type of learning soon arose, of which Le Moerue in the 16th and Drusius in the beginning of the 17th century may be taken as representatives. The importance of the ancient versions was recognized, and their study was fostered by the publication of the *Polyglots*.

In the 17th century the cognate dialects were cultivated with great vigour and success by men like Selden, Castell, and Pococke in England, De Dieu in Holland, Bochart in France, Ludolf and Hottinger in Germany, and these studies bore fruit both for the Hebrew grammar and for the lexicon. Rabbinic learning was not forgotten, and found its chief exponent in the elder Buxtorf at Basel, who was also the author of grammars and a handy lexicon which long remained favourite manuals in England and on the Continent.⁴

At the same time a critical spirit arose, which involved Hebrew philology in the meshes of theological controversy. The battle as to the age of the vowel points has already been referred to. It was part of a larger question as to the integrity of the received Hebrew text, and the legitimacy of text criticism, which received dogmatic importance from the prevalence of extreme theories of verbal inspiration in the Protestant Church. Thus the Protestant Cappelins found his main support in the Catholic Church (Morinus, R. Simon), while the authority of the Masoretic text and punctuation was elevated to a dogma in the *Formula Consensus Helvetica* (1675), not without protest from the wiser Protestantism of France. The critical school had also its extravagances, and an undue depreciation of tradition was one of several false principles that it would be tedious to enumerate, which came into vogue in the latter part of the 17th century, and long continued to impede the progress of scientific Hebrew philology. In the beginning of the 18th century Samuels studied hard, then chief seat in Holland, where Albert Schulenius took up the comparative method with fresh energy, and applied it to Hebrew on a scale which gave a new shape to the study of the language.⁵ Schulenius laid emphasis on the limited extent of the Old Testament literature, which makes it an inadequate record of the phenomena of the Hebrew language, and proposed to supply these defects by a large use of the dialects, mainly of the Arabic, in which he had wide and accurate reading. His *Institutiones ad fundamenta Linguae Hebraeae* (1737) mark an advance on previous grammars, and in his commentaries is accumulated an enormous mass of material of the highest value for the lexicographer. Schulenius found an influential school, of which Schoeder was the chief ornament, but his method was easily abused, and fell into discredit in the hands of arbitrary expositors like Venema. After Holland, Germany became the chief seat of Hebrew studies. In Halle, where the influence of Francke directed special attention to Biblical learning, there sprang up contemporaneously with the Dutch school a school of Hebraists,—earnest, laborious, and thorough, but somewhat jejune and deficient in æsthetic sympathy,—of which the Michaelis family were the chief representatives. J. D. Michaelis (1717-1791) executed a sort of sovereignty in Hebrew letters, and the stamp of Halle has left a permanent impress on the German schools, though a more sympathetic and emotional type of scholarship, beginning with Heider and Eichhorn, became dominant under the influence of Ewald.

¹ To obtain an idea of the way in which Hebrew was taught in the 17th century one may read the *Dietsche van Caspar Schoppen, in II Grote en kleine dissertatien over de studien vasterlandse* (Amst., 1645).

² On Schulenius, his method and school, see O. Sapp, *Johannes Schultens en zijn tijd* (Amst., 1896). The Dutch schools of the 16th and 17th centuries are well described by the same author, *Het godgeleerd Onderwijs in Nederland gedurende de 16de en 17de eeuw* (Leiden, 1878-79).

¹ See Buxtorf's essay in Merz's *Archiv*, i. 428, n. 88.

² De Boun, *Annales Hebœon Typographicae* See XV, p. 100, 1795. A lively picture of the difficulties that lay in the way of Hebrew study is found in the *Autobiography* (ed. Ruggenbach, 1877) of Conrad Feller, who contributed to Reuchlin's *Augurthe Philosophen* the first imperfect Hebrew grammar composed by a Christian (Strasbourg, 1504), republished in facsimile by Nettle, Tübingen, 1877). See also Gugen's *Johnson Reuchlin* (Leipzig, 1871). References may also be made to the same author's *Studien der Ioh. Spr. in Deutschl.* See *Briefe des 15ten bis zur Mitte des 16ten Jahrhunderts* (Breslau, 1870), and *Jour d'un d'Israël. De l'enseignement de l'Hebreu dans l'université de Paris* (1868).

³ The first Hebrew grammar published in Scotland is that of John Row, moderator of the school of Perth, and afterwards minister at Aberdeen, (Glasgow, 1644). The first Hebrew text dated 1687. With the grammar appeared a *Kalilah Hebraica*.

By the epoch-making labours of Silvestre de Sacy (1758-1838), which first placed Oriental learning and especially Semitic grammar on a broad and thoroughly scientific footing, a new impulse was given to Hebrew philology, which since that time has moved with the advance of general Semitic studies, and can hardly again fall into deviant paths. The great teachers of Hebrew in the present century have been two Germans, Gesenius and Ewald,—the former excelling in method and lucidity of exposition, the latter in range of view and creative fertility of ideas. Among the direct or indirect disciples of these great scholars may be reckoned almost every Hebraist in Europe, and to them is mainly due the revival in England of a branch of learning which had almost become extinct through the prevailing distastefulness of last century.

Helps to the Study of Hebrew.—Gesenius.—The seminal product in this class is, those of Gesenius, his *Idi*, and Ohlshausen's *Gesenius's Idiotikon*, his *Lehrbuch der hebräischen Sprache* (Leipzig, 1817), is still useful for occasional reference. His smaller grammar has proved through numerous editions, and in its most recent shape, as it is by Rodiger and finally by Kautsch (1878), holds its ground as one of the best books for learners. Davison's version of Rodiger's Gesenius is the best of several in English translations (1865-1876). The method of Gesenius is mainly canonical. Much more philosophy, but less simple and sometimes abrupt in its tone in his, in the *Ausführliches Lehrbuch der Hebräi* (5th ed., Göttingen, 1870), of which the "Syntax" has been translated into English by Davison (1870). The *Idiotikon* for *Arav* (1870) 1871, Eng. trans. by Smith, 1870) is valuable, but too difficult for ordinary learners. Ohlshausen's *Hebräi* (Bonn, 1861) is incomplete, the author's living name appeared, but it is, on the whole, the best and most accurate exposition of the Hebrew grammatical forms. Two excellent grammars on Ohlshausen's system have been translated into English.—Buckell's *Grammars* (Leipzig, 1860-1870, English by Curtis, 1877) and Lind's *Hebräische Grammatik* (Münster, 1869, Eng. trans. by Peile, 1878). The latter work has some peculiarities which detract from its utility, and neither Buckell nor Lind supplies a proper syntax. Muller's *Schulgrammatik* (Halle, 1878) is too mainly on Ohlshausen's method, with the addition of an extensive system of exercises. Dr Davidson's *Introduction to Hebrew Grammar* (3d ed., Eng., 1878) may be recommended to learners as a good practical method and every introduction to the larger scientific grammars. Of other more extensive works may be named Büchler's *Ausführliches Lehrbuch*, posthumously edited by Mühlis (Leipzig, 1866-68), a huge book serving as a sort of grammatical concordance to the Old Testament, Lengerke's *Hebräi Grammatik* (Paderb., 1866-69), which is valuable from the thorough Jewish scholarship of the author, the Latin grammar of Rood's, and in English the works of Kutsch (1862-68) and Green (New York, 1861). Among useful monographs on special points of grammar may be named Wehrle's *Welche Sprache ist in der Status Constructus* (Worms, 1871), E. R. Driver, *The Use of the Tenses in Hebrew* (Oxford, 1874), Gesenius, *Die Hebräische Sprache* (Halle, 1876), Davidson, *Outline of Hebrew Accentuation* (1861). For comparative purposes in the absence of a comparative system of the Semitic languages, which is hoped for from Rome, the hints in Wright's *Arabic Grammar* will be found most valuable.

Lexicons.—For a survey to all other lexicons is the *Thesaurus* of Gesenius, compiled by Rodiger (Leipzig, 1839-1858). Gesenius published also a *Handwörterbuch*—of which the 8th ed. by Mühlis and Volk (Leipzig, 1871-78) contains a good deal of new matter not always important.—and a *Lexicon universale in Latin* (3d ed. by Hoffmann, 1817), of which there is an English translation *The Handwörterbuch* of Furst (2d ed., 1868, Eng. trans. by S. Davidson, 1871), 3d ed. by Furst, 1874) proceeds on very faulty etymological principles and must be used with great caution. On Hebrew synonyms Pappenheim's *Pa'al Shem* (1784-1811) is the principal work.

Concordances.—The *Concordantia* of Buxtorf (1682) was reprinted by Bar (1883). Furst's *Concordantia* (1840) contains a good deal of supplementary matter, part of which is of little use. For the probing the (incomplete) concordance of Noldius (1679, ed. Tynpius, 1784) is useful.

In addition to modern books the advanced student will sometimes find it useful to recur to older works, especially to the Jewish grammars and lexicographers, but these need not be detailed here.

For the late Hebrew period of the Mishna and for the new words and technical terms in the scholastic Hebrew of the Middle Ages, the best lexicon is Buxtorf's *Lexicon Chaldaicum Talmudicum et Rabbinicum* (1640). The recent reprint is not so good. A new lexicon has lately been in the course of publication since 1875 (*Neuhebräisches und Chaldaisches Wörterbuch*). The

beginner will find the *Lexicon hebraico-rabbinico-philosophicum* appended to Buxtorf's small *Lexicon Hebraicum* very useful, and may also consult the treatise in Roland's *Antilexicon Rabbinicum* (1702). In reading Rabbinical Hebrew it is well to have Schlegel's *Compendium Poesie Hebraicae Rabbinicae* (1790). The similar work of Buxtorf is less full.

On the whole subject of this article consult Gesenius, *Ursprung der hebräischen Sprache*, and Schaff (Leipzig, 1877), *Hebräi, Histoire générale des langues Semitiques* (Hls. ed., Paris, 1864). (W R 8.)

HEBREW, EPISTOLARY. The New Testament writing usually known under this name, or less correctly as the Epistle of Paul the Apostle to the Hebrews, bears in the oldest MSS no other title than the words Ἰπὸς Ῥωμαίων, "To the Hebrews." This brief heading embraces the whole information as to the origin of the epistle on which Christian tradition is unanimous. Everything else—the authorship, the address, the date—was unknown or disputed in the early church, and continues to form matter of dispute in the present day. But as far back as the latter part of the 2d century the destination of the epistle "to the Hebrews" was acknowledged alike in Alexandria, where it was ascribed to Paul, and in Carthage, where it passed by the name of Barnabas, and no indication exists that it ever circulated under another title.¹ At the same time we must not suppose, as has sometimes been done, that the author prefixed these words to his original manuscript. The title says no more than that the readers addressed were Christians of Jewish extraction, and this would be no sufficient address for an epistolary writing (xii 22) directed to a definite circle of readers, a local church or group of churches to whose history repeated reference is made, and to which the author had personal relations (xii 19, 28). The original address, which according to custom must have stood on the outside of the folded letter, was probably never copied, and the early and universal prevalence of the present title, which tells no more than can be readily gathered from the epistle itself, seems to indicate that when the book first passed from local into general circulation its history had already been forgotten. With this it agrees that the early Roman Church, where the epistle was known about the end of the 1st century, and where indeed the first traces of the use of it occur (Clement, and *Shepherd of Hermas*), had nothing to contribute to the question of authorship and origin except the negative opinion that the book is not by Paul. Caus and the Muscatini fragment reckon but thirteen epistles of Paul, Hippolytus (like his master Irenaeus of Lyons) knew our book and declared that it was not Pauline. These facts can hardly be explained by supposing that at Rome during the 2d century the book had dropped out of notice, and its history had been forgotten. Clement, Irenaeus, Hippolytus form a tolerably continuous chain, and the central Church of Rome was in constant connexion with provincial churches where, as we shall presently see, the epistle had currency and reputation. Under these circumstances an original trustworthy tradition could hardly have been lost, and it must appear highly questionable whether the author and address of the book were known at Rome even in the time of Clement. The earliest positive traditions of authorship to which we can point belong to Africa and Egypt, where, as we have already seen, divergent views were current by the end of the 2d century. The African tradition preserved by Tertullian (*De Pudicitia*, c. 20), but certainly not invented by him, ascribes the epistle to Barnabas. Direct apostolic authority is not therefore claimed for it, but it has the weight due to one who "learned from and taught with the apostles," and we are told that it had more currency among the churches than

¹ See the full refutation of supposed exceptions to the uniformity of this tradition in Zahn's article "Hebräerbrief" (*Herzog-Platt, R. N.*, vol. v p. 687).

"that apocryphal shepherd of the adulterers" (the Shepherd of Hermas). This tradition of the African Church holds a singularly isolated position. Later writers appear to know it only from Tertullian, and it soon became obsolete, to be revived for a moment after the Reformation by the Scottish theologian Cameron, and then again in our own century by the German critics, among whom at present it is the favourite view. Very different is the history of the Egyptian tradition, which can be traced back as far as a teacher of the Alexandrian Clement, presumably Panteus (Euseb, *Hist. Eccl.*, vi 14). This "blessed presbyter," as Clement calls him, sought to explain why Paul did not name himself as usual at the head of the epistle, and found the reason in the modesty of the author, who, in addressing the Hebrews, was going beyond his commission as apostle to the Gentiles. Clement himself takes it for granted that an epistle to the Hebrews must have been written in Hebrew, and supposes that Luke translated it for the Greeks. Thus far there is no sign that the Pauline authorship was ever questioned in Alexandria. Origen rests on the same tradition, which he refers to "the ancient men." But he knows that the tradition is not common to all churches. He feels that the language is un-Pauline, though the admirable thoughts are not second to those of the unquestioned apostolic writings. And thus he is led to the view that the ideas were orally set forth by Paul, but that the language, arrangement, and some features of the exposition are the work of a disciple. According to some this disciple was Clement of Rome, others named Luke, but the truth, says Origen, is known to God alone (Euseb, vi 25, cf. vi 38). It is not surprising that these limitations of the tradition had less influence than the broad fact that Origen accepted the book as of Pauline authority. From the time of Origen the opinion that Paul wrote the epistle became more and more prevalent in the East. In the West this view was still far from established in the 4th century. But it gained ground steadily, even those who, like Jerome and Augustine, knew the variations of tradition were unwilling to press an opposite view, and in the 5th century the Pauline authorship was accepted at Rome, and practically throughout Christendom, not to be again disputed till the revival of letters and the use of a more critical spirit.

That the received view called for revision could not indeed be questioned when men began to look at the facts of the case. The vacillation of tradition and the dissimilarity of the epistle from the style and thoughts of Paul were brought out with great force by Erasmus in his concluding annotation on the book, where he ventures the conjecture based on a passage of his favourite Jerome, that Clement of Rome was the real author. Luther (who suggests Apollon) and Calvin (who thinks of Luke or Clement) followed with the decisive argument that Paul, who lays such stress on the fact that his gospel was not taught to him by man but by direct revelation (Gal 1), could not have written Heb 1 3, 4, where the author classes himself among those who received the message of salvation from the personal disciples of the Lord on the evidence of the miracles with which God confirmed their word. The force of tradition seemed already broken, but the wave of reaction, which so soon overwhelmed the freer tendencies of the first reformers brought back the old view. Protestant orthodoxy again accepted Paul as the author, and dissenting voices were seldom heard till the revival of free Biblical criticism in last century. As criticism strengthened its arguments, theologians began to learn that the denial of tradition involves no danger to faith, and at the present moment, in spite of the ingenious special pleading of Hofmann (*Die Hebräer Schrift N. N.*, vol. v, Nordlingen, 1873), scarcely any sound scholar will be found to accept Paul as the direct author of this epistle, though

such a modified view as was suggested by Origen still claims adherents among the lovers of compromise with tradition.

The arguments against the Alexandrian tradition are in fact conclusive. It is probably unfair to hamper that tradition with Clement's notion that the book is a translation from the Hebrew, a monstrous hypothesis which has received its *reductio ad absurdum* in the recent attempt of J. H. R. Bisschhoff to reconstruct the Hebrew text (*Das Urtextbuch des Apostels Paulus an die Hebräer*, kritisch wiederhergestellt, &c., Leipzig, 1878). But just as little can the Greek be from Paul's pen. The un-Pauline character of the style, alike in the words used and in the structure of the sentences, strikes every scholar as it struck Origen and Erasmus. The type of thought is quite unique. The theological ideas are set in a different mould, and the leading conception of the high priesthood of Christ, which is no mere occasional thought but a central point in the author's conception of Christianity, finds its nearest analogy not in the Pauline epistles but in John xvi 19. The Old Testament is cited after the Alexandrian translation more exactly and exclusively than is the custom of Paul, and that even where the Hebrew original is divergent. Nor is this an accidental circumstance. There is every appearance that the author was a Hellenist whose learning did not embrace a knowledge of the Hebrew text, and who derived his metaphysical and allegorical method from the Alexandrian ism, that the Palestinian schools.¹

The force of these arguments can be brought out only by the accumulation of a multitude of details too tedious for this place, but the evidence from the few personal indications contained in the epistle is easily grasped and not less powerful. The argument from 1 3, 4, which appeared decisive to Luther and Calvin, has already been refuted to again, we read in xvi 19 that the writer is absent from the church which he addresses, but hopes to be speedily restored to them. This expression is not to be understood as implying that the epistle was written in prison, for xii 23 shows that the author is master of his own movements.² The plain sense is that his home is with them, but that he is at present absent, and begs their prayers for a speedy return. But Paul, if he could say that he had a home at all, had it not in a community of Jewish Christians. The external authority of the Alexandrian tradition can have no weight against such difficulties. If that tradition was original and continuous, the long ignorance of the Roman Church and the opposite tradition of Africa are inexplicable. But no tradition was more likely to arise in circles where the epistle was valued and its origin forgotten. In spite of its divergences from the standard of Pauline authorship, the book has manifest Pauline affinities, and can hardly have originated beyond the Pauline circle, to which it is referred, not only by the author's friendship with Timothy (xii 23), but by many unquestionable echoes of the Pauline theology, and even by distinct allusions to passages in Paul's epistles.³

In an uncritical age these features might easily suggest Paul as the author of a book which was read in MSS

¹ For the Alexandrian element in the epistle consult the list of passages in Hilgenfeld's *Zeitschrift* (Lipsig, 1872), p. 384, and A. Jensen's *Studia Hæreticæ* (Lipsig, 1872), p. 10. B. Cuyper's *Sacra Hæreticæ* (Lipsig, 1872), p. 10. B. Cuyper's *Sacra Hæreticæ* (Lipsig, 1872), p. 10. B. Cuyper's *Sacra Hæreticæ* (Lipsig, 1872), p. 10.

² In x 34 the true reading is not "of me in my bonds," but "on them that were in bonds," viz. the prisoners everywhere. The false reading, which was that of Clement of Alexandria, is probably connected with the tradition that Paul is author.

³ An unambiguous proof that our author had read the epistle to the Romans seems to be in x 30. This is the one Old Testament allusion of the epistle which does not follow the Septuagint (Deut. xxiii 35), but it is worth for word from Rom. x 19. Further signs of dependence on Romans and Corinthians (which require slight) have been collected by Hofmann in Schenkel's *Deut. Lektoren*, i. 520, and Hilgenfeld's *Zeitschrift*, ix. 4 seq.

immediately after the recognised epistles of that apostle, and which contained nothing in its title to distinguish it from the preceding books with similar headings, "To the Romans," "To the Corinthians," and the like.¹ A similar history, as Zahn has pointed out, attaches to the so-called second epistle of Clement to the Corinthians.

When we see that the tradition which names Paul as author does not possess an authentic historical basis, we are necessarily carried on to deny historical authority to the subsidiary conjectures or traditions which speak of Luke and Clement of Rome. The history of the Alexandrian tradition shows that these names were brought in merely to lessen the difficulties attaching to the view that Paul wrote the book exactly as we have it. The name of Luke seems to be a conjecture of the Alexandrian Clement, for it has no place in the tradition received from his master. And Origen attaches no importance to either name. Some had mentioned one, and some the other, but God alone knows the truth. We have no reason to think more highly of these suggestions than Origen did. Indeed, no Protestant scholar now proposes the name of Clement, whose extant epistle to the Corinthians shows his familiarity with the epistle to the Hebrews, and at the same time excludes the idea that he composed it. The name of Luke has still partisans—most notably Delitzsch, who has carefully collected linguistic parallels between our epistle and the Lucan writings (*Commentatio sum Hebraeos in vultu*, Leipzig, 1857, English translation, Edinburgh, 1868-70). The arguments of Delitzsch are generally met with the objection that our author must have been a born Jew, which from his standpoint and culture is in the highest degree probable, though not perhaps absolutely certain. In any case we cannot suppose that Luke wrote the epistle on Paul's commission, or that the work is substantially the apostle's, for such a theory takes no account of the strongly marked individuality of the book in thought and method as well as expression. And the theory that Luke was the independent author of the epistle (Grotius and others) has no right to appeal to antiquity, and must stand entirely on the very inadequate grounds of internal probability afforded by language and style.

If Alexandria fails us, can we suppose that Africa preserved the original tradition? This is a difficult question. The intrinsic objections to authorship by Barnabas are not important. The so-called Epistle to Barnabas was not written by our author, but then it is admittedly not by Barnabas. The superior elegance of its style of our epistle as compared with that of Paul is not inconsistent with Acts xiv 12, nor is there, as we shall see presently, any real force in the once favourite objection that the ordinances of the temple are described with less accuracy than might be looked for in Barnabas, a Levite and one who had resided in Jerusalem. On the other hand it is hard to believe that the correct account of the authorship of our book was preserved only in Africa, and in a tradition so isolated that Tertullian seems to be its only independent witness. How could Africa know this thing and Rome be ignorant? Zahn, who is the latest exponent of the Barnabas hypothesis, argues that in the West, where the so-called epistle of Barnabas was long unknown, there was nothing to suggest the rise of Barnabas as an author, that the true tradition might push the more readily in other parts of the church after the name of Barnabas had been falsely attached to another epistle dealing with the typology of the ceremonial law, and finally, that the false epistle of

Barnabas, which was first so named in Alexandria, nay there have carried off its true title of the epistle to the Hebrews after the latter was ascribed to Paul. That is not plausible, and it is more likely that an epistle which calls itself *λόγος παρακλήσεως* (Heb xii 22) was ascribed to the *λόγος παρακλήσεως* (Acts iv 36) in the same way as *Πατριάρχης* was ascribed to Solomon, "the beloved of the Lord" (2 Sam xii 24, 25), from the allusion *עצמי* 2, than that this coincidence of expression affords a confirmation of the Barnabas hypothesis. In short, the whole tradition as to the epistle is too uncertain to offer much support to any theory of authorship, and if the name of Barnabas is accepted it must stand mainly on internal evidence.

Being thus thrown back on what the epistle itself can tell us, we must look at the first readers, with whom, as we have already seen, the author stood in very close relations. It is generally agreed that the church addressed was composed of Hebrews or Christians of Jewish birth. We are not entitled to take this simply on the authority of the title, which is hardly more than a reflection of the impression produced on an early copyist. But it is plain that the writer is at one with his readers in approaching all Christian truth through the Old Testament. He and they alike are accustomed to regard Christianity as a continuous development of Judaism, in which the benefits of Christ's death belong to the ancient people of God and supply the shortcomings of the old dispensation (iv 9, x 1, xii 12). With all the weight that is laid on the superiority of Christianity, the religion of finality, over Mosesism, the dispensation which brought nothing to its goal, the sphere of the two dispensations is throughout treated as identical, without any allusion, such as could hardly have been avoided in addressing a Gentile church, to the way in which strangers and foreigners (Eph ii 19) had been incorporated with the people of God. Schurer indeed (*Stud u. Krit.*, 1876, p. 776) has sought such an allusion in vi 1, 2, where faith in God and belief in the resurrection and the judgment, points common to Judaism and Christianity, are ascribed to the elementary doctrine of Christ, and he concludes that the readers addressed were Gentile converts of a Judaizing type. But taken with the context these verses imply only that the Hebrews required to be warned against losing hold even of these first principles of revealed truth which lie in the Old Testament (v 12). From all this we are not perhaps entitled to conclude that the church addressed contained no Gentile members, but it is plain that they were not sufficiently numerous and independent in their way of thought to affect the general type of Christianity in the community. To some writers the emphatic "all" in xii 24, the admonitions x 26, xii 17, have suggested the possibility that the Hebrews addressed were but part, and a somewhat discontented part, of a larger community in which Gentile elements had a considerable place. But this appears a strained conclusion (Phil iv 21, 1 Th v 26) distinctly contrary to the general tone of the epistle, which moves altogether outside of the antithesis between Jewish and Gentile Christianity. We must think not of a party but of a church, and such a church can be sought only in Palestine or in one of the great centres of the Jewish dispersion. That the epistle was addressed to Palestine, or more specifically to Jerusalem, has been a prevalent opinion from the time of Clement of Alexandria, mainly because it was assumed that the word Hebrews must naturally mean Jews, whose mother-tongue was Aramaic. But the term has this restricted sense only when put in contrast to Hellenists. In itself, according to ordinary usage, it simply denotes Jews by race, and in Christian writings especially Jewish Christians. And there are several things in the epistle that seem to exclude Palestine, and above all Jerusalem. The Hellenistic cul-

¹ The place of the epistle in MSS varies. The order of our Bible is that of the Latin Church, the oldest Greek codices placing it before the pastoral epistles. But the Latin order, which expresses the original vacillancy of the Pauline tradition, was formerly current even in the East.

ture of the writer and the language in which he writes furnish one argument. Then the most marked proof of Christian love and zeal in the church addressed was that they had even been assiduous in ministering to the saints (vi 10). This expression may conceivably have a general sense (1 Cor. xvi 15²), but it is far more likely that it has the specific meaning which it generally bears in the New Testament, viz., the collection of alms for the church in Jerusalem. At any rate it was clearly understood in the first age of Christianity that the Judean Church took alms and did not give them, receiving in temporal things an acknowledgment for the spiritual things they had imparted (Rom. xv 27). In fact the great weight laid in the epistles of Paul on this—the only manifestation of the hospitality of the church then possible (Gal. ii 10)—alone explains the emphasis with which our author cites this one proof of Christian feeling. Again, the expressions in ii 3 already referred to imply that the readers did not include in their number direct disciples of Jesus, but had been brought to Christ by the words and miracles of apostolic missionaries now dead (xii 7). This conversion, as it appears from x 32, was a thing of precise date immediately followed by persecution (note the aorists *persecutiones*—*trépelevare*), so that we cannot think of a second generation in the Palestinian Church, but are referred to some part of the Diaspora. Against these difficulties, which have led some of the latest defenders of the Epistle to an Alexandrian (who, in Hilgenfeld's *Zeitsch.* 1870, proposes Jamnia) and Moulton (*New Testament Commentary for English Readers*, vol. ii., 1879), to give up Jerusalem altogether, while others, as Riehm, suppose that the Hellenists of Jerusalem (Acts vi 1) are primarily addressed, it is commonly urged that the readers are exposed to peculiar danger from the persecutions and solicitations of unbelieving Jews, that they are in danger of relapsing into participation in the Jewish sacrifices, or even that they appear to have never ceased to follow the ceremonial observances that had then centre in the temple ritual. The capital argument for this is drawn from xii 13, where the exhortation to go forth to Jesus without the camp is taken as an injunction to renounce fellowship with the synagogue and with the ceremonies and ritual of Judaism. But this exegesis rests on a false view of the context, which does not include verse 9, and expresses by a figure that Christians (as the priests of the new covenant) have no temporal advantage to expect by their participation in the sacrifice of Christ, but must be content to share his reproach, renouncing thus earthly country for the heavenly kingdom (*cf.* xi 16, 25–27 with xii 14, Phil. iii 20). Altogether, this view of the situation of the first readers of the epistle appears distorted or exaggerated. It is obvious that our Hebrews were familiar with the law, and had a high regard for the ordinances of temple worship. In particular it appears that they had not fully understood how the mediatorial functions of the Old Testament were superseded by the mediatorialship of Christ. But their ritualism seems to have been rather theoretical than practical. Had they been actually entangled in the daily practice of superseded ordinances, the author, whose insight into the true worth of these ordinances is clear, and whose personal relations to the Pauline circle are obvious, could hardly have been so nearly one of themselves as appears in xii 19, and at any rate could not have failed to give an express precept on the subject. But, on the contrary, he is in thorough sympathy with the type of doctrine on which their church was formed (xii 7), the easy way in which he touches on the "meats and drinks and diverse washings" of Judaism seems to show that on this head he could count on carrying his readers along with him, and xii 9 hardly refers to sacrifices or to Levitical laws of clean and unclean, but

rather to some such form of asceticism (*cf.* ver 4) as is spoken of in Rom. xiv. Nowhere does our author speak a warning against participation in sacrifices, nowhere does he touch on the burning questions that divided the Pharisaic Christians of Jerusalem from the converts of Paul. The practical lesson which he draws from his doctrine is that his readers ought to use with diligence the specifically Christian way of access to God (x 19 seq.), and the only positive fault which he mentions in this connexion is a disposition to neglect the privilege of social worship (x 25). This again is plainly connected, not with an inclination to return to the synagogue, but with a relaxation of the zeal and patience of the first days of their Christian profession (vi 4 seq., x 32 seq., xii 1 seq.), associated with a less firm hold than they once had of the essentials of Christian faith, a less clear vision of the heavenly hope of them calling (ii 12, iv 11, v 12). The apostle fears lest they fall away not merely from the highest standpoint of Christianity into Judaizing practices, but from all faith in God and judgment and immortality (ii 12, vi 1 seq.)¹

For the solution of the problem of the epistle it is of the highest importance to form an exact conception of the causes and nature of this unhealthy condition of the church. Their first conversion had been followed by direct persecution, which their faith had triumphantly overcome. But these days were long gone by (x 32). It does not appear that a like severity of trial had again fallen upon them. But there were persecutions at least in other parts of the church (xii 3, 23). The times were troubled, and from day to day there were many trials and many reproaches to sustain. The dull and long continued strain of conflict with surrounding wickedness was harder to bear than a sharp onslaught of the enemy (*cf.* xii 1). They were weary of enduring, weary of hope deferred, and so the bonds of their Christian unity were loosened, their brotherly love weakened (xii 1 seq.), and they began to doubt the verity of those heavenly good things which their first faith had so vividly realized. In such circumstances it was natural that the writer should lay stress on the contrast between the eternal and the transitory, the things of faith and the things of sight, the heavenly Zion and the earthly pilgrimages. But the remarkable feature of the epistle is that this contrast is drawn out in the form of a threefold argument to show the superiority of Christianity over the old dispensation, inasmuch as Christ is superior (1) to the angels, (2) to Moses, (3) and chiefly to the Levitical priesthood and its mediatorialship. In each of these relations, it is argued, the old covenant, which is earthly, temporal, and without finality, contains within itself the evidence of its own imperfection, and points to the time when it shall be superseded by a new covenant in which every reality and every hope is heavenly, eternal, or, as we should say, ideal. It is in the form of this argument which mainly gives force to the common impression that the Hebrews addressed were in danger of seeking access to God by the superseded methods of the old dispensation—an error, that the epistle is a warning against an Ebionite tendency to Christian Pharisaism. But to such a tendency, as we have seen, the practical admonitions of the epistle by no means point. To some scholars accordingly, and particularly to Reuss (*Histoire de la Théologie Chrétienne*, liv. v. chap. 1, *Les Épîtres Catholiques*, Paris, 1878), the theoretical part of the book has seemed disproportionate to the practical and personal conclusion, and it has been proposed to regard the whole as a theological system with an expository appendix. Doubtless this view contains an element of truth. In a

¹ The statement of Renan, *L'Antiquité*, pp. xiv, 215, 216, that some had already fallen away and that the question of their return was being agitated, seems to be part of the ingenious historical romance in which he has enveloped the whole origin of the epistle.

far higher measure than the Pauline epistles, and in a sense which thoroughly well agrees with the position of the author as no apostle but an apostolic convert; the book presents the marks of theological reflection on the established data of the faith. Yet it is impossible to ignore the fact that a special and practical motive runs through the whole book. The author never loses sight of a definite circle of readers, and the vast scope of his argument, which is at once felt in the dignity of the opening verses, so unlike the commencement of an ordinary letter, appears to be directly suggested by some historical circumstance affecting his readers and himself, but nowhere explicitly set forth in the epistle, which brought the trial of their faith into close connexion with the question of the permanence of the temple and its ritual. Now we have seen reason to believe that these Jewish Christians were not Palestinians of an Ebionite type but men of the Hellenistic dispersion, with a possible tendency to ascetic mysticism, and almost certainly of such a habit of thought as enabled them readily to sympathize with the typological method of our author. Among men of this type there was no great danger of a relapse into practical ceremonialism. They would rather be akin to the school of Judaism characterized by Philo (*De Uis. Ab.*, c. xvi., ed. Mangey, i 450), who neglected the observance of the ceremonial laws because they took them as symbols of ideal things. Occupying this position before their conversion, then adoption of the Christian faith would not have forced upon them any close examination of the relation of the new dispensation to the old law. But it appears from Philo that the men who spiritualized away the Sabbath, the great feasts, even circumcision itself, were not prepared to think lightly of the sacred ritual of the temple. The holy hill of God, the meeting-place of heaven and earth, with its stately service and its ancient memories, had too central a place in the religion of the old covenant to seem indifferent to the freest thinker. And so our Hebrews, whose acceptance of Christ had not shaken their sense of the continuity of the people of God and their Old Testament privileges, might readily retain the feeling that the ritual of the temple was still what it was of old—a visible and necessary pledge of God's approach to His people and His acceptance of their worship. So long as things ran their old course such a feeling would hardly affect the even tenor of their Christian life. But when the death struggle of Judea against Rome drew the sympathy of every Hebrew heart, when the abomination of desolation stood in the holy place, when the holy and beautiful house was burned up with fire, and when, with all this, terror and distress filled the whole Roman empire and still the Lord delayed His coming, it was not strange that something like despair of God's help should assail our Hebrews, and that all the hopes of the people of God should seem threatened in the overthrow of the ancient pledge of Jehovah's nearness to Israel.

Now it has generally been argued that the epistle to the Hebrews, which describes the temple services in the present tense, must necessarily have been written before they ceased to be performed. But it has been shown in the most conclusive manner, from the use of similar presents in Rabbinical writers as well as in Josephus and elsewhere, that this argument goes for nothing, and the most recent writers, among Holzmann's discussion of the subject in Schenkel's *Bibel-Lexikon*, ii 823 seq., generally admit that the epistle may have been written after the fall of the temple. And if this be so it can hardly be questioned that the most natural view of the apostle's argument, as it comes to a point in such passages as vii 18, ix 9, is that the disappearance of the obsolete ritual of the old covenant is no blow to Christian faith, because in Christ ascended into glory the church possesses in heavenly ventry all that the

old ritual presented in mere earthly symbol. It was the ruin of the Jewish state and worship which compelled Christianity to find what is offered in our epistle—a theory of the disappearance of the old dispensation in the new.

Many attempts have been made to determine which of the centres of the Diaspora was the seat of our Hebrews. Hofmann suggests Antioch, Ewald, Ravenna,¹ but Rome and Alexandria are the places for and against which most has been said. One argument for Alexandria on which great stress has been laid must certainly be dismissed. Wieseler (*Untersuchung über den Hebräerbrief*, ii 5 Halft., Kiel, 1861), combating the arguments against a Palestinian address with the impression, which we have seen to be without sufficient foundation, that the readers lived in the neighbourhood of a Jewish temple, seeks them among the Egyptian Jews who frequented the schismatical temple of Leontopols (Tel-el-Yahdita) in the upper Delta. And he tries to show that in his description of the temple and the functions of the high priests our author diverges from the Judean pattern and follows peculiarities of the Egyptian temple. But this argument rests on a series of implausible assumptions. The supposed peculiarities of Onias's temple are proved by arbitrary exegesis from passages of Philo, who apparently never thought of that temple at all. Nor can it be shown that it had even such a reputation as to play the part which Wieseler assigns to it. As our author's supposed ignorance of the Jerusalem ritual is not made out, in the true text of x 11 the high priest is not mentioned, and in vi 27 what is asserted of the high priest is, not that he offered daily sacrifice, but that he was in daily need of atonement. It is more difficult to understand why in ix 4 the golden θυμιατόθυρον, that is, the censer or incense-altar,—for the usage of the word does not determine which is meant,—is assigned to the Holy of Holies. But a passage from the almost contemporary *Apocalypses of Isaiah*, to which Harnack has directed attention (*Stud. u. Krit.*, 1876, p. 572 seq.), similarly connects the censer with the Holy of Holies, and seems to show that our author here proceeds on a current opinion and has not simply made a slip.² Apart from Wieseler's arguments, there is still something to be said for Alexandria. The use in ch. xi of 2 Maccabees, an Egyptian Apocryphon,³ the general sympathy of the argument with Alexandrian thought, the apparent analogy between our Hebrews and the free-thinking Jews of whom Philo speaks, are all in favour of this address, though we do not know enough about the early history of the Egyptian Church to speak with positiveness either for or against this view of the epistle. Among Continental scholars the disposition at present is to favour the Roman address, upon which view, since that church was a mixed one, we must suppose that the letter was originally directed to a Jewish section of the Roman Christians. This is not quite plausible, especially since we find in the epistle no trace of the division of parties alluded to by Paul in his epistle from Rome to the Philippians. It is argued, however, that there is an analogy between the way of thinking of our Hebrews and the disposition of the majority of the Roman Church as it appears in Rom. ix seq. The persecution x 32 is supposed to be that of Nero, in which case θανάσιμον may literally mean "exposed as a public spectacle," and xiii 7 is taken as an allusion to the martyrdom of Peter and Paul. In working

² The Synac was in Durak in Punt. To the passages cited by Harnack to establish for this word the sense of censer, not incense-altar, may be added Ben Ah ed. Hofmann, No 2878, Baileh, Chron. Zool., p. 507, Ezek. vii 11 (Peck and 381 Hex.).

³ Professor Plumptre, in the *Expositor*, vol. 1, has also traced analogies with the book of Wisdom.

James V. still kept a sort of semi-state in Skye. There was also the Macdonalds of Glenshiel and Glenquoy (descendants of Somerled), with the powerful houses of Mackinnon of Dunvegan and Macleod of Harris, McNair of Barra and Macleod of Mull. Peace, consequently, prevailed throughout the 16th and 17th centuries among the rival clans and their dependent tribes, and the turbulent spirit was not subdued till a comparatively recent period. James VI. made an abortive endeavour to colonize Lewis. William III. and Queen Anne attempted to mislead the chiefs in order to preserve tranquillity, but the war of Montrose and Dundee, and the Jacobite insurrections of 1715 and 1745, showed how futile were all such efforts. It was not till 1748, when a desperate battle was struck at the close of the Jacobite rebellion, that the able jurisdiction, and the appointment of sheriffs in the difficult districts, that the acts of peace and social improvement made way in these remote regions.

The change, we are great, and at first not unmixt with evil. A new system of management and high rents was imposed, in consequence of which numbers of the tacksmen, or large tenants, emigrated to America. The crofters continued for many years till the farming on a large scale was not introduced, and the crofters were thus left to villages of barren corners of the land. The consequence was that, despite the numbers who entered the army or were sent to America, the stand out of civilization sunk lower, and the population multiplied in the islands. The people came to subsist almost entirely on potatoes and hennings, and in 1846, when the potato blight commenced its ravage, a scene of such universal destitution ensued,—a plague sweeping over the islands generally, 70 per cent. of the population. Temporary relief was administered in the shape of employment on roads, and other works, and an emigration fund being raised, from 4000 to 8000 of the people in the most crowded districts were removed to America.

The principal books on the Hebrides are Munro's *Description of the Western Islands of Scotland*, 1724; Pennant's *Tour to Scotland and Fingert, to the Hebrides*, 1774; Sir Joseph Banks' *Journal to Pennant's Tour*, Boswell's *Tour to the Hebrides with Samuel Johnson*, 1774; Macculloch's *Geological Account of the Hebrides*, 1819; Hugh Miller's *Geology of the Hebrides*, W. A. Smith's *Geographical and Statistical Description of the Hebrides*, 1874. A rich history and ethnography is given in the *Chronique Régionale de l'Islande et de l'Islande*, edited with learned notes, from the MS. in the British Museum by Professor P. A. March of Orléans, 1890.

HEBRON, the most southern of the three cities of refuge west of Jordan (Josh. x. 7), built "seven years before Zaan (Tanis) in Egypt" (Num. xiii. 22). Tanis, according to Bingham, was standing at least 3400 years B.C. Hebron was originally called Mamie and Kinyath Aiba, after Arba, one of the Anakim (Josh. xiv. 15). It is frequently mentioned in the Old Testament (Gen. xxi. 18 and xxiii. 19, 2 Sam. iii. 20 and v. 5). The present town encloses the *Umm el* sanctuary built over the supposed site of Machpelah, but if this site be (as seems probable) genuine, the ancient Hebron must have faced the cave, as is remarked by many ancient writers (Gen. xxiii. 17). The name Machpelah signifies "place of division," and the cave was therefore called as early as the 6th century *Syntheses Duplex*. In the 12th century an iron door (still visible) is mentioned as leading from the Hebron wall to the cavern. In 1187 A.D. Hebron became the see of a Latin bishop, and it was taken in 1187 by Saladin. In 1834 it joined the rebellion against Ibrahim Pasha, who took the town and pillaged it. Modern Hebron rises on the east slope of a shallow valley—a long narrow town of stone houses, the flat roofs having small stone domes. The main quarter is about 700 yards long, and two smaller groups of houses exist north and south of this. The hill behind is terraced, and terraced vineyards surround the place, which is well watered on the north by three principal springs, including the Well Surah, now *Umm Sârah* (2 Sam. iii. 36). Three conspicuous minarets rise, two from the Hebron the other in the north quarter. The population includes 17,000 Moslems and 600 Jews. The Bedawin bring wool and camel's hair to the market, and glass bangles, lamps, and leather water-skins are manufactured in the town. The modern name of Hebron is *El Khâlîl*, "the friend," in allusion to Abraham the friend of God. The most conspicuous building is the *Haram*, an enclosure measuring

112 feet east and west by 198 north and south, surrounded with high rampart walls of masonry similar in size and dressing to that of the Jerusalem Hebron walls. These ramparts are ascribed by architectural authorities to the Herodian period. The interior area is partly occupied by a 12th century Gothic church, and contains six modern cenotaphs of Abraham, Isaac, Jacob, Sarah, Rebecca, and Leah. The cave beneath the platform has probably not been entered for at least 600 years. The numerous traditional sites now shown round Hebron are traceable generally to medieval legendary topography, including the tombs of Adam, Enoch, Judah, Abner, and Jesse, the Field of Damascus, the Vale of Tears, and the Oak of Mamie ("plain" in A.V. Gen. xiii. 18), which has at various times been shown in different positions from $\frac{1}{2}$ mile to 2 miles from the town.

HECATEUS, son of Hegesander, was sprung from an ancient and noble family of Miletus. His life seems to fall between the years 550 and 475 B.C. His earlier years were spent in travelling. He lived some time in Egypt (Hec. i. 113), he was well acquainted with the resources and power of the Persian empire (Hec. i. 34), and the extant fragments of his writings seem to imply personal acquaintance with Libya, Spain, and Italy, as well as with the countries bordering on the *Ægean* and *Ægean* seas. After middle life, he seems to have settled in Miletus, where he occupied a position of great honour, and to have devoted his time to the composition of geographical and historical works. When Aristagoras held a council of the leading Ionians at Miletus, to organize a revolt against the Persian rule, Hecateus tried to dissuade his countrymen from the undertaking. Being overruled, he then advised them to equip a strong fleet, using for the emergency the treasures of the temple at Branchidae, which might be repaid after the war. But both then and at a later period of the war (Hec. i. 124) his skillful and prudent advice was given in vain. When the remainder of the revolted Ionians fled for terms, he was one of the ambassadors sent to the Persian satrap Artaphernes. He wrote a work on geography entitled *Περὶ Χώρας* or *Περὶ Περιήγησης τῆς γῆς*, in which he went over the countries of the known world, told their inhabitants, enumerated the towns, and described their situation and history. He improved the map of the world which Anaximander had made. He also wrote a work called *Περὶ Αἰθέραις* or *Τοπικῶν*, describing systematically the traditions and mythology of the Greeks. According to Aelian, he was the first to employ critical method to distinguish myth from historical fact, though he accepts Homer and the other poets as trustworthy authority. Heodotus, though obviously regarding him with respect, often controverts his statements.

HECATEUS of Abdera, sometimes confounded with Hecateus of Miletus, was a Greek historian and philosopher of the 4th century B.C. He was a disciple of Pyrrho and a contemporary of Alexander the Great and Ptolemy Soter. He accompanied the latter in an expedition to Syria, and during the reign of the same prince sailed up the Nile as far as Thebes. Some fragments of works by him on Egypt and on the Hyperboreans still exist. According to Suidas, he also wrote a treatise on the poetry of Hesiod and Homer. Regarding his authorship of a work on the Jews, of which some fragments remain, there is some disagreement among critics, but in all probability he is not the author of it.

The *Hebræus Abderitæ Fragmenta* were collected by P. Zorn, and published at Altona in 1780. See C. Müller, *Histor. Græc. Fragm.*, and Voynis, *De Hebræis in Græc.*

HECATE, a Greek goddess who is never mentioned in Homer, but is of great importance in other parts of the literature as well as in religious observance. The name Hecate, the masculine corresponding form, is a frequent

synthes of Apollo, and though the word *ἑκάτη* is never used exactly as an epithet of Artemis, yet this suggests a close relationship between the two goddesses, which an examination of their functions fully confirms. Their character and attributes stamp both as moon-goddesses. In fact, though often distinguished from Artemis, yet at other times Hecate is identified with her. The worship of Hecate seems to have flourished especially among the wilder tribes of Greek nationality, in Samothrace, Thessaly, and elsewhere, she has, however, been received into the Pantheon of the more civilized Greek races, probably on account of her close resemblance to Artemis, and this is doubtless the meaning of Hesiod's statement (*Theog.* 423) that she alone of all the Titanic powers was left unlistributed in her honours by Zeus. The parentage of Hecate is variously given. Hesiod names her father Perses (a word connected with *Περσεύς*, *Persephone*, &c., all of which denote powers of light) and her mother Astria, the starry sky of night. Zeus and Demeter, Zeus and Hecate, &c., are also named as her parents. Her chief prerogatives or functions are the following:

(1) She is the chief goddess who presides over magic arts and spells, for all incantations naturally were performed by the light of the moon. Medea is in this respect closely associated with her worship. See her prayer in Sophocles, *Rhesus* 71. In Theocritus, *Id.* vii, where a woman's incantation to bring back her faithless lover is given, Hecate is constantly invoked. (2) She is a Chthonian power, and is worshipped at the Samothracian mysteries. She is then closely connected with Demeter. Alone of the gods besides Helios, she witnessed the abduction of Persephone, and, torch in hand (a natural symbol for the moon's light), she assisted Demeter in the search for her daughter (*Igm. Dem.*, 45 *ff.*). She is obviously a by-form of *Περσεφώνη*, who is queen of the lower world as also the moon, the bride of the sun, when at setting he has gone to the lower world. She rules as a terrible power, *Katania*, among the shades (*Οἰρ.*, 48, &c.). (3) As *ἀνδροφύς*, *ανδροφύς*, *ἀνδροφύς*, she lights wanderers on their way by night, and is therefore, along with Hecates, worshipped as patron of roads under the name *ὁδοῖα*. At cross roads she was the director, hence her name *τριστρίτις*, and probably also *τρίμορφος*, *τρίμορφος*, &c. Pillars called *Hecateas*, like the *Hermes*, stood, especially in Athens, at cross-roads and cross-ways. (4) She is the goddess of fertility, and, like Artemis, men, especially over the birth and the youth of wild animals. As the moon measures the months, the moon-goddess in all forms, as Artemis, Helena, &c., presides over birth. (5) It follows easily from the last that she should be the goddess who gives wealth and power. Thus she is celebrated by Hesiod (*l.c.*) On the Acropolis at Athens Hecate Epipygidia, as protectress of the citadel, had a shrine beside the temple of Victory. To Hecate dogs were offered, also honey and black six-lambs, as black victims were offered to other Chthonian deities. She was represented generally as a triple form, holding in the six hands torches, with sometimes a snake, a key, a whip, or a dagger, often with dogs standing beside her. The three heads support a basket, "*καλathos*," such as often adorns the statues of Artemis and Hera. The Hecateas also generally represent her with three heads, occasionally, however, a single-formed Hecate is found, still with torch or key in hand, and sometimes with crescent moon on head.

HECKMOND WYKE, a town of England, in the West Riding of Yorkshire, on the Huddersfield and Bradford Railway, 2 miles N W of Dewsbury and 10 miles S W of Leeds. It occupies a gradually sloping site, and is somewhat irregularly built, although lately it has assumed a more town-like appearance. It possesses a church

dedicated to St James erected in 1831, a market-house erected in 1868, a working men's club established in 1868, a mechanics' institute founded in 1873, a chamber of commerce dating from the same year, and a literary institute established in 1878. There are three board schools, a national school, and a Roman Catholic school, the whole affording accommodation for 1600 scholars. Much has been done for the improvement of the town by draining, and under the provisions of the Dewsbury and Heckmondwyke Waterworks Act of 1876 an ample supply of water has been obtained for domestic and manufacturing purposes. A cemetery with chapels for rich men and dissenters was formed in 1860. The chief manufactures are blankets, and there are also carpet factories, machine shops, dye works, and iron foundries. Coal is extensively wrought in the vicinity. The town is under the government of a local board of health established in 1853. The area of the township is about 700 acres. The population of the town, which in 1801 was only 1742, had in 1871 reached 8300, and is now estimated at 10,000.

HECLA. See ICELAND.
HECTOR, son of Priam and Hecuba, the champion of the Trojans and the monarchy of their city. Læus Paris and other Trojans, he had an Oriental name, Darius, as well as a Greek one, an interesting fact on which many fanciful theories have been founded. He was married to Andromache, daughter of Eetion, king in the Cilician Taurus. By Homer his character is drawn in most favourable colours as a good son, a loving husband and father, and a trusty friend,—religulous without superstition, tenderhearted yet courageous. The one blemish apparent in some parts of the *Iliad* (see Geddes's *Homeric Problem*) is a tendency to presumptions and boastful confidence. He is an especial favourite of Apollo, and later poets even describe him as son of that god. When Achilles, enraged with Agamemnon, deserted the Greeks, Hector drove them back to their ships, which he almost succeeded in burning. Patroclus, the friend of Achilles, who came to the help of the Greeks, was slain by Hector with the help of Apollo. Then Achilles, to revenge his friend's death, returned to the war, slew Hector, dragged his body behind his chariot to the camp, and afterwards dragged it round the tomb of Patroclus. Priam, guarded by Hecates, went to Achilles and prevailed on him to give back the dead body, which was buried with great honour (*l.c.* xiv). Hector was worshipped in the Troad by the Boeotian tribes Gephyriæ, and he is, like other heroes, probably an ancient god. It would require an inquiry into the whole Trojan legend to determine the conception involved. It is impossible to do more in this place than refer to Ruckert's essay in this direction.

Scenes from the life of Hector are favourite subjects in vase paintings. A very ancient vase from Cambray represents his fight with Menelaus over the dead Euphorbus, and on an amphora, also from Cambray, of not later date than 450 B.C., he is represented starting for battle, striding beside the quadriga into which his charioter Cheiron has already mounted. Both vases are now in the British Museum. Though many of the subjects in which he was supposed to appear have now been assigned to other heroes,—for example, the frequently occurring fighting of Hector and Andromache is by a more searching criticism generally transformed into a scene from the life of Amphitrone,—yet many undoubted examples remain. We find such scenes as the parting cup given by Hecate to her son as he departs to the field, his battle with Achilles in presence of Apollo and Athena, or the dragging of his corpse round the tomb of Patroclus.

HECUBA (the Latin form of the Greek *Hekabe*), wife of Priam, is in Homer daughter of the Phrygian king Dymas, who dwelt on the bank of the Sangarius; but according to Euripides, Virgil, &c., she was a mere Cilician. According to Homer she was mother of nineteen of Priam's fifty sons. When Troy was captured and Priam

slain, she was made prisoner by the Greeks. Her fate is told in various ways, most of which connect her with the promontory Cynossema, on the Thracian shore of the Hellespont. According to Euripides (*Hekabe*), her youngest son Polydorus was placed during the siege under the care of Polymestor, king of Thrace. When the Greeks came to the Thracian Chersonese on their way home Hecuba discovered that her son Polydorus had been murdered, and in revenge she contrived to put out the eyes of Polymestor and murder his two sons. She was acquitted by Agamemnon; but, as Polymestor foretold, she was turned into a dog, and her grave became a mark for ships. Other tales about her may be found in Ovid (*Mets.*, xiii. 423 ff.) and Dictys. It is obvious from the tales of Hecuba's transformation and death that she is a form of some goddess to whom dogs were sacred; and the analogy with Scylla is striking.

HEDA, **WILLEM CLAESZ**, Dutch painter, born at Haarlem it is said in 1594, and still living there in 1668, was one of the earliest Dutchmen who devoted himself exclusively to the painting of still life. He was the contemporary and comrade of Dirk Hals, with whom he had in common pictorial touch and technical execution. But Heda was more careful and finished than Hals, and showed considerable skill and not a little taste in arranging and colouring chased cups and beakers and tankards of precious and inferior metals. Nothing is so appetizing as his "luncheon," with rare comestibles set out upon silver plate, oysters, seldom without the cut lemon, — bread, champagne, olives, and pastry. Even the commonplace "refection" is also not without charm, as it comprises a cut ham, bread, walnuts, and beer. One of Heda's early masterpieces, dated 1623, in the Munich Pinakothek is as homely as a later one of 1651 in the Lichtenstein Gallery at Vienna. A more luxurious repast is a Luncheon in the Augsburg Gallery, dated 1644. Most of Heda's pictures are on the Continent, notably in the galleries of Paris, Turin, Ghent, Darmstadt, Götting, Munich, and Vienna. He was a man of repute in his native city, and filled all the offices of dignity and trust in the guild of Haarlem. He seems to have had considerable influence in forming the younger Frans Hals.

HEDGEHOG (*Eriacus europæus*, Linn.), the Common Urohin of Pennant, *Hieroson* of the French, *Riccio* of the Italians, *Igel* of the Germans, is the best known, and from an anatomical point of view perhaps the most characteristic, of the *Insectivora*. The genus is remarkable for its dentition, its armature of spines, and its short tail, while the ordinary species is characterized by not having the spines longer than the head or the ears more than half that length. The upper jaw is longer than the lower one, and the whole snout, which is long and flexible, has somewhat the appearance of that of the hog; the nostrils are narrow; and the claws are long but weak. The animal is about 10 inches long, its eyes are small, and the integument of the ventral surface is covered with hairs of the ordinary character. The brain is remarkable for its low degree of development, the cerebral hemispheres being excessively small, and marked with but one groove, and that a shallow one, on each side, while the more special characters of this region call to mind the organization of the same parts in the very lowest of mammals.

The most remarkable point in its external appearance is the possession of spines, and the power possessed by it of rolling itself up into a ball, from which these spines stand out in every direction. The spines, which are modified hairs, are sharp, hard, and elastic, and form so efficient a defence that there are but few animals that are able, and even they rarely, to effect a successful attack on this curious creature. The moment it is touched, or even hears the sound of so slight a menace as the report of a gun, it rolls

itself up by the action of the powerful muscles which lie just beneath the skin, while this same contraction effects the erection of the spines. The most important muscle is the *orbicularis pinniculi*, which extends over the anterior region of the skull, as far down as the body as the ventral or purely hairy region, and on to the tail; three other muscles are connected with this, and aid in the contraction of the integument, passing as they do from the breast-bone to the face and lower jaw, from the fore-arm to the sides of the ventral region, and from the fore-arm to the dorsal surface.

Though insectivorous, the hedgehog is reported to have a great liking for mice, while frogs and toads, as well as plants and fruits, all seem to be acceptable; its ingestion of snakes has been detailed by Buckland and Broderip, and its fondness for eggs has caused it to meet with the enmity of game-preservers. Pennant reports that "it lies under the undeserved reproach of sucking cattle, and hurting their udders, but the smallness of its mouth renders that impossible," nor does it seem that any well-authenticated report of such an occurrence has ever been made. It makes a not rare domestic pet. In a state of nature it does not emerge from its retreat during full daylight, unless urged out by hunger or by the necessities of its young. During the cold of winter it passes into a state of complete hibernation, and its temperature falls very considerably; having

Hedgehog.

provided itself with a nest of dry leaves, it is well protected from the influences of the rain, and rolling itself up it remains undisturbed till distinctly warmer weather returns. In July or August the female brings forth four to eight young, or, according to others (Ball), two to four at a somewhat earlier period; at birth the spines, which in the adult are black in the middle, are white and soft, but soon harden, though they do not attain their full size until the succeeding spring. It is commonly found in woods and gardens, and extends over nearly the whole of Europe; it has been found at 6000 to 8000 feet above the level of the sea. The which in *Macbeth* who heard the "hedge-pig" *whine* thirco and once gave not an incorrect account of the character of its voice, rarely as this is heard. The adult is provided with thirty-six, and the young with twenty-four teeth; in both cases canines appear to be absent; the median incisors are very long, and project; there are two more false grinders in the upper than in the lower jaw, while the true molars of the upper jaw are remarkable for the presence of four cusps, of which the anterior inner and the posterior outer are connected by an obliquely-set ridge. This is the same arrangement as is seen in man. In the lower jaw the corresponding teeth are, as in the lemur (or *half-ape*), provided with two transverse ridges.

Sixteen species of the genus have been recognized by some zoologists. The tenrec (*Ctenota*) of Madagascar has very many points in common with it.

HEDGE-SPARROW See SPARROW

HEEM, JAN DAVIDSZ VAN (or JOHANNES DE), was born according to Houbraken and Sandart in 1601, according to Descamps in 1600, at Utrecht, and died at Antwerp in 1683 or 1684. *Thou* has said of Heda, but it is only true of De Heem, that "he gloried in insects, butterflies, and all the minute beings that swarm in vegetation, and made the moth drink in cups of chased gold." He was, if not the first, certainly the greatest painter of still life in Holland, no artist of his class combined more successfully perfect reality of form and colour with brilliancy and harmony of tints.

No object of stone or silver, no flower humble or gorgeous, no fruit of Europe or the tropics, no twig or leaf, with which he was not familiar. More frequently he worked with a purpose to point a moral or illustrate a motto. Here the snake lies coiled under the grass, there a sickle rests on blooming plants. Gold and silver tankards or cups suggest the vanity of earthly possessions, salvation is allegorized in a chalice amidst blossoms, death as a quail inside a wreath. Sometimes De Heem painted alone, sometimes in company with men of his school, Madonnas or portraits surrounded by festoons of fruit or flowers. At one time he signed with initials, at others with Johannes, at others again with the name of his father joined to his own. At the intervals he condescended to a date, and when he did this work was seldom of his best. De Heem entered the guild of Antwerp in 1638-9, and became a burgher of that city in 1637. He steadily maintained his residence till 1667, when he moved to Utrecht, where traces of his presence are preserved in records of 1668, 1669, and 1670. It is not known when he finally returned to Antwerp, but his death is recorded in the guild books of that place. A very early picture, dated 1628, in the gallery of Gotha, bearing the signature of Johannes in full, shows that De Heem at that time was familiar with the technical habits of execution peculiar to the youth of Albert Cuyp. In later years he completely shook off dependence, and appears in all the vigour of his own originality.

Out of 100 pictures or more to be met with in European galleries scarcely eighteen are dated. The earliest one, that of Gotha is a chased tankard, with a bottle, a silver cup, and a lemon on a marble table, dated 1610, in the museum of Amsterdam. A similar work of 1645, with the addition of fruit and flowers and a distant landscape, is in the gallery of Berlin. A *chryse* in a vase, with the radiant host amidst wheat-earves, grapes, and flowers, is a masterpiece of 1648 in the Belvedere of Vienna. A wreath round a Madonna of life size, dated 1660, in the museum of Berlin, is the work of De Heem, painted with vigour and harmoniously on a large scale. In the Pinakothek at Munich is the celebrated composition of 1668, in which creeps, beautifully commingled with gourds and blackberries, twigs of orange, myrtle, and peach, is enlivened by butterflies, moths, and bees. A landscape with a blooming rose tree, a jug of strawberries, a selection of fruit, and a marble bust of Pan, dated 1666, is in the Hermitage at St. Petersburg, an allegory of abundance in a mansion washed with fruit and flowers, in the gallery of Brussels, is inscribed with De Heem's monogram, the date of 1668, and the name of an obscure artist called Lambrechts. All these pieces exhibit the master in full possession of his artistic facilities.

CONRADIUS DE HEEM, the son of Johannes, was in practice as a flower painter at Utrecht in 1668, and was still active in his profession in 1671 at the Hague. His pictures are not equal to those of his sire, but they are all well executed, and most of them in the galleries of the Hague, Dresden, Cassel, Vienna, and Berlin. In the Stedael at Frankfurt is a fruit piece, with pot herbs and a peacock's egg, dated 1668; another, dated 1671, is in the museum of Brussels. DAVID DE HEEM, another member of the family, entered the guild of Utrecht in 1668 and that of Antwerp in 1698. The best piece assigned to him is a table with a lobster, trout, and glasses, in the gallery of Amsterdam; others bear his signature in the museums of Florence, London, and Brussels. It is well to guard against the fallacy that David de Heem above mentioned is the father of Jan de Heem. We should also be careful not to make two persons of this name, who sometimes signs Johannes, sometimes Jan Davidsz or J. D. Heem.

HEEMSKERK, JOHAN VAN (1597-1656), Dutch poet, was born at Amsterdam in 1597. He was educated as a child at Bayonne, and entered the university of Leyden in 1617. In 1621 he went abroad on the grand tour, leaving behind him his first volume of poems, *Minnelust* (The Art of Love), which appeared in 1622. He was absent from Holland four years. He was made master of arts at Douves in 1623, and in 1624 visited Hugo Grotius in Paris. On his return in 1625 he published *Amorijdt* (The Duty of Love), and began to practise as an advocate in the Hague. In 1628 he was sent to England in his legal capacity by the Dutch East India Company, to settle the dispute respecting Amboyna. In the same year he published the poem entitled *Minnelust*, or the Science of Love. He proceeded to Amsterdam in 1640, where he married Alida, sister of the eminent statesman Van Buren. In 1643 he published *The Cud*, a tragic comedy, and in 1647 his most famous work, the pastoral romance of *Danversche Avond*, which he had written ten years before. During the last twenty years of his life Heemskerk sat in the upper chamber of the states-general. His last poetical work was *The Inconstant Lilla*. He died at Amsterdam on the 27th of February 1656.

The poetry of Heemskerk, which fell into oblivion during the 18th century, is now once more read and valued. He ranks a prominent place among writers of the second rank in the list of Dutch literature. But his poems, pastoral, the *Batavia Avond*, which was founded on the *Astro de Honore d'Uff*, enjoyed a great popularity for more than a century, and passed through twelve editions. It provided a host of imitations, the number of which the most distinguished was the *Danversche Avond* (1667) of Lambertus Doo, the *Zaanlandsche Avond* (1688) of H. van der Zeeboom, and the *Stedensche Avond* (1708) of Willem van Elger. But the original work of Heemskerk, in which a party of nymphs and shepherds go out from the Hague to Ktuyk, and there indulge in poetic and pastoral discourse, surpasses all these in brightness and variety.

HEEMSKERK, MARTIN JACOBUS (1498-1574), some times called Van Veen, was born at Heemskerk in Holland in 1498, and apprenticed by his father, a small farmer, to Cornelius Willems, a painter at Haarlem. Recalled after a time to the paternal homestead and put to the plough at the milking of cows, young Heemskerk took the first opportunity that offered to run away, and demonstrated his wish to leave home for ever by walking in a single day the 50 miles which separate his native hamlet from the town of Delft. There he studied under a local master whom he soon deserted for John Schoreel of Haarlem. At Haarlem he formed what is known as his first manner, which is but a quaint and *gauche* imitation of the fluid style brought from Italy by Mabuse and others. He then started on a wandering tour, during which he visited the whole of northern and central Italy, stopping at Rome, where he had letters for a cardinal. It is evidence of the facility with which he acquired the rapid execution of a some-painter that he was selected to co-operate with Antonio da San Gallo, Battista Franco, and Francesco Salviati to decorate the triumphal arches erected at Rome in April 1536 in honour of Charles V. Vasari, who saw the battle-pieces which Heemskerk then produced, says they were well composed and boldly executed. On his return to the Netherlands he settled at Haarlem, where he soon (1540) became president of his guild, married twice, and secured a large and lucrative practice. In 1573 he left Haarlem for Amsterdam, to avoid the siege which the Spaniards laid to the place, and there he made a will which has been preserved, and shows that he had lived long enough and prosperously enough to make a fortune. At his death, which took place on the 1st of October 1574, he left money and land in trust to the orphanage of Haarlem, with interest to be paid yearly to any couple which should be willing to perform the marriage ceremony on the slab of

Tschugg Tschugg was the summer residence of the family, near Etchach on the lake of Biel, in winter they lived in Bern. Little happened in these years. Hegel had a few acquaintances in Bern, but, on the whole, intellectually he lived in isolation. He was, however, far from inactive. Local influences may explain a systematic account of the fiscal system of the canton Bern which he made for himself. But the main factor in Hegel's mental growth came from his study of Christianity. Under the impulse given by Lessing and Kant he turned to the original records of Christianity, and attempted to construe for himself the real significance of Christ. He wrote a life of Jesus, in which Jesus was simply the son of Joseph and Mary. He did not stop to criticize as a philologist, and simply ignored the miraculous. He asked for the secret contained in the conduct and sayings of this man which made him the hope of the human race. To Hegel Jesus appeared as revealing the unity with God in which the Greeks in their best days unwittingly rejoiced, and as lifting the eyes of the Jews from a lawgiver who metes out punishment on the transgressor, to the destiny which in the Greek conception falls on the just no less than on the unjust.

The interest of these lucubrations is in general twofold. In Jesus Hegel finds the expression for something higher than mere morality. He finds a noble spirit which rises above the constraints of the sense of duty to the concrete life, seeing the infinite always embracing our finitude, and proclaiming the divine which is in man and cannot be overcome by error and evil, unless the man close his eyes and ears to the godlike presence within him. In religious life, in short, he finds the principle which reconciles the oppositions of the temporal and ordinary mind. But, secondly, this general source of the doctrine that life is higher than all its incidents and codes is of interest. He does not free himself from the current theology either by rational moralizing like Kant, or by bold speculative synthesis like Fichte and Schelling. He finds his panacea in the concrete life of humanity. He turns to history, and not to abstract speculation. But although he goes to the Scriptures, and tastes the mystical spirit of the medieval saints, the Christ of his conception has traits that seem borrowed from Socrates and from the heroes of Attic tragedy, who suffer much and yet smile gently on a destiny to which they were reconciled. Instead of the Hebrew doctrine of a Jesus punished for our sins, we have the Hellenic idea of a man who is calmly tranquil in the consciousness of his unity with God.

During these years of arduous wrestling with the problems of religion, Hegel kept up a slack correspondence with Schelling and Holderlin. Schelling was already on the way to fame. He was trying (to quote his own words) to find the premises to the results of Kant. Meanwhile he kept Hegel abreast with German speculation. Both of them were intent on forcing the theologians from their holes into the daylight, and grudged them any aid they might expect from Kant's postulation of God and immortality to crown the edifice of ethics. After lamenting his want of books, Hegel concludes a letter of 1795 with the words, "Let reason and freedom remain our watchword, and our point of union the church invisible." Great is their animus against the pietistic hypocrisy of Wurtemberg. Meanwhile Holderlin in Jena had been following Fichte's career with an enthusiasm with which he infected Hegel.

After these vehement struggles of thought, it is pleasing to turn to a short tour which Hegel in company with three other tutors made through the Bernese Oberland in July and August 1796. Of this tour he has left a minute diary. It embraced Lauterbrunnen, Grindelwald, the Grimsel, and the valley of the Reuss to the lake of Lucerne. The popular passion for natural scenery had scarcely begun, and the days of hotels and tourists were distant. Our four

tutors carried little luggage, save a pack of cards to while away the hours of rest. Hegel was particularly delighted with the varied play of the waterfalls. Still no glamour blinds him to the squalor of Swiss peasant life. The glaciers and the rocks call faith no raptures. "The spectacle of these eternally dead masses gave me nothing but the monotonous and at last tedious idea, 'Es ist so!'" Again, speaking of the upper parts of the Hasli-thal "I doubt if the most orthodox theologian would be bold enough in these regions to credit nature with the purpose of being useful to man, who with difficulty must wrest from her the scanty pittance of which he can make use,—who is uncertain whether rocks or avalanches may not crush him to pieces even as he steals a poor handful of grass, and destroy his miserable hut and cow-stall, the wretched work of his hands."

Towards the close of his engagement at Bern, Hegel had received hopes from Schelling of a post at Jena. Tired of isolation, he was anxious to get away from Bern. Fortunately his friend Holderlin, who was now tutor in Frankfurt, secured a similar situation there for Hegel in the family of a Herr Gogol, a merchant. Hegel entered upon his new post in January 1797. It was apparently more agreeable, and left more time for study. At the same time he was nearer the centre of public interest. But above all it renewed the much-mused intellectual society. Holderlin was still, as formerly, enamoured of the ideal of ancient Greece. And another friend called Sinclair, a Fichtean, the author of several forgotten philosophical works, helped to animate Hegel's interest in philosophy.

It may have been the political position of Frankfurt that made Hegel about this time turn to questions of economics and government. He had studied Gibbon, Hume, and Montesquieu in Switzerland. We now find him making copious extracts from the English newspapers on the Poor Law Bill of 1796, criticizing the Prussian land laws, promulgated about the same time, and writing a commentary on Sir James Steuart's *Inquiry into the Principles of Political Economy*, as a means of defining his own views on economics. Here, as in contemporaneous criticisms of Kant's ethical writings, Hegel aims at correcting the abstract discussion of a topic by treating it in its systematic interconnections. Church and state, law and morality, commerce and art, are reduced to factors in the totality of human life, from which the specialists had isolated them.

But the best evidence of Hegel's attention to contemporary politics is two unpublished essays—one of them written in 1798, "On the Internal Condition of Wurtemberg in Recent Times, particularly on the Defects in the Magistracy," the other a criticism on the constitution of Germany, written, it is probable, not long after the peace of Lunéville (1801). Both essays show more vigour in pointing out the inadequacies of the present than in suggesting a remedy. Criticism, not construction, is their forte. In the first Hegel showed how the supineness of the committee of estates in Wurtemberg had favoured the usurpations of the superior officials in whom the court had found compliant servants. And though he perceived the advantages of change in the constitution of the estates, he still doubted if an improved system could work in the actual conditions of his native province. The main feature in the pamphlet is the recognition that a spirit of reform is abroad. If Wurtemberg suffered from a bureaucracy tempered by despotism, the Fatherland in general suffered no less. "Germany," so begins the second of these unpublished papers, "is no longer a state." Referring the collapse of the empire to the retention of feudal forms and to the action of religious animosities, Hegel looked forward to reorganization by a central power (Austria) wielding the imperial army, and by a representative body elected by the geographical dis-

tracts of the empire. But such an issue, he saw well, could only be the outcome of violence—"blood and iron." The philosopher did not pass as a practical statesman. He only described the German empire in its nullity as a concept in without existence in fact. In such a state of things it was the business of the philosopher to set forth the outlines of the coming epoch, as they were already moulding themselves into shape, amidst what the ordinary eye saw only as the disintegration of the old forms of social life.

His old interest in the religious question reappears, but in a more philosophical form. Starting with the contrast between a ritual and a positive religion, he regards a positive religion as one imposed upon the mind from without, not a natural growth crowning the fount of human life. A ritual religion, on the other hand, was not, he thought, the one universal religion of every clime and age, but rather the spontaneous development of the national conscience varying in varying circumstances. A people's religion completes and consecrates their whole activity in it; the people lives above its finite life in limited spheres to an infinite life where it feels itself all at one. Even philosophy with Hegel at this epoch was subordinate to religion, for philosophy must never abandon the finite in the search for the infinite. Soon, however, Hegel adopted a view according to which philosophy is a higher mode of apprehending the infinite than even religion.

At Frankfurt, meanwhile, the philosophic ideas of Hegel first assumed the proper philosophic form. "In my scientific training," he says (in a letter to Schelling of November 2, 1800), "which started from more subordinate wants of man, I could not but be forced onwards to science, and at the same time the ideal of youth had to transform itself into the reflective form of a system." In a MS of 102 quarto sheets, of which the three first and the seventh are wanting, there is preserved the original sketch of the Hegelian system, so far at least as the logic and metaphysics and part of the philosophy of nature are concerned. The third part of the system—the ethical theory—seems to have been composed afterwards; it is contained in its first draught in another MS of thirty sheets. Even these had been preceded by earlier Pythagorean constructions envisaging the divine life in divine triangles.

Circumstances soon put Hegel in the way to complete these outlines. His father died in January 1799, and the slender sum which Hegel received as his inheritance, 3154 gulden (about £360), enabled him to think once more of a studious life. At the close of 1800 we find him asking Schelling for letters of introduction to Bamberg, where with cheap living and good beer he hoped to prepare himself for the intellectual exertions of Jena. The epoch was that Hegel arrived at Jena in January 1801. An end had already come to the brilliant epoch at Jena, when the romantic poets, Tieck, Novalis, and the Schlegels made it the headquarters of their fantastic mysticism, and Fichte turned the results of Kant into the banner of revolutionary ideas. Schelling was the main philosophical lion of the time, and in some quarters Hegel was spoken of as a new champion summoned from Swabia by Schelling to help him in his struggle with the more prosaic continuators of Kant. Hegel's first performance seemed to justify the rumour. It was an essay on the difference between the philosophic systems of Fichte and Schelling, tending in the main to support the latter. Still more striking was the agreement shown in the *Critical Journal of Philosophy*, which Schelling and Hegel wrote conjointly during the years 1802-3. So late was the difference between them at this epoch that it, in one or two cases, is not with certainty possible to determine by whom the essay was written. Even at a later period foreign critics like Cousin saw much that was alike in the two doctrines, and did not

hesitate to regard Hegel as a disciple of Schelling. The dissertation by which Hegel qualified for the position of privat-docent—an essay, *De orbitis planetarum*—was probably chosen under the influence of Schelling's philosophy of nature. It was an unfortunate subject. For while Hegel, depending on a numerical proportion suggested by Plato, hinted in a single sentence that it might be a mistake to look for a planet in the interval between Mars and Jupiter, Professor Piazzi had already discovered the first of the asteroids on 1st January 1801. Apparently in August, when Hegel qualified, the news of the discovery had not yet reached him, but critics have made this luckless suggestion the ground of attack on a *prosaic* philosophy. The theses attached to this dissertation contained some characteristic paradoxes, e.g., that the syllogism is the principle of idealism, that a square is the law of nature, and a triangle of mind, &c.

Hegel's earliest lectures, in the winter of 1801-2, on logic and metaphysics were attended by about eleven students. At a later period, in 1804, we find him with a class of about thirty, lecturing on his whole system, but his average attendance was rather less. Besides philosophy, he once at least lectured on mathematics. As he taught, he was led to modify his original system, and notice after notice of his lectures promised a text-book of philosophy, which, however, failed to appear. Meanwhile, after the departure of Schelling from Jena in the middle of 1803, Hegel was left to work out his own views. Besides philosophical studies, where he now added Aristotle to Plato, he read Homer and the Greek tragedians, made extracts from books, attended lectures on physiology, and dabbled in other sciences. On his own representation at Weimar, he was in February 1805 made a professor extraordinary, and in July 1806 drew his first and only stipend—100 thalers. At Jena, though some of his hearers became devotedly attached to him, Hegel was not a popular lecturer any more than Kierkegaard. The ordinary student found Fines more intelligible.

Of the lectures of that period there still remain considerable notes. The language often had a theological tinge (never entirely absent), as when the "idea" was spoken of, or "the night of the divine mystery," or the dialectic of the absolute called the "course of the divine life." Still his view was growing clearer, and his difference from Schelling more palpable. Both Schelling and Hegel stand in a relation to art, but while the æsthetic model of Schelling was found in the contemporary world, where art was a special sphere and the artist a separate profession in no intimate connexion with the age and nation, the model of Hegel was found rather in those works of national art in which art is not a part of the common life but an aspect of it, and the artist is not a mere individual but a concentration of the passion and power of beauty in the whole community. "Such art," says Hegel, "is the common good and the work of all. Each generation hands it on beautified to the next, each has done something to give utterance to the universal thought. Those who are said to have genius have acquired some special aptitude by which they render the general shapes of the nation their own work, one in one point, another in another. What they produce is not their invention, but the invention of the whole nation, or rather, what they find is that the whole nation has found its true nature. Each, as it were, piles up his stone. So too does the artist. Somehow he has the good fortune to come last, and when he places his stone the arch stands self-supported." Hegel, as we have already seen, was fully aware of the change that was coming over the world. "A new epoch," he says, "has arisen. It seems as if the world spirit had now succeeded in freeing itself from all foreign objective existence, and finally apprehending itself as absolute mind."

These words come from lectures on the history of philosophy, which laid the foundation for his "Phenomenology of the Mind." The printing of this work (*Phänomenologie des Geistes*) began in 1806 at Bamberg, and the sheets were distributed, as they appeared, to a class where he treated the phenomenology as an introduction to logic. That comes he closed on the 18th September 1806, as follows:—"This, gentlemen, is speculative philosophy, so far as I have worked it out. We stand in a momentous time,—a seething mass, in which the mind has made a sudden bound, left its old shape behind, and is gaining a new. The whole bulk of our old ideas, the very bands of the world, are rent asunder, and collapse like a dream. Mind is preparing a new start. Philosophy, above all things, has to own and welcome such a start. While some in powerless resistance cling to the past, and the majority help, but unconsciously, to swell the numbers of its cortege, philosophy, recognizing it as the eternal, has to show it due honour."

Less than a month after, on the 14th October 1806, Napoleon was at Jena. But Hegel, like Goethe, felt no patriotic shudder at the victory, and in Prussia he saw only a corrupt and concealed bureaucracy. Writing to his friend Niehammer on the day before the battle, he speaks only with admiration of the "world soul," the emperor, and only with satisfaction of the probable overthrow of the badly-generalised and inefficient Prussians. The scholar's wish was to see the clouds of war pass away and leave thinkers to their peaceful work. His manuscripts were his main cure, and doubtful of the safety of his last despatch to Bamberg, and disturbed by the French soldiers in his lodgings, he hurried off, with the last pages of the *Phenomenology* in his pocket, to take refuge in the pro-rector's house. Hegel's fortunes were now at the lowest ebb. Without means and obliged to borrow from his friend Niehammer, he had no further hopes from the impoverished university. He had already tried to get away from Jena. In 1805, when several lectures left in consequence of diminished classes, he had written to Voss suggesting that his philosophy might find more congenial soil in Heidelberg, but the application bore no fruit. Now, however, it was necessary to do something. And so, when the proprietors of the *Bamberger Zeitung* were in want of an editor, Hegel, who had been named by Niehammer, at once accepted the offer, which involved a certain partnership in the concern. Early in 1807 he came to Bamberg, and stayed for about eighteen months. Of his editorial work there is little to tell, no leading articles appeared in his columns. Patriotic indignation against Napoleon, or interest in the fortunes of Prussia, were not wanted, and probably would not have been allowed. The editor was only expected to give his constituency news, and he did so with proper neutrality and from the best sources available. It was not a lofty or suitable vocation, and when a nomination to the rectorship of the Anglisten-gymnasium in Nuremberg was procured for Hegel, again by the agency of Niehammer, who was now in the education office at Munich, he was glad to go.

From December 1808 to August 1816 Hegel was school master at Bvaria, at this time under the direction of Montgolas, was modernising her institutions. The school system was reorganised by new regulations, which, *inter alia*, prescribed a training in philosophy as part of the gymnasial course. To this regulation (with which Hegel, however, was not agreed) we owe a series of lessons in the outlines of philosophy—ethical, logical, and psychological—in which Hegel drew up with great care, and many revisions. They were published in 1840 by Rosenkranz from Hegel's papers. Deviating somewhat from the official order, he began with the outlines of moral and religious doctrine, he then proceeded to psychology and a combined system of

logic and metaphysics, and ended with a general summary of the whole of philosophy.

As a teacher and master Hegel seems to have been fairly successful. He inspired confidence in his pupils, and maintained discipline without pedantic interference in their associations and sports. On the prize days at the close of the session, his addresses summing up the history of the school year discussed some topic of general interest. Five of these addresses are preserved. The first is an exposition of the advantages of a classical training, when it is not confined to mere points of grammar. "The perfection and grandeur of the master-works of Greek and Roman literature must be the intellectual bath, the secular baptism, which gives the first and unfading tone and tincture of taste and science." The school was mainly classical, yet at least one half of the time was given to arithmetic, history and geography, mathematics, physics, and preliminary philosophy. In another address, speaking of the introduction of military exercises at school, he says:—"These exercises, while not intended to withdraw the students from their more immediate duty, so far as they have any calling to it, still remind them of the possibility that every one, whatever rank in society he may belong to, may one day have to defend his country and his king, or help to that end. This duty, which is natural to all, was formerly recognized by every citizen, though whole ranks in the state have become strangers to the very idea of it."

On the 16th September 1811, in the summer vacation, Hegel married Marie von Tüchle. The young lady (twenty-two years younger than her bridegroom) belonged to Nuremberg, and seems to have been all that could be wished for in a wife. She brought her husband no fortune, but a cheerful heart. They seem to have had a happy if a frugal home, and a short excursion now and then was their chief dissipation. The husband kept a careful record of income and expenditure. That income at Nuremberg amounted to 1500 gulden (£180) and a house at Heidelberg, as professor, he received about the same sum, but at Berlin his regular stipend was about 3000 thalers (£300). Two sons were born to them, the eldest, Karl, born 7th June 1813, has since become eminent as a historian. The younger was named Immanuel, born on the 24th September 1816. Hegel's letters to his wife, written during his solitary holiday tours to Vienna, the Netherlands, and Paris, breathe of kindly and happy affection. Hegel, the tourist, recalling happy days spent together, confessing that, were it not because of his sense of duty as a traveller, he would rather be at home, dividing his time between his books and his wife, commenting on the shop windows at Vienna, describing the stray haire of the Fata Morgana ladies,—in a contrast to the professor of a profound philosophical system. But it shows that the enthusiasm which in his days of courtship moved him to verse had blossomed into a later age of domestic bliss.

The year after his marriage appeared the first two volumes of his *Wissenschaft der Logik*, and the work was completed by a third in 1816. This work, in which his system was for the first time presented in what, if we except a few minor alterations, was its ultimate shape, found some audience in the world, and from here and there came voices of encouragement. Sinclair, who in 1811 brought out three volumes on *Truth and Certainty*, Windischmann, subsequently professor at Bonn, Thüden, a Danish peasant farmer and votary of free thought, Berger, another Dane and philosopher, Van Ghert, an old pupil, now a Government official at Amsterdam,—these, as well as Knebel and Niehammer, corresponded with him during this period. Towards the close of his eighth session three professorships were almost simultaneously put within his reach,—at Erlangen, Berlin, and Heidelberg. The Prussian

offer expressed a doubt that his long absence from university teaching might have made him rusty, so he accepted the post at Heidelberg, whence Fries had just gone to Jena. He came to Heidelberg in October 1816. Though claimed with the neighbourhood, and plucked with the people, he was a little disappointed when only four hearers turned up for one of his courses. Others, however, on the encyclopedia of philosophy and the history of philosophy drew classes of twenty to thirty. While he was there, Cousin first made his acquaintance, but a more intimate relation dates from Berlin. Among his pupils was Hinrichs, who, originally a law student, became a philosophical disciple and wrote several works, to one of which, *Religion in its Inner Relation to Science*, Hegel wrote a rather important preface in 1823. The youngest of his hearers was an Estonian baron, Boris d'Ykull, who after serving in the Russian army came to Heidelberg to learn the wisdom of Hegel. But his books and his lectures were like obscurity to the town, who looked himself by Hegel's advice to some simpler life, in the shape of rudimentary knowledge, before he returned to the Hegelian system. The logic of his master, with whom he became intimate, was afterwards his constant companion in his travels.

At Heidelberg Hegel was also active in a literary way. In 1817 he brought out the *Encyclopedia of the Philosophical Sciences*, in outline, for use at his lectures. In its first form it was a small treatise of about 300 octavo pages, but in the second of 1827, and the third of 1830, it rapidly grew to twice the original bulk. It is the only exposition of the Hegelian system as a whole which we have direct from Hegel's own hand. Besides this work he wrote two reviews for the Heidelberg *Jahrbücher*—the first on Jacobi, the other a political pamphlet which called forth violent criticism. It was entitled a *Criticism on the Transactions of the Estates of Württemberg in 1816-16*. On the 16th March 1816 King Frederick of Württemberg, at a meeting of the estates of his kingdom, had before them the draft of a new constitution, in accordance with the resolutions of the congress of Vienna. Though an improvement on the old constitution, it was unacceptable to the estates, jealous of their old privileges and suspicious of the King's intentions. A decided majority demanded the restitution of their old laws, though the kingdom now included a large population to which the old rights were strange. Hegel in his essay, which was published at Stuttgart, strongly supported the royal proposals, and severely animadverted on the backwardness of the bureaucracy and the landed interests. In the main he was right, but he forgot too much the provocation they had received, the usurpations and selfishness of the governing family, and the unpopularity character of the king.

After two years at Heidelberg Hegel accepted the renewed offer of the chair of philosophy at Berlin, which had been kept vacant since the death of Fichte. The hopes which this offer raised of a position less precarious than that of a university teacher of philosophy were in one sense disappointed, for more than a professor Hegel never became. But his influence upon his pupils, and his solidarity with the Prussian Government, gave him a position such as few professors have held.

On the 25th October 1818 Hegel began his lectures at Berlin. "Our business and vocation," he said to his young hearers, "is to cherish the philosophical development of the substantial foundation (*s. e.* the state) which has renewed its youth and increased its strength." But Prussia had already proved false to the spirit of freedom which had armed the peoples against Napoleon. The enthusiasm which in the hands of Stein, Humboldt, and Scharnhorst had reformed the social, intellectual, and military organization of Prussia still smouldered, but hot-headed youth

ful politicians made it burst into fitful flames. Sober men were disgusted by the absurdities perpetrated at the Wartburg to celebrate the tricentenary of the Reformation. And though professors like Fries and Oken shared the behaviour of the students in this demonstration, and the assassination of Kotzebue in 1819 found admirers—such as the theological professor De Wetze, who spoke of it as a "beautiful sign of the time"—Stein spoke of the two professors as a pair of fools, and Niebuhr grew sad over the extravagances of the younger generation. Secret societies were formed or believed to be forming, and the Governments grew alarmed. In Prussia the reaction triumphed by the withdrawal of Humboldt in the last days of 1819, and the death of Hardenberg in 1822 was followed by a period of bureaucracy and conservatism.

It was in such an atmosphere that Hegel published the "Philosophy of Right" (*Grundlinien der Philosophie des Rechts*) in 1821. It is a combined system of moral and political philosophy, or a sociology dominated by the idea of the state. It turns away contemptuously and fiercely from the sentimental aspirations of reformers possessed by the democratic doctrine of the rights of the omnipotent nation. Fries is stigmatized as one of the "ingenuities of shallowness" who were bent on substituting a fanciful enthusiasm and friendship for the established order of the state. The disciplined philosopher, who had devoted himself to the task of comprehending the organism of the state, had no patience with feeble or more mercenary minds who recklessly laid hands on established ordinances, and set them aside where they contravened humanitarian sentiments. With the principle that whatever is real is rational, and whatever is rational is real, Hegel fancied that he had stopped the mouths of political critics and constitution-mongers. His theory was not a mere formulation of the Prussian state. Much that he construed as necessary to a state was wanting in Prussia, and some of the reforms already introduced did not find their place in his system. Yet, on the whole, he had taken his side with the Government. Alienists even expressed his satisfaction with the book. In his disgust at the crude conceptions of the enthusiasts, who had hoped that the war of liberation might end in a realm of internal liberty, Hegel had forgotten his own youthful vows recorded in verse to Holderlin, "never, never to live in peace with the ordinance which regulates feeling and opinion." And yet if we look deeper we see that this is no worship of existing powers. It is rather due to an overpowering sense of the value of organization,—a sense that liberty can never be discovered from order, that a vital interconnection between all the parts of the body politic is the source of all good, so that while he can find nothing but brute weight in an organized public, he can compare the royal person in his ideal form of constitutional monarchy to the dot upon the letter. A keen sense of how much is at stake in any alteration breeds suspicion of every reform.

During his thirteen years at Berlin Hegel's whole soul seems to have been in his lectures. Between 1823 and 1827 his activity reached its maximum. His notes were subjected to perpetual revisions and additions. We can form an idea of them from the shape in which they appear in his published writings. Those on *Aesthetics*, on the *Philosophy of Religion*, on the *Philosophy of History*, and on the *History of Philosophy*, have been published by his editors, mainly from the notes of his students, under their separate heads, while those on logic, psychology, and the philosophy of nature are appended in the form of illustrative and explanatory notes to the sections of his *Encyclopædie*. During these years hundreds of hearers from all parts of Germany, and from beyond the Fatherland, came under his influence. His fame was carried abroad by eager

or intelligent disciples At Berlin Henning served to prepare the intending disciple for fuller initiation by the master himself Gans and Hotho carried the method into special spheres of inquiry At Halle Hinrichs maintained the standard of Hegelianism amid the opposition or indifference of his colleagues

Hegel himself in his class room was neither imposing nor fascinating You saw a plain, old-fashioned face, without life or lustre—a figure which had never looked young, and was now bent and prematurely aged, the furrowed face bore witness to concentrated thought Sitting with his snuff-box before him, and his head bent down, he looked ill at ease, and while still speaking kept turning the folios of his notes His utterance was interrupted by frequent humming and coughing, every word and every sentence came out with a struggle, and if, when the right word seemed as if it would never come and no progress appeared to be making, the listener for a moment ceased to listen, he found when attention returned that the lecture had reached a new stage, and the connexion was lost And the style of these utterances was no less irregular Sometimes in the plainest narrative the lecturer would be specially awkward, while in the abstrusest passages he seemed specially at home, rose into a natural eloquence, and carried away the hearer by the splendour of his diction

Three courses of lectures are especially the product of his Berlin period: those on æsthetics, the philosophy of religion, and the philosophy of history In the years preceding the revolution of 1830, public interest, excluded from political life, turned to theatres, concert rooms, and picture galleries At these Hegel became a frequent and appreciative visitor He even made extracts from the art notes in the newspapers In his holiday excursions, the interest in the fine arts is prominent, and more than once takes him out of his way to see some old painting His letters to his wife are full of such topics A visit to Vienna in 1824 presents him spending every moment at the Italian opera, the ballet, and the picture galleries In Paris, in 1827, curiously enough, he heard Charles Kemble and an English company play Shakespeare This familiarity with the actual facts of art, though neither very deep nor very historical, gave an unusual freshness to his lectures on æsthetics, which, as put together from the notes of 1820, 1823, 1826, are in many ways the most successful of his efforts

The lectures on the philosophy of religion are another application of his method to an important sphere of human interests Shortly before his death he prepared for the press a course of lectures on the proofs for the existence of God In his lectures on religion he dealt with Christianity, as in his philosophy of morals he had regarded the state On one hand he turned his weapons against the rationalistic school, who reduced religion to the medium compatible with an ordinary worldly mind On the other hand he criticized the school of Schleiermacher, who elevated feeling to a place in religion above systematic theology His middle way attempts to show that the dogmatic creed is the rational development of what was implicit in religious feeling To do so, of course, philosophy becomes the interpreter and the superior To the new school of Hegensteinberg, which regarded Revelation itself as supreme, such interpretation was an abomination

A Hegelian school began to gather The flock included intelligent pupils who applied the method in different provinces of speculation, empty-headed imitators who repeated the catchwords of the new dialectic, and romantic natures who turned philosophy into lyric measures Opposition and criticism, which were not wanting, only served to define more precisely the adherents of the new doctrine The master himself grew more and more into a belief in his own doctrine as the one truth for the world The system

had grown gradually with him, and had assimilated intellectual nutriment from every hand so as to make all history and all knowledge bear witness to its truth He was in harmony with the Government, and his followers were on the winning side Though he had soon resigned all direct official connexion with the schools of Brandenburg, his real influence in Prussia was considerable, and as usual was largely exaggerated in popular estimate In the narrower circle of his friends his birthdays were the signal for congratulatory verses In 1826 a formal festival was got up by some of his admirers, one of whom, Heider, spoke of his categories as new gods, and his was presented with much poetry and a silver mug In 1830 the students struck a medal in his honour, and in 1831 he was decorated by an order from the king In 1830 he was rector of the university, and on the tricentenary of the Augsburg Confession in that year, he took the opportunity in his speech on the occasion to charge the Catholic Church with regarding the virtues of the pagan world as brilliant vices, and giving the crown of perfection to poverty, continence, and obedience

One of the last literary undertakings in which he took part was to give his support to Gans and Varnhagen von Ense in the establishment of the Berlin *Jahrbücher für Wissenschaftliche Kritik* The aim of this journal was to give a critical account, certified by the names of the contributors, of the more important literary and philosophical productions of the time, in relation to the general progress of knowledge The journal was not solely in the Hegelian interest, and more than once, when Hegel attempted to domineer over the other editors, he was met by vehement and vigorous opposition It gave him besides a deal of trouble with sanguine authors, who looked forward to a favourable word from him as a passport to fame

The revolution of 1830 was a great blow to him, as to many other Germans, and the prospect of democratic advances almost made him ill His last literary work was an essay on the English Reform Bill of 1831, the first part of which appeared in the *Preussische Staatszeitung* It contains primarily a careful consideration of the effects likely to come from the alterations in the electoral franchise, in relation, first, to the character of the new members of parliament, and secondly, to the measures which they may introduce In the latter connexion he enlarges on several points where England had done less than many Continental states for the abolition of monopolies and abuses Surveying with such intelligence of English circumstances the questions connected with landed property, with the game laws, the poor, the Established Church, especially in Ireland, Hegel throws grave doubt on the legislative capacity of the English parliament as compared with the power of renovation and reform manifested in the more advanced states of western Europe Much of this essay, unfortunately, has not become antiquated as a critique on the social state of Britain

In 1831 the cholera had first entered Europe Hegel and his family retired for the summer to a lodging in the suburbs, and there he finished the revision of the first part of his *Science of Logic* On the commencement of the winter season, however, he returned to his house in the Kupfergraben On this occasion an unseemly altercation occurred between him and his friend Gans, who in his notice of lectures on jurisprudence had recommended Hegel's *Philosophy of Right* Hegel, indignant at what he deemed patronage, asked Gans in a rough manner to withdraw the notice On Friday 11th November Hegel had lectured as usual On Sunday he had a violent attack of cholera, and on Monday, the 14th November 1831, he was dead He was buried on the spot he had wished for himself, between Fichte and Solger

final, free, and mutually not penetrable in every part,—the spirit in its scientific scientific life, before custom had produced a natural world, and thought had risen to independent existence in the social organism. Thought in this primary form, when in all its parts completed, is what Hegel calls the "idea." But the idea, though fundamentally, is in another sense final, in the process of the world. It only appears in consciousness as the crowning development of the mind. Only with philosophy does thought become fully conscious of itself in its own development. Accordingly the history of philosophy is the presupposition of logic, or the three sciences of philosophy form a circle.

The exposition of constitution of the "idea" is the work of the Logic. As the totality of the idea into three parts, so every part of the system follows the triadic law. Every truth, every reality, has three aspects or stages, it is the unification of two contradictory elements, of two partial aspects of truth which are not mutually contrary, like black and white, but antithetical, like same and different. The first step is a preliminary affirmation and unification, the second a negation and differentiation, the third a final synthesis. For example, the seed of the plant is an initial unity of life, while when it is placed in its proper soil and differentiation into its constituent parts, and yet in virtue of its vital unity keeps these divergent elements together, and insures as the plant with its members in organic union. Or again, the process of scientific induction is a triadic chain, the original hypothesis (the first unification of the fact) comes to melt away when confronted with opposite facts, and yet no scientific progress is possible unless the stimulus of the original unification is strong enough to clear the discordant facts and establish a reunification. Thesis, antithesis, and synthesis, a Fichtean formula, is generalized by Hegel into the perpetual law of thought.

In what we may call their psychological aspect these three stages are known as the abstract stage, that of understanding (*Verstand*), the dialectical stage, or that of negative reason, and the speculative stage, or that of positive reason (*Reason*). The first of these attitudes taken alone is strong enough to clear the discordant facts and establish a reunification. Thesis, antithesis, and synthesis, a Fichtean formula, is generalized by Hegel into the perpetual law of thought. In what we may call their psychological aspect these three stages are known as the abstract stage, that of understanding (*Verstand*), the dialectical stage, or that of negative reason, and the speculative stage, or that of positive reason (*Reason*). The first of these attitudes taken alone is strong enough to clear the discordant facts and establish a reunification. Thesis, antithesis, and synthesis, a Fichtean formula, is generalized by Hegel into the perpetual law of thought. In what we may call their psychological aspect these three stages are known as the abstract stage, that of understanding (*Verstand*), the dialectical stage, or that of negative reason, and the speculative stage, or that of positive reason (*Reason*). The first of these attitudes taken alone is strong enough to clear the discordant facts and establish a reunification. Thesis, antithesis, and synthesis, a Fichtean formula, is generalized by Hegel into the perpetual law of thought.

This introduction of the absolute became a stumbling-block to Fichte and other members of the "Left." They rejected as an illegitimate interpolation into the eternal subject of development, and instead of one continuing process as the subject of the process, they held in the logic the absolute is defined, assumed only a series of ideas, products of philosophic activity. They denied the philosophical value of the logical forms,—the development of these forms being in their opinion the work of human thinkers, not a self-revelation. Thus they made man the creator of the absolute. But

with this modification on the system thought necessarily followed, a more logical sense could not create truth. And thus the initial universe became the real starting-point. Thought became only the result of organic conditions—subjective and human,—and the system of Hegel is no longer an idealization of religion, but a naturalistic theory with a prominent and peculiar logic.

The logic of Hegel is the only rival to the logic of Aristotle that Aristotle did for the theory of demonstrative reasoning. Hegel attempted to do for the whole of human knowledge what logic is in enumeration of the forms or categories by which our experience exists. It traced out Kant's doctrine of the categories as a *method* of induction, principles, but removed the limitations which Kant placed upon any constitutive use except in mathematics and experience. According to Hegel the terms in which thought exhibits itself are a system of their own, with laws and relations which happen in a less obvious shape in the theories of nature and mathematics. Not only their restricted to deal with numbers which Kant obtained by manipulating the content subdivision of judgments. But all forms by which thought holds sensation in unity (the formative or synthetic elements of language) had their place assigned in a system whose one law is up to and passes over into another.

The fact which ordinary thought ignores, and of which ordinary logic takes no account, is the presence of gradation and continuity in the world. The general terms of language simplify the universe by reducing its variety of individuals to a few forms, none of which exist simply and perfectly. The method of the understanding is to divide and thus to give a separate reality to what it thus distinguishes. It is part of Hegel's plan to remedy this one-sided character of thought, by laying bare the gradations of ideas. He lays special stress on the point that the logical ideas of nature and mind are not abstract and unchangeable, but are in a sense fluid, and in their oppositions that existences meet, and that in every true and concrete idea there is a coincidence of opposites.

The beginning of the logic is an illustration of this. The unity of thought is being, we cannot think less about anything than when we merely say that it is. Being—the abstract—"is"—is nothing definite, and nothing at least is. Being and not being is thus declared identical,—a proposition which this unqualified statement seems to most people a stumbling block at the very door of the system. Instead of the unity "is" which is as yet nothing, we should rather say "becomes," and "is" becomes "is" implies "something," we have a movement, a becoming, which in the next stage of development becomes "one." And in this way we pass on to the quantitative aspects of being.

It is impossible to give a brief account of the long development of thought, especially in the course of the domains under fire in the details. The logical idea is treated under the three heads of being (*Sein*), essence (*Wesen*), and notion (*Begriff*). The terms treated under the first head, in addition to those already mentioned, are the abstract principles of quantity and number, and their application in measure to determine the limits of being. Under the title of essence we discussed those parts of speculative terms which are naturally employed in the expression of the world,—such as law and causation, cause and effect, reason and consequence, substance and attribute. Under the head of notion we considered, firstly, the subjective forms of conception, judgment, and syllogism; secondly, their restriction in objects in which they are objectively or teleologically constituted; and thirdly, the idea of life, and next of essence, as the complete interpenetration of thought and objectivity. The third part of logic, entitled *Logic*, is devoted to those topics mainly treated in logic before, but which extend the province of logic in the ordinary sense is excluded. The first is to divisions—the "objective logic"—is what is usually called metaphysics.

The characteristics of the system, and one impossible to exclude in a summary, is the gradual way in which idea is linked to idea so as to make the division into chapters only an arrangement of convenience. The judgment is completed in the syllogism, the syllogism form as the perfection of subjective thought, and the syllogism is itself appears embodied in a mechanical system, and the teleological object, in which the members are as means and end, leads up to the idea of life, where the end means and means are indivisibly tied together. In none of these transitions may we be misstruck and feared, it is apparent that the linear development from "being" to the "idea" is got by transforming into a logical order the sentences that have roughly, provided in philosophy from the Platonic, cases might be questioned, and the meaning of the play upon words, and it may often be doubted whether certain ideas do not involve extra-logical considerations. The order of the categories is in the main outlined first, but in the main it is much dependent upon the philosophy of nature, which is the gap in the logical ideas, with little guidance from the data of experience, and to assign to the stages of development names which occasionally deal hardly with language. The next of Hegel to be mentioned is that of our forms of thought, to have arranged them in the order of their comparative capacity to give a satisfactory expression to truth

The lectures on the Philosophy of Art stay largely into the next sphere and dwell with art on the close connection of art and religion, and the discussion of the decadence and use of religions, of the æsthetic qualities of Christ in legend, of the age of chivalry, &c., in the *Æsthetik* which was afterwards published.

The lectures on the Philosophy of Religion, though unequal in their composition and belonging to different dates, strive to exhibit the vital connexion of the system with Christianity. Religion, like art, is inferior to philosophy, an event of the humanly-interesting man and the absolute. In it the absolute exists in the poetry and music of the heart, in the universality of feeling. Hegel after expounding the nature of religion proceeds on to discuss its historical history, but in the immediate end of religious sense, falls into several mistakes. At the bottom of the scale of nature-worship he places the religion of society. The gradations which follow are hypothetical with some inconsistency amongst the religions of the East. With the Eastern religion of light and the Egyptian of enigmas we pass to those fields where Goethe takes the form of a spiritual individuality, e.g., to the Indian religion (of sublimity), the Greek (of beauty), and the Roman (of abnegation). Last comes absolute religion, in which the mystery of the reconciliation between God and man is an open doctrine. This is Christianity, in which God is a Trinity, because He is a spirit. The revelation of His truth is the subject of the Christian Scriptures. For the Son of God, in the immediate aspect, is the finite world of nature and man, which is felt as being at one with its Father as originally in an attitude of estangement. The history of Christ is the visible reconciliation between nature and the eternal. With the death of Christ this union, ceasing to be a mere fact, becomes a vital idea—the Spirit of God which dwells in the Christian community.

The lecture on the History of Philosophy deal despatchedly with the various epochs, and in some parts date from the beginning of Hegel's career. In trying to subject history to the mode of logic they sometimes misrepresent the filiation of ideas. But they treat the history of philosophy as a scientific study. They showed that a philosophical theory is not a product of a man, but the product of its age determined by its antecedents and environments, and handing on its results to the future.

For ten years after Hegel's death his system remained the foremost intellectual phenomenon in the time of Germany. Humboldt, Hegel, and Heide, who have been already alluded to, the most prominent of his immediate disciples as Gable, whose *Principles of Logic* is a good introduction to Hegel, and L. Michelet, one of the most able of Hegelians, in 1870, on the centenary of Hegel, gave a summary of the system, Düb and Michelet, the two theologians, and Jorschel, whose *Aphorisms über nicht-Verneinte und absolute Prozesse* is a valuable review from Hegel. In addition, where the school went some distinction, are the names of Schaller, Rosenkranz, and Vissler. Karl Rosenkranz, the literary champion of the system, has just ended a life devoted to its exposition, but many still teach in its spirit at Halle, as does Ernst Bruns at Jena. The last two have specially distinguished themselves by their histories of modern philosophy. With Michelet they form the more orthodox and conservative section of the school. The opponents to it are, first, the *Zeitungsphilosophen*, and the *Zeitschrift für Philosophie*, founded in 1837 by the younger Fichte with the help of Wesse, while Benke and other followers of Heiberg vigorously attacked the metaphysics and psychology. But the most notable outgrowth is that of 1870, the *Zeitschrift für kritische und historisch-critische Schule* of Follenbach, Bruno Baur, and Ruge. While Hegel had vindicated God as the subject of metaphysics, maintained the continuance of philosophy and theology, and devoted the state to sovereignty in effecting the last divine end of the system, opposed its alleged pantheism or atheistic tendencies, and insisted the supremacy of the individual in morals. To discuss the evolution of Hegelianism in this direction would almost be to write the history of modern German philosophy up to 1866. Hegelianism has now ceased to exist as an official system in Germany, though its spirit and method have leavened the whole mass of philosophic thought. Out of Germany, besides occasional admirers and disciples, it has effected a considerable amount of general currency. In England it has stimulated philosophical thought, and probably suggested the correction of some national limitations, but few if any profess to accept the system in its integrity. Professor Voss of Naples is perhaps the most enthusiastic advocate on the Continent, whilst the *Journal of Speculative Philosophy* upholds its banner in America.

Philosophy.—Shortly after Hegel's death his collected works were published by a number of his friends, who continued for the purpose. They appeared in eighteen volumes in 1832, and a second edition came out about twelve years later. Volumes I–viii contain the works published by himself, the remainder were made up of his lecture on the Philosophy of Nature, *Æsthetik*, the Philosophy of Religion, and the History of Philosophy, besides some essays and reviews, with a few of his letters, and the Philosophical Prolegomena.

For his life see Rosenkranz, *Leben Hegels*, Berlin, 1844; Haym,

Hegel und seine Zeit, Berlin, 1857; Kostlin, *Hegel als Philosophischer, politischer, und nationaler Denker*, Tübingen, 1870; Roschkin, *Hegel als Deutsches Nationalphilosoph*, Berlin, 1870; and his *Neue Studien*, vol. iv, Berlin, 1878.

For the philosophy, see *Haym's Leben und Zeit*, vol. iv, Berlin, 1867; Haym (see above) *Traktat über (in Logische Untersuchungen)*, Kryn (*Metaphysische Untersuchungen*), and C. H. Harnack (*Über die Logische Frage*, and other works) are noticeable as modern critics. Note has been translated the *Encyclopædia* into French, with notes, Barand, the *Æsthetik* in English by Stirling's *Secret of Hegel*, 2 vols., London, 1865, contains a translation of the beginning of the *Phænomenologie des Geistes*, the "Logic" from the *Encyclopædia* has been translated with polemics by W. Wallace, Gifford, 1874, and large portions have been translated in the *American Journal of Speculative Philosophy*—especially by its energetic editor, W. T. Harris. (W. W.)

HEIBERG, JOHAN LUDVIG (1791–1860), Danish poet and critic, was the son of the political writer Peter Andreas Heiberg, and of the famous novelist, afterwards the Baroness Gyldenboug-Ehrensvärd. He was born at Copenhagen, December 14, 1791. In 1800 his father was exiled, and he was taken by Rinkbeek and his excellent wife into their house at Bakkehuset. They found him, however, very difficult to manage, and about 1802 sent him back to his own family. His mother's marriage being by a state decree annulled, she married the Swedish baron Gyldenboug-Ehrensvärd, keeping up, however, friendly correspondence with her first husband in Paris. In 1805 she deserts, in one of these letters, the brilliant precocity of the young Johan. The latter proceeded to the university of Copenhagen in 1809. It was not needful that he should earn his bread, and accordingly his mother indulged for many years his extraordinary thirst for knowledge. In 1812 he visited Paris, and made some long stay in Stockholm, afterwards sent to his mother from Upsala the first important poem which he composed, *Hjemkomsten* ("The Return Home"), a piece of remarkable strength and brightness. In 1813 his first publication appeared, a romantic drama for children, entitled *The Theatre for Marionettes*. This was followed by *Christmas Jokes and New Year's Truths* in 1816, *The Imitation of Psyche*, 1817, and *The Prophecy of Tycho Brahe*. These works attracted attention at a time when Baggensen, Oehlenschläger, and Ingemann possessed the popular ear, and were understood at once to be the opening of a great career. In 1817 Heiberg took his degree, and in 1819 went abroad with a grant from Government. He proceeded to Paris, and spent the next three years there, under his father's roof. In 1822 he published his drama of *Mina*, and was made professor of the Danish language at the university of Kiel. At this town he delivered a course of lectures, comparing the Scandinavian mythology as found in the *Edda* with the poems of Oehlenschläger. These lectures were published in Geiman in 1827. In 1825 Heiberg came back to Copenhagen for the purpose of introducing the *vaudeville* on the Danish stage. Meanwhile he was producing dramatic work of a more serious kind. In 1828 he brought out the national drama of *Esteren*, in 1835 the comedy of *The Elbow*, and in 1838 *Papa Margareta*. In 1841 Heiberg published a volume of *New Poems*, containing "A Soul after Death," which is perhaps his masterpiece, "The Newly Wedded Pair," and other pieces. All this time he had been busily engaged in editing the famous journal, *The Copenhagen Flying Post*, which he founded in 1827 and continued until 1837. In 1831 he married Johanne Louise Piesges, the greatest actress that Scandinavia has produced. Heiberg's scathing satires at last began to make him very unpopular, and this antipathy reached its height when, in 1845, he published

¹ He composed a great number of *vaudeville*, of which the best known are *King Solomon and George Hættelær*, 1826; *April Poole*, 1836; *A Story in Rosemary Garden*, 1837; *Kyoko Tuskers*, 1831; *The Danish Poet*, 1838; *No*, 1838; *Yes*, 1839; and *Emily's Baking Heart*, 1840.

his little malicious drama of *The Nut Crackers*. Notwithstanding this he retained in 1847 the responsible post of director of the national theatre, for which indeed he was more eminently fitted than any other living person. He filled it for seven years, working with great zeal and conscientiousness, but was forced by intrigues from without to resign it in 1854. His health was much disturbed by these attacks, and he retired into private life. Heiberg died at Bønderup, near Ringsted, on the 25th of August 1860.

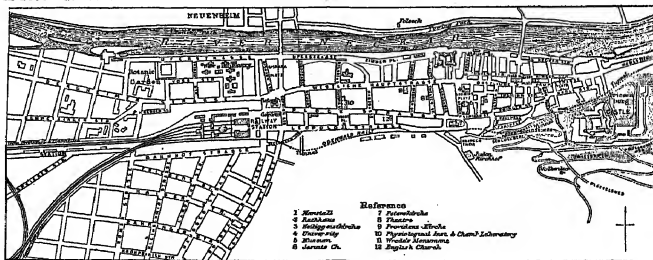

It has been said that "the average cultivated Dane nowadays is very much what Heiberg has made him." His influence upon taste and critical opinion was greater than that of any writer of his time, and can only be compared with that of Holberg in the 18th century. Most of the poets of the Romantic movement in Denmark were very grave and serious; Heiberg added the element of humour, elegance, and irony to the dignity of Oehlenschläger, the pathos of Ingemann, and the passion of Hertz. His versification was refined and exact, and his very best pieces are those in which he mingles rich lyrical expression with what is satirical or purely ludicrous. The works of Heiberg were collected, in 11 vols., in 1861-63.

HEIDE, a town of Prussia, chief town of the circle of North Ditmarsh, provinces of Schleswig-Holstein, is situated on a small plateau which stands between the marshes and bogs bordering the North Sea, 35 miles N.N.W. of Glückstadt. It is the seat of a provincial office, a court of justice, and a head tax office, and possesses tobacco and cigar manufactories, a tannery, and a rope work. Heide in 1447 became the capital of the Ditmarsh peasant republic, but on the 13th June 1559 it was the scene of the complete defeat of the peasant forces by the Danes and the duke of Schleswig-Holstein. The population in 1875 was 6772.

HEIDEGGER, JOHN HENRY (1633-1698), theologian, was born at Dikentschwil, in the canton of Zurich, Switzerland, on July 1, 1633. He began his studies in his native country, and completed them at Marburg and Heidelberg. Becoming doctor of philosophy at the latter university, he soon afterwards was appointed professor extraordinarius of Hebrew, and later of philosophy. From Heidelberg he was in 1659 summoned to Steinfurt to fill the chair of theology and ecclesiastical history, and in the same year he became doctor of theology of Heidelberg. In 1660 he revisited Switzerland; and, after marrying, he travelled in the following year over Holland. The war at this time having dispersed the students from Steinfurt, Heidegger returned in 1665 to Zurich, where he was immediately elected professor of moral philosophy. Two years later he succeeded Hottinger in the chair of theology, which he occupied till his death, January 15, 1698. Heidegger was the principal author of the *Formula Consensus Helvetica* in 1675, which was designed to unite the Swiss Reformed churches, but had an opposite effect.

His writings are largely controversial, and are in great part levelled against the Roman Catholic Church. The chief are *De Historia sacra Patriarcharum Excerptationes selectae*, 1687-1671; *Dissertatio de Peregrinationibus Religiosis*, 1670; *De Ratione Studiorum, quatuor aures*, &c., 1672; *Historia Paganus*, 1684; *Tractatus Conciliis Tridentinis*, 1690; *Excerptationes Biblicae*, 1700, with a life of the author prefixed; *Corpus Theologicum Christianum*, 1700; and lives of Hottinger, 1698, and Fabricius, 1698. His autobiography appeared in 1698, under the title *Historia Vita J. H. Heideggeri*.

HEIDELBERG, a German university city in the Baden circle and jurisdiction of the same name, lies in 49° 24' N. lat. and 8° 41' 32" E. long., at the foot of the Castlehill, a spur of the Königstuhl on the south bank of the Neckar, about 12 miles from the junction of that river with the Rhine. The situation of the town is one of romantic beauty.

Plan of Heidelberg.

Placed at the opening of the winding Neckar valley, it has behind it and before it lofty hills covered with vineyards and forests. Between these the Neckar rushes swiftly along. To the left the country opens out into the broad Rhine plain, cultivated like a garden, and bounded by distant and hardly perceptible mountains. The town primarily consists of one long narrow street, the Hauptstrasse, which begins near the station of the Main-Neckar railway on the west, and runs parallel to the river with continuations for a distance of about 2 miles to the Karlsthor (where there is a smaller station) on the east. To the south of this the Anlage, a pleasant promenade flanked with fine houses and gardens, leads directly from the chief station to the centre of the town. A number of smaller streets run up from the river, intersecting the

Hauptstrasse at right angles. On the other side of the Neckar the Heiligenberg, a vine-clad hill wooded towards the summit, crowned with the ruins of an old chapel, rises abruptly from the river bank. About half-way up the hill the Philosophenweg, a famous road, runs from the Hirschgasse opposite the Karlsthor to the suburb of Neuenheim, opposite the railway station. At this point the Neckar valley ceases, and the river flows slowly onward in the almost level Rhine plain. Of late years the town has grown very much towards the west end on both sides of the river. The additions have been almost entirely of the better class of houses.

Of the churches the chief are the Peterskirche (founded before 1392), where Jerome of Prague in 1400 expounded the Reformed doctrines; the Heiliggeistkirche,

erected at the beginning of the 15th century, of which the nave is used for Protestant, the choir for Old Catholic worship; and the Jesuitenkirche, with sumptuously decorated interior. All these are built in the Gothic style. The Rathaus, the museum, and the university (1712) are large but common-place erections. Two handsome bridges cross the Neckar. That to the east, opposite the castle (built 1788), is adorned with a gateway, and with statues of Minerva and the elector Charles Theodore of the palatinate; the other (built 1877) unites Heidelberg and Neuenheim. In the west part of the town there is a bronze statue of Field-Marshal Prince Wrede (1767-1838), erected in 1860 by Louis I., king of Bavaria. The chief building at Heidelberg, and indeed its chief attraction for strangers, is the famous castle which overhangs the west part of the town. It is situated on the Castlehill, more properly called the Jottenbühl, 330 feet above the Neckar. Though now a ruin, yet its extent, its magnificence, its beautiful situation, its interesting history, render it by far the most noteworthy, as it certainly is the grandest and largest, of the old castles

Ground-Plan of Heidelberg Castle.

of Germany. It was begun about the end of the 13th century. Elector Rupert greatly improved it, and erected the Rupert's building in the early part of the 15th century; succeeding electors of the palatinate did much for it, especially Frederick V., the unfortunate king of Bohemia. It suffered greatly during the Thirty Years' War, but was restored by Charles Louis (1650-1680). It was dismantled by the French in 1689, and again in 1693. In 1764 it was struck by lightning and its destruction completed. The castle as it at present stands is a square edifice formed of several distinct structures built round a large court-yard; the entrance is on the south side. The court-yard contains a fountain adorned with four granite pillars brought from Charlemagne's palace at Ingelheim. The chief parts of the castle are Rupert's building (about 1400) on the left; Otto Henry's building (1556) on the right, "the finest example of Renaissance architecture in Germany," a lofty building of which the front is richly decorated; Frederick's building (1601), the finest part, forming the northern portion of the whole, and adorned

with a large number of imposing statues. Within this is the chapel, and behind it the Altan (1610), or castle balcony, which directly overhangs the town and from which the finest of Heidelberg views is obtained. The castle contains an interesting antiquarian museum² formed by the Count Gvaimberg, and the celebrated Great Tun, which was built in 1751, but has been only used on one or two occasions. Its capacity is 49,000 gallons. There is a castle garden, spacious and well laid out.

The university of Heidelberg is the oldest in the German kingdom. It was founded in 1386 by the elector Rupert, but it was not till 1386, when it obtained papal sanction, that its real life begins. It was constructed after the type of Paris, had four faculties, and possessed numerous privileges. Marselin von Inghau was its first rector. Frederick the Victorious, Philip the Upright, and Louis V. respectively cherished it. Otto Henry gave it a new organization, further endowed it, and founded the library. At the Reformation it became a stronghold of Protestant learning. The famous Heidelberg catechism was drawn up by its theologians. Then the tide turned. Damaged by the Thirty Years' War, it led a struggling existence for a century and a half. A large portion of its remaining endowments were cut off by the peace of Lunenburg (1693). In 1698 however the elector Charles Frederick raised it anew, and reconstituted it under the name of "Ruperto-Carolina." At present (1880) it has 38 ordinary and 26 extraordinary professors. The students number about 500 in winter, and from 800 to 900 in summer. A very large proportion are English and Americans. The library was first kept in the choir of the Heiliggeistkirche, and then consisted of 3500 MSS. In 1623 it was sent to Rome by Tilly, and stored as Bibliotheca Palatina in the Vatican. It was afterwards taken to Turin, and in 1815 was restored to Heidelberg. In 1703 the new library was founded; it has now nearly 300,000 volumes, besides many valuable MSS. Among the other university institutions are the academic hospital, the maternity hospital, the physiological institution, the chemical laboratory, and the zoological museum.

The other educational foundations are a gymnasium and a burgher and a real school. There is a small theatre (closed during the summer months) and a Kunstverein. The manufactures of Heidelberg are unimportant. The inhabitants chiefly support themselves by supplying the wants of a large and increasing body of foreign permanent residents, of the considerable body of tourists who during the summer pass through the town, and of the university students. The population of the town and outlying suburbs was 19,988 in 1871, and 22,334 (or including Neuenheim, 23,618) in 1875. About one-third are Catholics. The town is well lighted, and is supplied with excellent water from the Wolfsbrunnen.

Heidelberg at an early period was a fief of the bishop of Worms, but the rulers of the palatinate came more and more to reside there, till Count Otto of Wittelsbach (1292-1298) made it the capital of the palatinate, and this it continued to be for nearly six centuries. As Heidelberg was one of the great centres of the Reformed faith, it suffered severely in the Thirty Years' War. In 1622 it was sacked by Tilly, and in 1689 was taken by the Swedes. In 1694 it was beleaguered by the Bavarians. In 1685 it was occupied by the Imperial forces under Gallia. At the peace of Westphalia (1648) Charles Louis, son of Frederick V., was restored, and he did much to raise the castle, the university, and the town. In 1688, and again in 1693, it was sacked by the French. On the last occasion, so thorough was the work of destruction that only one house—a quaintly decorated mansion in the Macklaystrasse now used as an inn—escaped. In 1780 Charles Philip removed his court to Mannheim, and in 1803 the town became part of the grand duchy of Baden. On 6th March 1848 was held the famous Heidelberg assembly, at which steps were taken that led to the German revolution of that year.

² This museum was acquired by the town in 1879.

Of the numerous topographical works on Heidelberg, those of Fickler (1833) and Oncken (2d ed., 1874) may be mentioned. The *Wegweiser durch Heidelberg* (1876) supplies a brief and most popular account. The university annals are told in Heint's *Geschichte des Universitäts-Heidelbergs* (2 vols., 1833-34), and the very interesting history of the library in Wilken's *Geschichte der Bildung, Erziehung, und Entwicklung des alten Heidelberger Buchsammlungs* (1817), and in Rühnd's *Zur Geschichte des alten nach Rom eingeführten Bibliothek zu Heidelberg*, Leip., 1840. The *Heidelberger Jahrbücher* (1817-73) contain a mass of interesting and important information as to the history of the town and castle. (P. W.)

HEIDELOFF, KARL ALEXANDER VON (1788-1866), a German architect, was the son of Victor Peter Heideloff, a painter of some reputation, and was born at Stuttgart 2d February 1788. He studied at the art academy of his native town, and after following the profession of an architect for some time at Coburg was in 1818 appointed city architect at Nuremberg. In 1822 he became professor at the polytechnic school, and some years later he was chosen conservator of the monuments of art. Heideloff devoted his chief attention to the Gothic style of architecture, and the buildings restored and erected by him at Nuremberg and in its neighbourhood attest both his original skill and his purity of taste. He also achieved some success as an historical painter. He died at Hanau 28th September 1866.

Among his writings on architecture are *Die Lehre von den Bauformen*, 1837, *Der Kleins Fingeln*, 1832, *Nuremberg Baudekmale des Vorzeit*, 1838-43, and *Die Ornamentik des Mittelalters*, 1838-42.

HEILBRONN, a town of Württemberg, in the circle of the Neckar, is situated in a pleasant and fruitful valley on the Neckar, and at the junction of several railways, 26 miles N. of Stuttgart. It is the seat of a circle court, a jury court, a superior tribunal, a head tax office, and a chamber of commerce. In the older part of the town the streets are narrow, and it contains a number of high timbered houses with quaintly adorned gables. The old fortifications have now been demolished, and their site is occupied by promenades, outside of which are the more modern parts of the town with wide streets and many handsome buildings. The principal public buildings are the church of St Kilian, in the Gothic and Renaissance styles, begun in 1019 and completed in 1529, with an elegant tower 210 feet high, a beautiful choir, and a finely carved altar; the town-house, founded in 1540, and possessing a collection of interesting documents; the house of the Teutonic knights, now used as barracks; the Catholic church of St Joseph, the tower on the Neckar, in which Gutz von Berlichingen was confined in 1525; the synagogue, the prison, and the hospital. The educational establishments include a gymnasium, a real-school of the second order, an agricultural school, and a female school of industry. The town in a commercial point of view is the most important in Württemberg, and possesses an immense variety of manufactures, of which the principal are gold, silver, steel, and iron wares, machines, sugar of lead, white lead, vinegar, beer, ear-de machines, cigars, tobacco, soap, oil, cement, sulphuric acid, tartaric acid, artificial manure, glass, soda, tapestry, thread, and cloth. Grapes, fruit, vegetables, and flowering shrubs are largely grown in the neighbourhood, and there are large quarries for sandstone and gypsum. By means of the Neckar a considerable trade is carried on in wood, bark, leather, agricultural produce, fruit, and cattle. The population in 1875 was 21,909.

Heilbronn occupies the site of an old Roman settlement. Its name—originally *Heilbrunn* or holy spring—was bestowed on it by Charlemagne from a spring of water which until 1837 was to be seen issuing from under the high altar of the church of St Kilian. In 1225 Heilbronn became a free imperial city. It was frequently besieged during the Thirty Years' War, and the ravages were with France. In 1808 it came into the possession of Württemberg.

HEILIGENSTADT, a town of Prussian Saxony, government district of Erfurt, is situated on the Leine and on the railway from Halle to Cassel, 33 miles E. N. E. of Cassel. It possesses an old castle, formerly belonging to the electors of Mainz, one Evangelical and two Catholic churches, a Catholic gymnasium, a Catholic normal school, two orphanages, and an infirmary. The principal manufactures are woollen wares, cigars, paper, bone dust, and needles. The population in 1875 was 6193.

Heiligenstadt is said to have been built by Drogobad, and was formerly the capital of the principality of Heilfeld. In 1022 it was acquired by the archbishop of Mainz, and in 1108 it came into the possession of Henry the Proud, but when Henry the Lion was placed under the ban of the empire it again came to Mainz. It was destroyed by fire in 1388, and was rebuilt in 1478 by Count Henry the Young of Schwarzburg, and in 1625 by Duke Henry of Brunswick. In 1803 it came into the possession of Prussia.

HEILSBERG, a town of Prussia, capital of a circle in the government district of Königsberg, is situated at the junction of the Surava and Alle, 38 miles S. of Königsberg. It has one Evangelical and two Catholic churches, and an old castle formerly the seat of the prince-bishops of Pomerania, but now used as an infirmary. The principal industries are cloth-weaving, yarn and thread spinning, dyeing, and brewing, and there is considerable trade in grain. The population of the town in 1875 was 5762.

The castle founded at Heilbrunn by the German knights in 1310 became afterwards the property of the counts of Hain. In 1308 made it their seat—in honour of which it retained for 560 years. On the 10th June 1807 a battle took place at Heilbrunn between the French and the Russians under Bismarck, which, although the French who attacked thought it prudent to withdraw before a victory declared for either side, resulted on the following day in the retreat of the Russians.

HEILSBRONN, or **KLOSTER-HEILSBRONN**, a market-village in the Bavarian government of Middle Franconia, with a station on the railway between Nuremberg and Ansbach. In 1871 it had only 998 inhabitants, but in the Middle Ages it was the seat of one of the great monasteries of Germany. This foundation, which belonged to the Cistercian order, owed its origin to Bishop Otto of Bamberg in 1132, and continued to exist till 1555. Its sepulchral monuments, many of which are signed by Hooker, *Heilsbronner Antiquariatschatz* (Ansbach, 1731-40), were of exceptionally high artistic interest, ten burials of Nuremberg (it was their hereditary burial-place), three electoral princes, five margraves of Brandenburg, and many other persons of note having been laid to rest within its walls. The buildings of the monastery have all disappeared, with the exception of the fine church, restored between 1851 and 1866. The "Monk of Heilsbronn" is the ordinary appellation of a didactic poem of the 14th century, whose *Seven Degrees*, *Daughters of Syon*, and *Life of Saint Alcuin* were published by Meisner at Berlin in 1870.

See "Notiz Heilsbronner" and "Annalen Heilsbronner" in *Pertz, Mon. Germ. Hist.*, vol. xvi., *Mittelalt. Deutsch. Gesch.* von Heilsbronn, Ansb., 1869. *Rehm, Ein Gang durch die und um die Mäuslein Knecht Kloster-Heilsbronn*, Ansb., 1876, and *Schilling, Kloster Heilsbronn, ein Denkmal an den Jahren der Forschung*, Berlin, 1877.

HEIM, FRANÇOIS JOSEPH (1787-1865), French painter, belongs to that group of painters in whose works we find the special characteristics of the Restoration. Born at Belfort on 16th December 1787, he early distinguished himself at the Ecole Centrale of Strasbourg, and in 1803 entered the studio of Vincent at Paris. In 1807 he obtained the first prize, and in 1813 his picture of The Return of Jacob (*Musée de Bordeaux*) won for him a gold medal of the first class, which he again obtained in 1817, when he exhibited, together with other works, a St John—bought by Vivant Denon. In 1819 the Resurrection of Lazarus (*Cathédral Autun*), the Martyrdom of St Cyr (St

Gervais), and two scenes from the life of Vespasian (ordered by the king) attracted attention. In 1833 the Re-erection of the Royal Tombs at St Denis, the Martyrdom of St Laurence (Notre Dame), and several full-length portraits increased the painter's popularity, and in 1831, when he exhibited his great canvas, the Massacre of the Jews (Louvre), Haum was rewarded by the legion of honour. In 1827 appeared the King giving away Prizes at the Salon of 1824 (Louvre—engraved by Jaxet)—the picture by which Haum is best known—and Saint Hyacinthe. Haum was now commissioned to decorate the Gallery Charles X. (Louvre), work for which he was thought eminently fit. Like many other painters of this period, Haum retained only enough of the high pitched ideal of David to make an awkward contrast with the lively colour and movement by which he tried to give interest to his subjects, and with the emptiness of form and expression which resulted from the hasty execution necessitated by the vast number of his commissions. Ridiculed by the romanticists, Haum maintained his position, and replaced Regnault at the Institute in 1834, shortly after which he commenced a series of drawings of the celebrities of his day, which are of much interest. His decorations of the Conference room of the Chamber of Deputies were completed in 1841, and in 1847 his works at the Salon—Champ de Mars and Reading in the Park at the Elysée Français—were again the subjects of attacks and great violence. Yet something like a taint of opinion in his favour took place at the exhibition of 1851, his powers as a draughtsman and the occasional merits of his composition were recognized, and toleration extended even to his colour. Haum was awarded the great gold medal, and in 1855—having sent to the Salon no less than sixteen portraits, amongst which may be cited those of Cuvier, Geoffroy de St Hilaire, and Madame Hersent—he was made officer of the legion of honour. In 1859 he again exhibited a curious collection of portraits, six-fifty members of the Institute arranged in groups of four, and six years later, on 29th September 1865, he died, at the age of seventy-eight. Besides the paintings already mentioned, there is to be seen in Notre Dame de Lorette (Paris) a work executed on the spot, and the museum of Strasburg contains an excellent example of his easel pictures, the subject of which is a Shepherd Drinking from a Spring.

IRBINE, HENRIOT (1799–1856), poet and journalist, was born, according to the most trustworthy accounts, on the 13th December 1799, at Dusseldorf, of Jewish parents. His father, after various vicissitudes in business, had finally settled at that town, and his mother, who seems to have possessed much energy of character, was the daughter of a physician of the same place. Haum received the rudiments of his education at the gymnasium or *lycée* (as it was called during the foreign occupation) of his native town, and, although not an especially apt or diligent pupil, he acquired while there a good knowledge of French and English,—he tells us that *Gulliver's Travels* in the original was one of the favourite books of his childhood,—as well as some measure of the classics and Hebrew. But if the influence upon him of his teachers and their teaching was unimportant, not so that of the public events amid which he grew up. His early years coincided with the most brilliant period of Napoleon's career, and the boundless veneration which he is never tired of expressing for the emperor throughout his writings shows that his true schoolmasters were rather the drummers and troopers of a victorious army than the Jesuit fathers of the *lycée*, while, if to the vivid personal impression produced upon him by the pomp and circumstance of the imperial garison in his birthplace there be added the public, and in a manner national, enthusiasm for Napoleon which he must

often have heard vented by his elder co-religionists—who hailed the conquest as a temporal Messiah!—the weighty bearing of his boyhood upon his subsequent fortunes becomes fully apparent. Upon his quitting school, attempts were made to engage him in commerce, but his father and uncle, the latter a wealthy banker of Hamburg, soon perceived that he was bent upon travelling a different path from that which they had followed. It speaks well for both these men that they should have refrained from coercion upon making this discovery, and Solomon Haum, the banker, at once gave his nephew an earnest of the generous treatment the latter was subsequently to experience at his hands, for he came forward with money to enable his young kinsman to go to a university, his sole stipulation being that his protégé should study with the view of entering the legal profession. Haum gladly accepted his uncle's terms, and entered the university of Bonn in the spring of 1819. During his stay there he was an eager student, but the subjects to which he devoted himself had no connexion with the profession which had been chosen for him. He seems to have attended no lectures save those on literature and history—notably A. W. von Schlegel's, and he not long afterwards acknowledged his obligations to Schlegel by dedicating a sonnet to him as a tribute which he called in later days by a wanton and outrageous attack upon the veteran critic in *Die Romantische Schule*. Why Haum left Bonn does not clearly appear, but it is at Göttingen that we find him in the autumn of 1820. His stay here was even shorter than at Bonn. In February 1821 the authorities of the "Georgia Augusta" rusticated him for some infraction of the duelling laws. Although from those beginnings Haum's academical career promised to pursue no very even course, he nevertheless determined, after his residence at Göttingen had been cut short, to seek a third university, and it was to Berlin that he now repaired, where Hegel was at the zenith of his renown. Whether or not the locum of this philosopher benefited him in any way—by giving him, for instance, as some have supposed, a certain dialectical precision of style—he has himself confessed that he seldom understood them, and in after years Hegel's ultra-conservatism and orthodoxy made him the constant butt of his former pupil's ridicule and sarcasm. But the interest of Haum's life in Berlin was social and not academic. He enjoyed the privilege of mixing in the best literary circles of the capital. He was a hearer of intimacy with Vanhagen von Ense and his wife, the celebrated Jewish Rachel, and at their house—the rendezvous of Germany's genius and learning—he frequently met such men as the Humboldts, Hegel himself, and Schleiermacher, while he lived on a still more familiar footing with a number of his own co-religionists, who, without having acquired European reputation, were men of varied and approved abilities. In an atmosphere of such geniality as this his gifts were rapidly displayed. He began ere long to contribute poems to the *Berliner Gesellschaft*, many of which were subsequently incorporated in the *Buch der Lieder*, and in 1822 a volume came from the press entitled *Gedichte von Heinrich Haum*, his first avowed act of authorship. He was still further employed at this time as the correspondent of a Rhenish newspaper, as well as in completing his tragedies *Almanzor* and *William Ratdoff*, which were published in 1823 with small success. He was now, indeed, fairly embarked upon his literary course. But he was still largely dependent upon his uncle, and in order so far to fulfil his engagements towards his benefactor, he returned to Göttingen in 1825, and shortly afterwards took his degree in law, having previously qualified himself for practice by publicly professing Christianity.

This act of "apostasy," as it has been called, calls for something more than a mere passing reference, for it not

only lud Heine open to contumely while alive, but has provoked adverse criticism of unusual severity since his death. That he was guilty of "apostasy" is no doubt verbally true, but there are two circumstances in this connexion which should always be remembered. The one is that Heine was wholly wanting in the religious sense—that he never was a Jew even nominally and by the accident of birth—so that he cannot, with any real propriety, be said to have forsaken the creed of his race, the other, that his family, by encouraging him to adopt a profession which could not be entered except by the gateway of "apostasy," tacitly left him free to take that step. In short, Heine's "apostasy" was a purely secular act, and, although there will doubtless be found many to stigmatize him all the more blackly for this very reason, candour appears rather to require that this change of faith, if such it can be called, should be classed as one of his most venial offences, being the plainly outward act of one who throughout life made himself peculiarly obnoxious to the imputation of malice and bad heartedness.

Heine seems never to have made any serious attempt to practise law. His life from the year 1826 until his death was devoted entirely to literature, and more especially to journalism, which alone indeed was the main source of his income for many years. At first he lived in Hamburg, and then it was that, besides the *Buch der Lieder*, the earliest portions of the *Reisebilder* appeared, both of which, but particularly the latter, at once created an immense sensation throughout Germany, not only among the youthful and enthusiastic, who found their own sentiments expressed by the new writer with the happiest audacity, but amongst such dignified and *respectable* personages as Metternich and Gentz. In 1827 Baron Cotta, the Bavarian publisher, offered Heine, who had risen at a bound into celebrity, the joint-editorship of the *Allgemeine Politische Annalen*. The young author accepted the offer, and betook himself to Munich in the winter of that year, after having paid a visit to London, where he found every person and everything detestable save Canning and his policy—and it may be said here in passing that a most violent hatred of England forms a marked feature of all Heine's writings. He remained for a considerable period in the South-German capital, and it was owing, not to any disagreement with his employer, but to the demands of the court of Prussia, which was not long of taking umbrage at his freedom of opinion, that his editorial function ceased so abruptly as it did. What the secret history of the next two or three years of his life was—whether from the very first he really was an object of especial disfavour at Berlin, or whether, as is quite as likely, taking his vanity and love of publicity into account, he exaggerated his powers of offence beyond the endurance of the Government there, and forced it into what seemed a petty persecution—he presently perceived that he must either quit Germany altogether or prepare for a life time perhaps of fortress-imprisonment. He did not long hesitate between the two alternatives, and on the 1st of May 1831 Heinrich Heine left his native land for Paris, where he lived for the rest of his life, only once recrossing the Rhine, in 1843.

Just as his adoption of Christianity has led to Heine's being pronounced "apostate," so has his self-expatriation caused German writers to denounce him as "renegade." But the one accusation is as groundless as the other. In the first place Heine was a Jew, in spite of his Christianisation, and cannot therefore rightly be called a "renegade" against Germany—least of all when the degraded social and political status of his race in that country at the date of his emigration is recollected. Then again his writings were systematically subjected to the cruellest mutilations, and it is tolerably certain that had he remained in the "Fatherland," he would sooner or later have been

deprived of all power of public speech. Was it any wonder, seeing that he had adopted the profession of letters, that he should have turned his back upon such a prospect? If at any rate was the best judge, and it will become Germany to call him "renegade," when, had he continued to tarry among them, their literature would probably have suffered an irreparable loss. At the same time, and for the same reasons, it is equally inept to assert that he was in the essential qualities of his mind a Frenchman who gravitated towards Paris by a sort of intellectual necessity. The necessity (to use that word) was physical. Heine would never have left Germany could he have freely expressed his opinions there.

After settling in his new home, where his life for many years must have been as gay and brilliant as latterly it was sad and somber, and where he speedily became more or less intimate with such writers as Balzac, Dumas, the elder, George Sand, Victor Hugo, and Thophile Gautier, Heine devoted himself more exclusively than ever to journalism, and from 1831 until 1847, he was an active and indefatigable publicist. The two series of papers entitled *Französischer Zustände* and *Zeitung* contain a selection from his press contributions during these years, and even at this date they well repay perusal, not only by the brilliancy of wit and elegance of style which they possess in common with almost all his writings, but also by the remarkable sagacity of their political *opinions*. Alongside of this main stream of journalism, he also kept up a subsidiary current of literature in its more proper sense—although it may be said that all his writings are of an occasional nature—and to this we owe the *Salon* (1833–39), which comprises among other pieces a series of articles, "Zur Geschichte der Religion und Philosophie in Deutschland," which had originally appeared in the *Revue des deux Mondes*, and in which Heine came forward as the introducer of German thought to the reading world of Paris. The *Salon* also contains several admirable papers in criticism, and a strange, fragmentary medley of sentiment and satire, in its author's most characteristic vein—"Die romantische Nacht." To this period, too, belongs *Die romantische Schule*, to which reference has already been made, and the substance of which is sufficiently indicated by its name. In 1839 *Shakespeare's Mädchen und Frauen* appeared—Heine acting in this slight work as eiccone through a gallery of Shakespeare's heroines. The year 1840 was signalized by the publication of *Heinrich Heine über Ludwig Burne*, a brochure of the witiest and most trenchant satire, in which the German refugees in Paris—a fraternity whom Heine always anxiously avoided—were far more severely handled than was the defunct agitator whose name it bore, and who, it may be noted, was himself a Jew. In 1844 *Deutschland, ein Wintermärchen*, came forth—the result of the visit to Germany which has been alluded to as the sole journey of the kind which Heine undertook, and this effusion may be ranked, along with a similar performance, *Atta Troll* (1846), as belonging to his most inferior writings. It was in 1848 that Heine, in the very hey-day of his activity, and with gigantic projects swelling within him for the foundation of a journal, was suddenly prostrated by the disease which finally carried him off, though not before it had confined him for seven years upon the "mattress grave" of mournful notoriety. His sufferings throughout that time are reported to have been frequently excruciating, and he at length grew so habituated to the use of opium that the very largest doses failed to afford him relief. But when his mindy—a softening of the spinal cord—allowed him to awake, his intellect was as clear and vigorous as ever, and it is to these closing years of his life, harrassed as they were, that we are indebted for the finest and most finished of all his poems—for the two collections, that is to say,

Romanzo (1851) and *Neueste Gedichte* (1853-54), as well as for the various pieces posthumously published in *Heine's Letzte Gedichte und Gedanken*. It was from his "master's-grave" too that the dying man put forth his *Gedächtnisse an Confessions*, the psychological interest of which is very great, whatever their claim to trustworthiness may be. Heine bore the misery of his protracted death-bed with forbearance, nay, with cheerfulness, assiduously attended by his wife Mathilde, and towards the end by that mysterious lady whom he called "Die Monche," and who was, it now appears, a Madame Kunitz, and there are many anecdotes on record of his bearing in the midst of his trials—and heavier trials seldom fell to the lot of man—which go far to prove that he possessed a healthy *joie de gaillard*, for which his writings are scarcely likely to gain him credit. He died on the 17th February 1856 in Paris, in the Rue d'Amsterdam, and lies buried in the cemetery of Mont maitre.

We have called Heine "poet and journalist," but his reputation has, naturally enough, now come to rest almost exclusively upon his poetry, and above all upon his songs—the *Buch der Lieder* having passed through upwards of twenty-five editions. This great popularity may no doubt (and especially in foreign countries) be attributable, to a certain extent, to the singular good fortune which has befallen to very many of these songs the music of such composers as Schumann and Mendelssohn. But still, when all definitions upon this point are made,—and the true view of the matter probably is that the poet and his composers are mutually obliged,—the fact remains that Heine is one of the great song writers of the world, not unworthy of a place beside Burns and Béranger, although far less masculine and passionate than the one, and far less jovial and debonair than the other. The intense individualism which prevented him from ever becoming a literary artist in any other department—his dramas and essays in fiction are worthless—stood him in excellent stead in the lyric field,—was a positive and essential strength indeed, for, after all, a song to appeal to men's hearts must be an utterance of personal experience. And this condition is amply fulfilled in the *Buch der Lieder*, the greater portion of which was the direct outcome of a sentiment entertained by the poet for one of his consorts—a sentiment, by the way, which has been alluded to by German writers as a mere *Cousinen-schwärmerei*, while others (not Germans) have affirmed that all Heine's bitterness and cynicism in after life arose from its having remained unrequited. On the whole, Heine as a song writer is a fit descendant of Walther von der Vogelweide and those old *Minnesänger* who of yore assembled in the halls of princes, and recounted their sorrows and their joys—of those nameless bards, too, who sang the *Völkchen*, and when all his other writings are forgotten, he will be remembered by such imperishable gems as "Die Rose, die Lili, die Taube, die Sonne," "Auf Flügeln des Gesanges," and "Du bist wie eine Blume." There is much, too, of great beauty in many of his ballads and narrative pieces, witness among others, "Spanische Aftiden," "Die Prinzessin Sabat," "Jehuda-ben Halevy," "Bosser Getraume"—a piece of the most exquisite pathos and simplicity—and "Die Insel Bimini." But too often, no matter how sweet a chord is struck at the beginning, a dissonance creeps in, to end in a crashing discord, and the outraged reader starts like one who should suddenly see Romeo and Juliet fall to grimoacing and squeaking like Punch and Judy. Heine's confession that poetry was no more than his "holy plaything" would have been entitled to our unqualified acceptance had he omitted the adjective.

But when we turn to his prose-writings—to his "journalism," that is to say, for, as we have remarked, almost all his prose falls under this category, in its widest acceptation

—we see the man Heine indeed, not perhaps, as he was ambitious of being regarded by posterity, in the full panoply of a "soldier of human emancipation," but at any rate as no contemptible assailant of obscurantism and philistinism. Beside such a redoubtable champion of the catholic reason of mankind as Lessing "of theoponicus battle axe," he looks somewhat small, it is true, and his rapier somewhat gimcrack. But ridicule will often reach whither heavier weapons cannot, and pierce the elephantine hide of philistinism and dulness, after these have been attacked in vain by battering-rams, and Heine was a master of it. The worst is that in unscrupulous hands—and no one was more unscrupulous than he—it may be turned to illegitimate use, and come to be indulged in finally for its own sake. How easily Heine became the slave of his propensity in this direction may be seen in the two works—which come his best and most characteristic writings, notwithstanding—*Zur Geschichte des Religion und Philosophie in Deutschland* and *Die Romantische Schule*. Both these abound in the most irrelevant passages, especially the former, wherein such philosophies as Kant, Fichte, and Schelling—clearly serve a higher purpose than to be used as pegs whereon the writer may hang his jests. And admirable these are. Nothing can be better, for instance, than his account of how Kant (who is parenthetically described as a man whom Nature intended to sell coffee and sugar across a counter) came to postulate a Deity in his practical, after having exploded that idea in his theoretical system. He did this, says Heine (most adroitly hitting one of the chief *oppos*), for the sake of his old man-servant Lampo, who looked so dimly at the conclusions of the Pure Reason that the philosopher was moved to compassion! *Die Romantische Schule*, being concerned for the most part with its author's contemporaries, is far more violent than the treatise just mentioned, but equally happy, and it aimed a death blow at a school which rivalled the wildest and most licentious ravings of a Monk Lewis and the most settled horrors of an Ann Radcliffe. And here it may be said, in connexion with the attack upon Schlegel occurring in this essay, that Heine's onslaughts were always open and above-board, unmerciful and sometimes grossly brutal as they were. He was a literary swashbuckler, it may be (though that term is singularly inapplicable to one who wrote in such a style), but he was neither a literary assassin nor a literary ghoul. Even his attack upon Büchner was really aimed, as we have said, at men who were alive to resent it, and it was resented, though from a strange quarter. Büchner's widow's husband challenged Heine, and the latter was slightly wounded in the encounter.

Of the *Reisebilder*, Heine's most voluminous and best-known prose work, and that which originally gave him fame, small space remains to speak. But if we except its first and third books, it has been greatly overrated. It is easy to understand the popularity it acquired upon its first appearance, falling as it did like a breath of genuine life upon a land well-nigh asphyxiated by high art and the "Hubsch Objectiv."—but nowadays, notwithstanding its undoubted mirth-provoking qualities, it chiefly serves to point out the gulf which was fixed between its author and him who took the *Sentimental Journey*. The most that can be said for it is that some might have written it had he been a German Jew.

The best edition of Heine's works is that published by Hoffmann and Campe, *Heine's Sämmtliche Werke*, 20 vols., Hamburg, 1866. Another edition has appeared in America, *Heine's Sämmtliche Werke*, in 7 vols., *Heine's Lieder und Leben*, by Adolph Strodtmann, Berlin, 1870, is the only life of Heine entitled to consideration, although the pleasure of reading it is certainly marred by its length. A biography of the poet has also appeared in England, *Life and Opinions of Heinrich Heine*, by W. Stigand,

1876. Mr. Matthew Arnold has, in his *Essays in Criticism*, handled Hamlet with his accustomed grace and fluency. Mention may also be made of *1744, Writings, and Poems of Heinrich Heine*, by J. Snodgrass, London, 1870, a collection of extracts from Heine's works in an English dress; a translation, *Heine's Poems, Complete*, by Edgar A. Berington, C. B. was issued in Bohn's Standard Library. His poems have not as yet received adequate renderings, although a version of the *Waldmühle* has been put forth in America.

HEINECCIUS, JOHANN GOTTFRIED (1681-1741), a celebrated jurist, was born 11th September 1681 at Eisenberg. He studied theology at Leipzig and law at Halle, and at the latter place he was appointed in 1713 professor of philosophy, in 1718 extraordinary, and in 1720 ordinary professor of jurisprudence. He subsequently filled legal chairs at Franeker in Holland and at Frankfurt, but finally returned to Halle in 1733 as professor of philosophy and jurisprudence. He died there, 31st August 1741.

Heineccius belonged to the school of philosophical jurists. He endeavoured to treat law as a rational science, and not merely as an empirical art whose rules had no deeper, sooner than expediency. Thus he continually refers to first principles, and he develops his legal doctrines as a system of philosophy. His chief works are one *Adquisitiones Romanæ seu Jurisprudentiæ Aristotelicæ Sæptæ Leges* (1718), *Methodus Juris Civilis Romanæ seu Germanicæ* (1733), *Elementa Juris Germanici* (1735), *Elementa Juris Naturæ seu Gentium* (1737), *Elementa Juris Naturalis*, London, 3 vols. (1738). Besides these works he wrote on purely philosophical subjects, and edited the works of several of the classical jurists. His *Opera Omnia* (9 vols., Götting, 1771 &c.) were edited by his son Johann Christian Gottlieb Heineccius.

HEINECKEN, CHRISTIAN HEINRICH (1721-1728), a child remarkable for extraordinary precocity of intellect, was born on February 6, 1721, at Lubek, where his father was a printer. Able to speak at the age of ten months, by the time he was one year old he knew by heart the principal incidents in the Pentateuch. At two years of age he had mastered all the sacred history, at three he was intimately acquainted with history and geography, ancient and modern, sacred and profane, besides being able to speak French and Latin, and in his fourth year he devoted himself to the study of religion and church history. This wonderful precocity was no mere feat of memory, for the youthful savant could reason on and discuss the knowledge he had acquired. Crowds of people flocked to Lubek to see the wonderful child, and in 1724 he was taken to Copenhagen at the desire of the king of Denmark. On his return to Lubek he began to learn writing, but his sickly constitution gave way, and he died, June 22, 1725.

The *Life, Death, Travels, and Death of the Child of Lubek* were published in the following year by his father Schuch. See also *Heinecken's Bibliothek*, vol. viii., and *Memories de Diderot*, Jan. 1781.

HEINSE, JOHANN JACOB WILHELM (c. 1746-1803), German romance writer, was born at Langenwieschen in the Thuringian Forest, February 16, 1746, or, according to some accounts, February 15, 1749. He was educated at the gymnasium of Schleimungen, and afterwards, through many privations, studied law at Jena and Erfurt. At Erfurt he became known to Wieland, and through Wieland's recommendation to the poet Gleim, who, attracted by some of Heine's early literary attempts, offered him assistance and a home, but at this time he made the acquaintance of an adventurer, Captain von der Goltz, and was induced to accompany him on his travels. Von der Goltz easily succeeded in corrupting the taste and misdirecting the talents of the young author, and the baneful influence of this friendship pervades Heine's writings. After parting with Von der Goltz Heine returned for a time to Langenwieschen, and afterwards, with Gleim's assistance, under the assumed name of Rost, a tutorship in the family of Von Massow at Quadenburg, which, however, he did not keep very long. In 1774 he went to Düsseldorf to assist J. G. Jacobi in the production of the *Jura* journal. In 1780 he obtained from Jacobi leave and the necessary funds

to travel in Italy. There he remained three years, living chiefly at Rome, where he was intimate with the painter Müller. In 1789 he obtained the post of reader to the elector of Mainz, who afterwards made him councillor and librarian. He died at Aschaffenburg, June 22, 1803.

Heine's works are—*Singschule*, H. Abt, 1771, *Dieben haben das Einkopf* translated from the *Stations* of Platonius, 2 vols., Schwabach, 1773, *Der Kuchler*, after Donat's *Croquis*, London, ed. by *Die Mannischen Geheimnisse*, Langen, 1784, two translations of Tasso's *Jerusalem Delivered*, 4 vols., 1781, and *Augusto's Orlando*, 4 vols., 1784, *Ardenhollo und die glückseligen Jüden*, 2 vols., Langen, 1787, *Heinrichs von Heubach*, 4 vols., Berlin, 1793, *Anweisung und das Schicksal*, 2 vols., in 1804, 1803. A collection of his entire works was published at Leipzig in 1838 in 10 vols., and another edition in 1867 in 5 vols.

HEINSIUS, or HAINZ, DANIEL (1580-1635), one of the most famous scholars of the Dutch Renaissance, was born at Ghent, June 2, 1580. The troubles of the Spanish war drove his parents to settle first at Vene in Zealand, then in England, next at Ryswyk, and lastly at Flushing. In 1594, being already remarkable for his attainments, he was sent to the university of Franeker to perfect himself in Greek under Henricus Schotanus. He stayed at Franeker half a year, and then settled at Leyden for the remaining thirty years of his life. There he studied under Josephus Scaliger, and there he found Mamix de St. Aldegonde, Janus Douza, Paulus Merula, and others, and was soon taken into the society of these celebrated men as their equal. His proficiency in the classic languages won the praise of all the best scholars of Europe, and offers were made to him, but in vain, to accept honourable positions at Leyden and elsewhere. He soon rose in dignity at the university of Leyden. In 1602 he was made professor of Latin, in 1605 professor of Greek, and at the death of Merula in 1607 he succeeded that illustrious scholar as librarian to the university. The remainder of his life is recorded in a list of his productions. He died at the Hague, February 25, 1635. The Dutch poetry of Heinsius is of the school of Roemer Vischer, but attains no very high excellence. It was, however, greatly admired by Martin Opitz, who was the pupil of Heinsius, and who, in translating the poetry of the latter, introduced the German public to the use of the rhyming alexandrine.

He published his engraved Latin poems in three volumes—*Verba* (1602), *Ætæa* (1603), and *Pœnæ* (1605), his *Emblematum Amatoria*, poems in Dutch and Latin, were first printed in 1601. In the same year he edited Theophrastus, Boetius, and Moschus, having edited Heinsius in 1603. In 1609 he printed his *Latin Orations*. In 1610 he edited Heinsius, and in 1611 *Amstelredamum*. In 1613 appeared in Dutch his tragedy of *The Manner of the Jews*, and in 1614 his *Tragedie De politice republice*. In 1618 he collected his original Dutch poems into a volume, *Heinsius*. He died at Tames in 1618, Levy in 1620, published his *Orationes De contemptu mortis* in 1621, and brought out the *Epistole* of Josephus Scaliger in 1627.

HEINSIUS, NIKOLAAS (1620-1681), Dutch scholar, was the son of Daniel Heinsius, and scarcely less illustrious than his father. While, however, Daniel was the type of the stationary scholar, Nikolaas was by temperament restless and impatient. He was born at Leyden, July 20, 1620, and early displayed an extraordinary precocity. His boyish Latin poem of *Beda Erpynata* was printed in 1637, and attracted much attention. In 1642 he began his wanderings with a visit to England in search of MSS. of the classics, it is unhappily recorded that he met with great discourtesy from the English scholars. In 1644 he was sent to Spa to drink the waters, his health restored, he set out once more in search of codices, passing through Louvain, Brussels, Mechlin, Antwerp, and so back to Leyden, everywhere collating MSS. and taking philological and textual notes. Almost immediately he set out again, and arriving in Paris was welcomed with open arms by the French savants. After investigating all the classical texts he could lay hands on, he proceeded southwards, and visited on the same quest Lyons, Marseilles, Pisa, Florence (where

he paused to issue a new edition of Ovid), and Rome next year, 1647, found him in Naples, from which he fled during the reign of Masaniello; he pursued his labours in Leghorn, Bologna, Venice, and Padua, at which latter city he published in 1648 his volume of original Latin verse entitled *Italia*. He proceeded to Milan, and worked for a considerable time in the Ambrosian library, he was preparing to explore Switzerland in the same patient manner, when the news of his father's illness recalled him hurriedly to Leyden. He was soon called away to Stockholm at the invitation of Queen Christina, at whose court he waged war with Salmasius, who accused him of having supplanted Milton with facts from the life of that great but unfortunate scholar. Heimsius paid a flying visit to Leyden in 1650, but immediately returned to Stockholm. In 1651 he once more visited Italy, the remainder of his life was divided between Upsala and Holland. He collected his Latin poems into a volume in 1653. His latest labours were the editing of Volturnus Paternus in 1678, and of Valerius Flaccus in 1680. He died at the Hague, October 7, 1681. Nicolaus Heimsius was one of the purest and most elegant of modern Latinists, and if his scholarship was not quite so perfect as that of his father, he displayed higher gifts as an original writer.

HEINSIUS, NIKOLAËS, an illegitimate son of the subject of last article, was born in 1655 at the Hague. At the age of twenty he wrote *De Delightful Idleness and Wonderful Life of Mycander*, a work of extraordinary humour and genius, the sole original romance produced in Holland during the 17th century. Dr. Ten Brink has pointed out that *Mycander* preceded *Guê Blaz*, which it curiously resembles, by at least forty years. The author, however, added nothing else to literature. He was disowned by his father, driven from the house, and in 1677 had to flee the country on account of a murder which he committed at night in the streets of the Hague. He lived a precarious life as an outlaw in Paris, Rome, and elsewhere, and died in obscurity.

HEIR. See INHERITANCE.

HELDER, or THIE HELDER, a township of the Netherlands at the northern extremity of the province of North Holland, directly opposite the island of Texel. Since 1810 it has been the terminus of the North Holland Canal, and it is now connected (since 1805) by railway with Alkmaar and Havlem. Its fortifications and its dykes are both constructed on an extensive scale, the former comprising four batteries and five forts, and the latter being the most striking on the whole coast. A garrison of 7000 to 8000 men is necessary for the defence of the place, and 30,000 men could be accommodated within the lines. The harbour, called the Nieuwe Diep, is one of the best in Europe. Its area is 6560 feet long by 330 to 490 broad, and it has depth enough for the largest vessels, which are admitted to the North Holland Canal by the Koopvaarders sluice. The Government arsenal comprises an extensive wet dock, a dry dock, an auxiliary establishments. Besides eight churches and a synagogue Helder possesses a palace for the board of marine, a royal institute for the education of naval cadets, a marine hospital, an orphan asylum, a town-house erected in 1836, and a meteorological observatory. The industries of the place are those usual in a flourishing seaport. Previous to 1819 the population was not much more than 2000, but since then it has rapidly increased. In 1870 the suburbs of Willemsoord, Nieuwe Diep, Nieuwstadt, and the Canal Head being included, the total amounted to 19,205. As a commune it numbered 18,366 in 1870 and 20,104 in 1874.

Helden was originally an offshoot of the now decayed town of Huisduinen. The first church was built in 1624, and though the harbour became a favourite resort of the whale fishers, it was not

till the construction of the Nieuwe Diep between 1770 and 1780, and its enlargement in 1781, that it attained its present importance. The place was secured. Under the Batavian republic the fortifications were extended and strengthened, and Napoleon still further improved them. In 1799 the English, under Abercromby, invited by the Batavians, threw out the Dutch and secured the capitulation of the Dutch fleet in the Zuyder Zee.

HELENA, daughter of Zeus and of Leda the wife of Tyndareus king of Sparta, was sister of Castor, Pollux, and Clytemnestra, and was married to Menelaus. According to Homer she was obliged by Aphrodite to flee with Paris to Troy, and after the Trojan War she returned with Menelaus and lived with him as queen in Sparta. She had only one child, a daughter named Hermione, who was married to Neoptolemus. In the Homeric poems her character is drawn with marvellous skill, forced by the gods to do what she repents, she seems to be separated from the wrong that she does, and remains always an object of interest and respect. Goethe (*Faust*, part i.) introduces Helena apparently to symbolize the Greek spirit acting on the modern mind. Among later poets the tales of Helen are much more complicated. She was carried off by Theseus to Attica in her childhood, but was recovered by her brothers. Her character often suffers much in the tales followed by lyric and tragic poets. Stesichorus and Euripides (*Helena*), however, relate that Paris on his homeward voyage was driven by stress of wind to Egypt. Ptolemy, king of Egypt, learning the facts, detained the Trojan Helen in Egypt, while a shadowy Helen was taken to Troy and fought by Menelaus on his way home from Troy. He was also driven to Egypt, and there found his true wife. After the death of Paris she is also said to have been married to his brother Deiphobus.

If we turn to the religious ceremonies and the genuine popular tales, we find traces of a more archaic Helen. As Helenus in Attica she was connected with the worship of Nemesis, whose daughter she is considered to be. In the Homeric poems and motifs of Iphigeneia, and we are said to have founded a temple of Iphigeneia, the goddess of birth. At Sparta she was honoured as presiding over the care of children, and was in fact so celebrated in her honour by the maidens. A tree apple is here connected with her worship there (see *Phœnx*, xxvii.), and in Rhodes she was worshipped by maidens with the epithet *Παιδοποιός*, a title of the very oldest kind of worship, where a sacred tree was worshipped as the embodiment of the god. In most of these cults connection with a moon goddess, the most important of whose functions was the care over child birth, is apparent, and we are led to regard *Εἰλενα* as an epithet of the moon, which legend is usually best secured from it and traced to an independent existence. For the account given of Gorgophone under *Goïones*. Beauty is a specially common attribute of the moon and of moon goddesses, such as Hecate. This makes it most probable that the word, like *Εἰλενα*, is connected with the root *eil*, to shine. The tale connecting Helenus with Achilles, who is clearly a sun god originally, which is known already to the writers of the *Cyprian*, are also very instructive. Over the Helian coast Achilles and Helenus were worshipped as united in the Mysian lands. With these we must compare the story of Cadmus and Harmonia (see *HERMONTIS*), and of Hades and Persephone, and we must remember that the two brothers of Helenus were closely connected with Attica. We may then look on it as probable that the tale of Helenus by Theseus is merely a device of homonymizing skill to connect the Helian of Spartan religion with the Helian worshipped in Attica. It is hardly a similar reason, but is continued to the tale which has itself found the undoubtedly historic fact of the destruction of Troy by a Greek tube or army. The worship of Aphrodite, the goddess whose influence in the story of Paris and Helen is so great, was common to Troy and Cythra. Many facts also point to a close connexion between Aphrodite and Helios. The Swan from whose egg she is born is the bird of Aphrodite. By the author of the *Cyprian* and in Attic tradition Helen is made the daughter of Nemesis, but Nemesis as a goddess of fate is clearly a deity and deity (see *Kuhn*, *ZfV*, i. 418), and therefore may be identified in origin with Aphrodite. We have here another instance of the intimate relation of the moon and dawn goddesses, and the possibility of dividing them by an old line (see *FRANZ*, III.). It would be at once a most instructive and a most interesting task

¹ Most appreciative and sympathetic analyses may be found in Gladstone's *Homeric Studies* and Mure's *History of Greek Literature*.

to trace the steps by which the antique pan-Greek goddess was gradually transformed into the charming heroine whom the notion of the *Iliad* reviveth. The data for reconstructing the history of this figure are more than usually full, and are so clear that a student of the most opposite schools (as Vahlen, Gutsch, Mommsen, Mühl, Böhler) have recognised in Helena the ancient goddess.

HELENA, SAINT, a woman of humble origin, said to have been the daughter of an innkeeper, was the wife of Constantine Chlorus. Of her nationality nothing certain is known. She had one son, Constantine the Great. In 302 A.D. Chlorus was raised to the purple by the emperors Diocletian and Maximian, and forced to divorce Helena to make room for a more noble wife. After her son became emperor she was treated with great respect and styled Augusta, and cities in Bulgaria and Lycaonia were after her named Helenopolis. She became a Christian when her son was converted, and during a pilgrimage to Jerusalem she discovered the Holy Sepulchre and the true cross. Her zealous patronage of their religion made her a favourite with the Christian writers, and finally procured her the honour of canonization, but pagan historians, such as Zosimus, regard her with dislike, and even question, though without ground, the legality of her marriage. Many coins occur with the name of Helena, but it is difficult or impossible in many cases to determine whether they belong to Saint Helena or to others of the family of Constantine bearing the same name.

HELENSBURGH, a town and favourite watering-place of Dumfriesshire, Scotland, is situated at the mouth of the Gatehead, a branch of the Firth of Clyde, opposite Greenock which is about 4 miles distant. It is 21 miles N.W. of Glasgow by railway. In 1776 the site of the town was advertised for leasing, and in 1803 Helensburgh, named after Lady Helen, wife of Sir James Colquhoun, the proprietor of the soil, was created into a burgh of barony, under a prior and council. The boundaries have since been enlarged. The town is pleasantly situated on a gentle slope, the streets mostly intersecting each other at right angles, while many of the houses are surrounded by gardens,—peculiarities that produce an agreeable regularity and openness. A handsomeburgh hall was erected in 1879. Near the town is a hospital, and within its boundaries a public park. Convenient as headquarters for visiting the whole district of the Clyde, and connected with Glasgow by both rail and steamer, Helensburgh is much frequented in summer. The population in 1871 was 6231, it is now (1880) estimated at fully 10,000.

HELILAND (i.e. *Helaland*) is an Old Saxon poem of the 9th century. According to some critics it is a fragment of a larger work which dealt with the entire historical material of the Old and New Testaments. The poet which we now possess sets forth the life of Christ as told by the four evangelists, whose various narratives the author seeks to harmonize. The poem is said to have been composed by a Saxon writer at the request of the emperor Louis the Pious, but who the author was, except that he was a Saxon, we have no means of knowing. The general opinion is that he lived in Westphalia, but even this is uncertain. Like all the most ancient remains of Teutonic poetry, *Heliland* is written in alliterative verse, of which the writer had a perfect mastery. It is almost the only remnant of the Old Saxon dialect, and has therefore a high philological value, but it is still more interesting from a literary point of view. The poet does not merely repeat his authorities, while true to the main facts of the original story, he allows his imagination to play upon them in a free and poetic spirit. It is realized with intense force the incidents in the career of the Founder of Christianity, and gives vitality and definiteness to the received conception of His character. The diction is simple and popular, but marked by an elevation of sentiment adapted to the theme and to its epic treatment, and by a happy phrase the author often succeeds in

imparting to his style colour, variety, and animation. The 9th century is remarkable in the history of Old English and of Old Norse poetry, the *Heliland* affords proof that the impulse which revealed itself in these two literatures was also experienced to the full by the higher minds of Germany. The historical aspects of this great work are hardly less important than those which claim the attention of the purely literary student. Of all the German tribes the Saxons were the last to submit to the influence of Christianity. They regarded baptism as the symbol of Frankish supremacy, and clung as long as they could to the ancient Teutonic faith. Not until Charlemagne, after more than thirty years of warfare, forced upon them the Frankish institutions did they generally accept the new creed, and even then, while they talked of Christ and the saints, they thought of Wodan and Thor, and took delight in the heathen poetry which had been handed down from remote periods. Louis the Pious was of a gentle and conciliatory nature, and by treating the Saxons with kindness obliterated to a large extent the recollection of his father's severity. *Heliland* was one of the works with which he and the clergy endeavoured to replace pagan literature, so that we may regard it as the monument of a struggle between two civilizations. The author is dominated by the ideal, and the sympathies of the Catholic Church, but on occasional topics he reminds us of the order of life that was passing away, and these have been found suggestive by writers on German ethnology.

Heliland received its name from A. Schmeller, who edited it (Munich, 1830-40) from the two existing manuscripts, one of which is in the Dittichheim, the other in Munich (formerly in Bamberg). More recent editions have been issued in Bonn (Blunck, 1866), accompanied by a modern edition, Hilde (ed. of Paderborn, 1878), and Buckert (10th volume of *Deutsche Dichtungen des Mittelalters*, Leipzig, 1878). These editions are modern in German by Kennen (Berlin, 1877), Giese (Hamburg, 1874), the revised edition, Cassel, 1879), Rapp (Stuttgart, 1878), and Buckert (ed. of Leipzig, 1880). See also *Heland, Deutsche Heland*, in *Heland* (ed. of Hamburg, 1882), Winkler, *Der Heland und seine Quellen* (Leipzig, 1883), Giese, *Die Quellen des Heland* (Gießen, 1880), and *Heland und die anglosächsische Gattung* (Halle, 1875).

HELICON, a mountain, of more strictly a mountain range, of Boeotia in ancient Greece, celebrated in classical literature as the favourite haunt of the muses, is situated between Lake Copais and the Gulf of Corinth. On the fertile eastern slopes stood a temple and grove sacred to the Muses, and adorned with beautiful statues, which, taken by Constantine the Great to beautify his new city, were consumed there by a fire in 404 A.D. It is said by Pliny the famous fountains of poetic inspiration, Aganippe and Hippocrene, the latter fabled to have gushed from the earth at the tread of the winged horse Pegasus, whose favourite browsing place was there. At the neighbouring Asien dwelt the ancient Hesiod, a fact which probably enhanced the poetic fame of the region. Pausanias, who describes Helicon in his ninth book, asserts that it was the most fertile mountain in Greece, and that neither poisonous plant nor serpent was to be found on it, while many of its hills possessed a marvellous healing virtue. The highest summit, the present Paleovuni (old hill), rises to the height of about 5000 feet. Modern travellers, aided by ancient remains and inscriptions, and guided by the local descriptions of Pausanias, have succeeded in identifying many of the ancient classical spots. For details of modern research see Clarke's *Travels in Various Countries* (vol. vi, 1818), Dodwell's *Classical and Topographical Tour through Greece* (1818), and Leake's *Travels in Northern Greece* (vol. i, 1835).

HELLIGOLAND (German, *Heligoland*), *Heligeland*, or *Helig Land*, as the natives call it, is one of the Friesian Islands, and an English possession, situated in the North

Sea, 54° 11' 31" N lat., 7° 51' E long., 36 miles from Cuxhaven at the mouth of the Elbe, and about 100 from Hamburg. Though the red cliffs of the Rock Island are not familiar to the voyager entering the Elbe, there are in reality two islets, the second being the Düne or Sand Island, now lying a quarter of a mile east of the main one, the light at one time connected with it by *de wad*, a neck of land which the sea broke through and destroyed in 1720. The Rock Island is nearly triangular in shape, surrounded on every side by steep cliffs, the only beach being the sandy spit where the landing place is situated, near the south-east point. On this islet there are some 500 houses, divided into a lower town on *Ute land*, on the spit, and an upper town or *Oberland*, situated on the cliff above and connected with the lower town by a wooden stair of 190 steps, the only possible mode of communication between the two sections. The portion of the flat topped rock not occupied by the houses, the church with graveyard, the Government installation, and place for a battery, comprises a little pasture-land, a few cabbage gardens, potato patches, and a powder magazine at the north end of the rock. About 200 sheep, tethered to patches of spots, feed on the scanty herbage, eked out by potato-peelings and halms, cabbage blades, or any other vegetable refuse, which is carried out to them every morning. From one end of the island to the other runs a footpath, called by the Heligolandians the "Lund-weg" or High Road, but better known to visitors by the name of "Kastoffel-Allee" (Potato Walk). There is also a lighthouse, but, though a few guns are placed behind a rude earthwork, there are no fortifications except the inaccessible cliffs of the island, and no garrison of any kind unless a few coast guardsmen be considered as such. The greatest length of the island, which slopes somewhat from west to east, is 5880 feet, and the greatest breadth 1815 feet, its circumference 13,500 feet, its average height 105 feet, and the highest point 216 feet. The Düne or Sand Island is little more than a sand-bank covered with scanty herbage, and imperfectly bound together by bent grass and low crevices. It is only about 200 feet above the sea at its highest point, but the drifting sands and the constant mounds of the sea make the height rather variable. The sea-bathing establishment is situated here, but, with the exception of the restaurant keeper and waiters, and the attendants who drag the bathing coaches into the sea, there are no residents. A shoving beach of white sand presents excellent facilities for bathing, everything is under strict Government surveillance, the boats in which the bathers cross in the morning, the house of bathing, and the tariff being all regulated by law. Approached from the sea the Rock Island, with its red-lit houses perched in a little cluster on the red cliff—"Am Falm," as it is called—looks very picturesque, and even the narrow black-paved or sandy lanes of the town are not deficient in a certain degree of quaintness. There are—with the exception of a wheelbarrow and an occasional pedambulator—no wheeled carriages in the island, and no horse or other beasts of burden. Even the two cows kept in the Unterland for the use of invalid visitors, and whose milk is sold at the apothecary's shop, are removed at the end of the bathing season to Cuxhaven, the island not supplying food for both man and beast. Mud is unknown on the streets, the rain only serving to wash their sloping surfaces clean as the scoured floor of the housewife's kitchen. Most of the houses are built—this lower half at least—of brick, but some are of wood. There are a theatre, a "conversation house," and a number of hotels and restaurants, though during the season nearly every house is more or less let out to "badegoster"—visitors for sea-bathing forming the great source of the islanders' prosperity. In both the lower and the upper

town there are numbers of shops, but the articles for sale seem to be chiefly intended for the summer "bathing guests," the natives getting most of their supplies from Hamburg or Bremen. The dwellings of the fisher-folk are reasonably clean, and the interiors bear evidence of the seafaring character of the population. Some of the houses have little gardens with flowers, cucumbers, &c., in front of them; and in places protected from the sea breezes there are a few fruit trees. At the foot of "the stair" are one or two lime trees sheltered by the contiguous houses, they are looked upon by the Heligolandians as objects of national pride.

During the summer from 2000 to 3000 people visit the island for sea bathing. Most of these are from Hamburg, English, or other "guests" being rare. There are no English residents, the officials, the governor excepted, being either natives or Germans, and German, when Frisian is not employed, is the official language, though for form's sake on the postage stamps English and German words appear in duplicate. The natives speak a dialect of Frisian, barely intelligible to the other islands of the group. They are perfectly content with the almost perfect autonomy they enjoy under the English Government. There is little emigration, and accordingly the population is slowly increasing. In 1879 the number was a little over 2000. There is regular communication with Bremen and Hamburg in the summer and autumn months, but during the winter the island is almost deserted for weeks at a time, owing to the weather, drift ice, and other causes. It is said that insanity and suicide are in consequence not rare. Epidemic diseases occur, though they do not commonly spread, but scurvy, owing to the poor character of the islanders' food, attacks three-fourths of the population. In ten years there were 309 deaths—about 15 to the 1000, while during the same period—from 1863 to 1872 inclusive—there were no less than 17 suicides. At one time the population did not exceed 300, and it was only when it increased to over 1000 that the inhabitants had to dispense with the few houses they kept to till their patches of land. This is now done with the spade, and loads are conveyed either in wheelbarrows or in shallow willow baskets.

The temperature of the Oberland is, owing to its exposure, about 1° lower than that of the Unterland. The following are the means of the month, from a series of observations taken for seven consecutive years at the lighthouse built on the highest point of the island—January, 51° Fahr.; February, 53°; March, 57°; April, 63°; May, 69°; June, 76°; July, 82°; August, 81°; September, 86°; October, 88°; November, 40°; December, 84°—the mean temperature of the whole year being 47° Fahr. The winter season is somewhat very stormy, and very much the same may be said of the summer, the rain leaves a delicate deposit of salt after it has crystallized. May and the early part of June are very wet and foggy, so that the first visitors do not arrive until the middle of the latter month. The rocks composing the island are of Tertiary age, but the sandstone, lias, iris, corals, muschelkalk, and chalk (now denuded), topped by Phocæne—"the brown rock," in which are found the scales and teeth mostly of fossilized fishes, including *Mollusca*, and the bones and leaves of *Gymnosperms*, a *Quercus*, an *Astruc*, a maple, a plant allied to a hoya (*Stenopterygiopsis heligolandica*), &c. The cliffs are worn into caves, and around the Rock Island are many fantastic arches and columns of rock. There is no just ground, however, for believing that the Rock Island was ever higher than it is,—the tales of the great size of Heligoland—its numerous churches and villages in early times—being doubtless exaggerated by tradition, while the maps affecting to show its former extension doubtless relate to the Sand Island, which was undoubtedly much larger in very recent periods, and is now yearly becoming smaller. The natural history presents nothing remarkable. There are no cliffs or light on it during their migration, all belong to the mainland or to the North Sea. Haller has enumerated 220 flowering

¹ Summerring, Die südlichen Zustände Heligolands, mit besonderer Berücksichtigung der Osmogasterien des Luft, 1873, pp. 14, 13.

² Götke, *Edinburgh New Philosophical Journal*, n. s., ix., p. 288; Hensen, "Naturwissenschaften," p. 808 (Jura, 1865, p. 55), Coudere, *1873*, p. 1873.—Mr Götke, the island secretary, is preparing a special work on Heligoland ornithology.

In favourable localities, however, heliography possesses important advantages for military signalling over other methods, the principal being the portability of the apparatus, the great distance to which messages can be sent without retransmission, and the fact that the signals are visible to those only who are on the direct line of signalling.

The signals are produced by causing the reflected beam to appear and disappear or be obscured alternately at the distant point, the intervals of appearance and obscuration being usually varied in length, so as to produce the combinations of long and short signals known as the Morse alphabet. This is done in two distinct ways. In the first of these, known as signalling by "appearance," the reflected beam or "flash" is obscured from the receiving station except when a message is being transmitted, the flashes then giving the signals or "dots" and "dashes"; while in the second method, or signalling by "obscuration," the flash is kept continually on the receiving station, and only obscured for intervals forming signals. The first method is more easily read by learners; the second is less fatiguing to the eye, and possesses the advantage of enabling the signaller to correct the adjustment of his instrument at any time.

Glass mirrors with a plane surface are employed, hence the angle of divergence of the extreme rays in the reflected beam is the same as that subtended by the sun's diameter at the point, or about 33 minutes of arc; this small divergence rendering the flash visible to great distances.

The distance through which signalling by this method can be carried on depends on the size of the mirror employed and the angle of reflexion of the rays, a large mirror giving a more intense "flash" than a small one, since it reflects more rays, and being therefore visible to a greater distance; also when the angle of reflexion is nearly a right angle the flash will be more intense than when the rays are only diverted through a small angle from the greater extent of surface exposed to the sun's rays. The range, however, depends to so great a degree on the state of the atmosphere that it is impossible to assign any limits to the distance that the flash might be seen through in exceptionally clear weather. From the Himalayas a 5-inch mirror has been found to give very distinct signals over a distance of 60 miles; but when the air was at all misty a very much larger mirror had to be employed.

The more perfect reflexion when the angle between the direct and reflected rays is large is not sufficient to compensate for the loss of intensity caused by the small number of reflected rays. Hence when this angle is greater than a right angle two mirrors are used, the sun's rays being reflected from one back to the other and thence to the distant point. This is called the duplex method of working.

Two forms of instrument are at present used in the British army. In the one known as Babbage's field heliostat the mirrors are square, the sun mirror having a side of 5 inches, and the signalling mirror 4 inches. The object of this difference is to ensure the latter receiving the flash over its whole extent of surface. The mirrors are screwed on to tripod stands, the stand for the signalling mirror having a sighting bar with a frame of cross wires at the end, by means of which the alignment can be accurately taken by looking through a hole in the centre of the mirror. When this has been found a small white disc is put into a hole in the centre of the cross wire frame, and a black disc in the central hole in the signalling mirror, or, if two mirrors are used, the white disc in the signalling and the black disc in the sun mirror. The flash is then brought on the true line by making the shadow corresponding to the black disc fall on the white one; this is accurately obtained by means of slow-motion screws in a vertical and horizontal

direction, by which means also the sun's apparent motion is continually corrected. The obscuration is effected by a screen placed on a tripod in the alignment of the flash, pivoted horizontally, and worked by a handle. In the heliograph patented by Mr Mance the mirrors are circular, the obscuration being effected by giving a small angular motion to one of the mirrors, causing the reflected beam to travel through twice the angle and completely disappear from the distant point. This is more easily manipulated than obscuration by a screen. Its working is made very similar to that of an ordinary Morse key. The sun's motion is corrected by slow-motion screws, and the arrangements for directing the flash are very similar to those in the heliostat. Two tripod stands are employed: one is for the signalling mirror; the other in single working carries a jointed arm, fitted with a small white metal tablet having a black spot on which is thrown the shadow from an unsilvered hole in the centre of the signalling mirror, while in duplex working a piece of paper in the centre of the second mirror answers the same purpose.

In addition to its usefulness as a signalling instrument, the heliograph has been found of great service in defining exactly distant points for large surveys, such as the triangulation of India. For this purpose it was constantly employed by the late astronomer-royal at the Cape, Sir T. Maclear, in his verification of the arc of the meridian. (p. a.)

HELIOPOLES. See BAALBEK and EGYPT, vol. vii. p. 769.
HELIOPTROPE, or **TURNSOLE**, *Heliotropium*, L. (Greek, *ἡλιότροπον*, i.e., a plant which follows the sun with its flowers and leaves, or, according to Theophrastus, *Hist. Plant.*, vii. 15, which flowers at the summer solstice), a genus of usually more or less hairy herbs or undershrubs of the tribe *Heliotropiceae* of the natural order *Boraginaceae*, having alternate, rarely sub-opposite leaves; small white, blue, or blue flowers, in terminal or lateral one-sided simple or once or twice forked spikes, with a calyx of five deeply-divided segments, a salver-shaped, hypogynous, 5-lobed corolla, and entire 4-celled ovary; fruit 2- to 4-sulcate or lobed, at length separable into four 1-seeded nuts, or into two hard 2-celled carpels; and seeds generally with a scanty albumen. In some species the cone surmounting the stigma is bearded. The heliotropes are indigenous mostly to tropical and subtropical regions, but a few species are natives of Europe, as *H. europæum*, L., which is also a naturalized species in the southern parts of North America. *H. indicum*, L. (of the section *Heliphytum*, D.C.), is to be met with in equinoctial Africa, America, and Asia, but apparently not in Australia. Of 33 Australian species of *Heliotropium* that have been described, 16 are endemic. The common heliotrope of English hothouses, *H. peruvianum*, L., popularly known as "cherry-pie," is on account of the delicious odour of its flowers a great favourite with florists. It was introduced into Europe by the younger Jussieu, who sent seed of it from Peru to the royal garden at Paris. About the year 1757 it was grown in England by Mr P. Miller from seed obtained from St Germain. The plant has been known to occur with double flowers (Masters, *Yeg. Perat.*, p. 610, Ray Soc., 1869). *H. corymbosum*, Ruiz et Pav., which was grown in Hammamsmith

Heliotropium suaveolens.

HELLEBORE (Greek, ἡλέβορος; Modern Greek also *erakopis*; German, *Nieswurz*, *Christwurz*; French, *hélébore*, and, in the district of Avranches, *herbe enragée*), *Helleborus*, L., a genus of plants of the natural order *Ranunculaceae*,¹ natives of Europe, Western Asia, and North America. The leaves² are palmate or pedate (BOTANY, vol. iv. p. 111, fig. 108), are usually solitary, and have five persistent petaloid sepals, within the circle of which are placed the minute gland-like tubular petals, the nectaries of Linnaeus, of the form of a horn with an irregular opening, and representing, according to Baillon (*Nat. Hist. of Plants*, i. 13, 1871), "the lower or outermost stamens transformed into stamens." The stamens are very numerous, and are spirally arranged; and the carpels are variable in number, sessile or stipitate, and slightly united at the base, and pubescent by ventral suture (vol. iv. 141, 149).

Helleborus niger, L., thuck Hellebore, or, as from blooming in mid-winter it is named, the Christmas Rose (Ger., *Schneeweiss Nieswurz*; Fr., *Rose de Noël*), is found in southern and central Europe, and with other species was cultivated in the time of Gerard (see *Herbalt*, p. 977, ed. Johnson, 1538) in English gardens. Its knobby bracted rhizome is blackish-brown externally, and, as with other species, gives origin to numerous straight roots. The leaves are nullent, coriaceous, succul., distinctly petiole, dark green above, and lighter below, with 7 to 9 segments, and long petioles. The sepals, which end the branches of the rhizome, have a loose entire bract at the base, and terminate in a single flower, with two bracts,

Helleborus niger. 1, Vertical section of flower; 2, nectary, style and fruit view (not also).

from the axis of one of which a second flower may be developed. The flowers have 5 white or pale-rose, eventually greenish sepals, 15 to 18 lines in breadth; 8 to 13 tubular green petals containing a sweet liquid secretion; and 5 to 10 free carpels.

Varieties of Black Hellebore are *H. niger minor*, or *H. angustifolius*, and Giant Hellebore, distinguished as *H. niger major*, *maximus*, *giganteus*, and *grandiflorus*, or as a distinct species, *H. alifolius*, *H. foetidus*, &c. The Shining Hellebore, in Westerland Volon-grass, known also from the shape of its leaves, as Bear's-foot (*Fr., Pied de Griffon*), is a native of England, where, like *H. viridis*, it is confined chiefly to limestone districts; it is common in France and the south of Europe. Its leaves have 7- to 11-toothed divisions, and the flowers are in panicles, numerous, cup-shaped, and drooping, with many bracts, and green sepals tinged with purple, alternating with the five petals.

¹ On this plant known as White Hellebore (*Veratrum album*) and American White Hellebore, commonly called "Green Hellebore" (*V. viride*), which are members of the natural order *Veratraceae*, see *Veratrum*.

² On the development and structural relations of the leaves, see A. Trecul, *Ann. Sci. Nat., Bot.*, ser. III., tom. xx, 260, 268, pl. 23, figs. 101-3, 1859; and *Cien. Zool. Sci. Bot. de France*, III. 632, 1868.

³ On the petals of the hellebores, see J. B. Payson, *Traité d'opponibilité comparée des Pl. min.*, pp. 256-260, 1857. In the opinion of Baillon (*op. cit.*, pp. 15-21), the groups *Branchia* and *Cypripis*, from the structure of their flowers, as also strictly *Isopyrum* and *Xanthoxylum*, should not be generically separated from *Helleborus*.

H. viridis, L., or Green Hellebore proper, ranges from England, where it is probably indigenous in some of the southern and eastern counties, to Spain and Italy, and even it is said to Turkey. It has bright yellowish-green flowers, 2 to 4 on a stem, with large leaf-like bracts. Brancialis and Boeck (16th century) regarded the plant as the Black Hellebore of the Greeks.

The radical leaves of *H. viridis* and its varieties, as also of *H. multiflorus*, Visian, *H. purpureus*, W. & K., *H. cyclophyllus*, Boiss., and several allied forms, wither in winter. In *H. scaberrimus*, Ag. (Boissier, *Fl. Orient.*, i. 60), a native of Syria, the flower-stem bears 4 to 5 flowers, and the carpels are much compressed laterally, and when ripe, united half way up, as in certain *Nigella*. *H. helidius*, Soland (*H. eructifolius*, Viv., *tripetalus* Mill., and *viridis* and *triphyllus*), Holly-leaved Hellebore, found in the Dalmatian Islands, and in Corsica and Sardinia, is remarkable for the handsomeness of its foliage. *H. androgynus*, Braun, which has purplish-white flowers, occurs in Bithynian Phrygia. *H. olympicus*, Linn., perhaps a variety of it, *H. cyclophyllus* (Boiss., *Fl. Orient.*, i. 61), a Grecian species, has ovato-orbicular green sepals. *H. orientalis*, Lam., *Eruc.*, III. 22 (*H. poutica*, Braun, see Boiss., *op. cit.*), indigenous to Macedonia, Thrace, the vicinity of Constantinople, and northern Asia Minor as far east as Tiflis, has leaves pubescent below, and 7 to 9 segments, and sepals bearing 8 to 5 flowers, with white or very sepals. Allied to it are *H. atrovirens*, W. & K., of which Koch regards *H. atrovirens* as a variety, and *H. caucasicus*, Koch, having green and purplish-green sepals respectively.

Hellebores may be grown in any ordinary light garden mould, but thrive best in a soil of about equal parts of turfy loam and well-rotted manure, with half a part each of fibrous peat and coarse sand, and in moist but thoroughly-drained situations, more especially where, as at the margins of shrubberies, the plants can receive partial shade in summer. For propagation, cuttings of the rhizome may be taken in August, and placed in pans of light soil, with a bottom heat of 60° to 70° Fahr.; hellebores can also be grown from seed, which must be sown as soon as ripe, since it quickly loses its vitality. The seedlings usually blossom in their third year. The exclusion of frost favours the production of flowers; but the plants, if forced, must be gradually inured to a warm atmosphere, and a free supply of air must be afforded, without which they are apt to become much affected by greenfly. The flowers on one plant of *H. niger major* in Mr B. Hooker's garden at Bradfield, Berks, about the end of January 1878, numbered nearly 500 (*Gard. Chron.*, 1878, i. 145). For potting, *H. niger* and its varieties, and *H. orientalis*, *atrovirens*, and *olympicus* have been found well suited. After lifting, preferably in September, the plants should receive plenty of light, with abundance of water, and once a weak liquid manure, not over-strong. The flowers are improved in delicacy of hue, and are brought well up among the leaves, by preventing access of light except to the upper part of the plants. Of the numerous species of hellebore now grown, the deep-purple-flowered *H. colchicus* is one of the handsomest. *H. atropurpureus*, introduced in 1844, blooms in March or at the end of February, and may be effectively used in flower borders to succeed haphenates, scillas, and crocuses (Maund, *Bot. Gard.*, v. pl. cxviii., fig. 2). Hellebores having variously coloured spreading or bell-shaped flowers, spotted with crimson, red, or purple, were grown by Bauer, late superintendent of the Berlin University Garden, about the year 1851, as the result of crossing *H. guttatus*, Braun, and *H. purpureus*. Other fine varieties have been obtained by Bouclé, his successor, from crosses with *H. olympicus*, and by Carl Heinemann from *H. guttatus* and *H. abachianus*.

The rhizome of *H. niger* occurs in commerce in irregular and nodular pieces, from about 1 to 3 inches in length,

⁴ According to Regel, *H. orientalis*, *caucasicus*, *colchicus*, *androgynus*, *olympicus*, *guttatus*, and *abachianus* should all be reduced to one species. Koch (*Gard. Chron.*, 1874, i. 118) regards the Hungarian *H. quercifolius*, W. & K., and the Caucasian *H. colchicus*, Reg. (= *H. porphyrodon*, Braun), as varieties of the last-named. The "*H. abachianus*" of Belgian florists is stated by M. J. L. Le Bé (Monog. des Helleb., "Le Belgique Horticult.", vi. 331) to be merely a variety of *H. intermedius*, Guss.

ship from her seat, and to be carried away by the current hence the name *Hellespontus*, or "Sea of Hellos."

HELLIN (*Ilunium*), a town of Spain, in the province of Albracca, is situated on the slope of the Sierra de Segura, 35 miles S E E of Albacete. It is a clean and well built town, and possesses the remains of an old Roman castle and a beautiful parish church, the masonry and marble pavement at the entrance of which are worthy of special notice. The principal manufactures are sulphur obtained from the celebrated mines about 13 miles distant, earthenware, linens, cloth, hats, leather, and oil. Hellin was sacked by the French under Montbrun, and was the point where Joseph and Bonaparte parted with Suchet after Mamont's rout at Salamanca. The population is about 6000.

HELMERS, J. W. F. van der (1767-1813), Dutch poet, was born at Amsterdam, March 7, 1767. His early poems *Night* (1788) and *Souates* (1790) were tame and sentimental, but he woke up after 1803 to the melancholy condition of the Fatherland, and determined, in company with his friend Cornelius Loots, to rouse national feeling by a burst of patriotic poetry. His poems, published in 1800 and 1810, but especially his great work *The Dutch Nation* (1812), created great enthusiasm and enjoyed immense success. Helmers died at Amsterdam, February 26, 1813. He was a fiery, somewhat turgid writer, but by no means devoid of force, but owing his success mainly to the integrity of his patriotism and the opportunity of moment which he sounded his counterblast to the French oppression. His posthumous poems were collected in 1817.

HELMET, or **HELM** (Anglo-Saxon, *helm*, Italian, *Elmo*, French, *Heaume*, Icelandic, *Helming*), is the term used in a general sense to include the various forms of head defences which were either made in solid metal or of metal plates. The form of helmet used among the Assyrians, as shown by the monumental sculptures, was a close fitting skull-cap, round or conical, sometimes surmounted by a crest rising from the summit of the cone and curving forwards in a semicircular form. The Greek helmet was also in its simplest form a skull-cap, covering the head in front above the level of the eyes, but reaching down to the nape of the neck from ear to ear. Another form had this lower part prolonged and carried round so as to cover all above the shoulders with the exception of a slit in front, partly protected by a nose-piece. Occasionally jugged cheek-pieces were added to the skull-cap, and the upper part of the casque was sometimes prolonged into a conical shape with a crest curving forwards, or surmounted by a ridged prominence on which was fastened a flowing crest of horsehair. The Greek helmets are often represented as highly decorated, and many examples of the different forms and their varieties of decoration occur on the painted vases, the gems, and the coins. The Etruscan helmet differed but slightly from that of the Greeks. It was more conical in form, and often furnished with horns or wings in place of a crest. The Roman helmet was usually a skull-cap, with or without crest, and often plain and undecorated. The Gaulish helmet, of which a beautiful specimen was obtained from an Iron Age burial at Berru in Maine in 1872, was of hammered iron, conical in shape, terminating in an ornamental apex, and having a richly decorated border round the lower part. Conical helmets of an earlier character found at Thell and Auxonne have been assigned to the Age of Bronze. A silver helmet of the Early Iron Age, consisting of a skull-cap with a mask for the face fastened together by a huge, which was found in the Thorsberg floss in South Jutland, is the only specimen known of the early Teutonic helmet. An Anglo-Saxon helmet of iron, shaped like a skull-cap, and formed of ribs or flat strips of metal, covered with plates of horn, and surmounted with the figure of a boar, was found in a tumulus

at Benty Grange in Derbyshire. Such horn-crowned helmets are referred to in the Anglo-Saxon poem of Beowulf. The helmets worn by the Normans and Saxons at the time of the Conquest, as shown in the Bayeux tapestry, were conical in shape with a projecting nasal. The earliest known example of a date subsequent to the Norman Conquest is one which was discovered in the church of Faversham, and is now in the Musée d'Artillerie at Paris. It preserves the conical top of the earlier Norman headpiece, but has a barrel-shaped body, covering all the head and face with the exception of a vertical slit partially protected by a projecting nasal, and having transverse apertures on either side for the eyes. This barrel shape, with flattened instead of conical top, continued in use during the 13th century in England, although the conical cap with the nasal appears on the great seals of the Scottish kings down to the time of Alexander II. The helm of Edward the Black Prince (died 1370), which still hangs over his tomb in Canterbury Cathedral, has the top shaped like a truncated cone and the lower part more oval than barrel-shaped, the aperture for sight taking the form of a transverse slit between the upper and lower parts of the helm. In the lower portion the perforations for breathing are arranged in the form of a crown on both sides. The helm of Henry V. (died 1422), which hangs with his saddle and shield above his tomb in Westminster Abbey, is lower in the crown, more rounded to the shape of the head, and the central nasal or projection for sight is protected by the projection of the lower part beyond the line of the upper. The helm of King Henry VI, which was suspended over his tomb in St George's Chapel, Windsor, has the lower part contracted to the form of the neck and rounded to the shape of the shoulders. The *oculorum*, which is wide, is protected by a series of curved bars riveted across it. The helm of Edward IV (died 1483), which was also suspended in St George's Chapel, exhibits a still greater shaping to the form of the neck and shoulders, the top is rounder, and has a spike for a crest. In the end of the 15th century the great helm was superseded by the smaller headpiece with movable visor and beaver or clumpies and neck guard, which is properly styled a helmet. Other varieties of headpieces were the basinet, of a plain oval form pointed at the top and somewhat compressed on the sides, having holes at the bottom for the attachment of the camail or gorget of chain mail. The basinet was sometimes worn alone and sometimes under the helm. It was succeeded in the 15th century by the salade, a lighter skull cap with the hinder part projecting, and occasionally a movable visor. The ainet, the burgonet, and the casque are varieties of the lighter form of head piece, packing more or less of the skull-cap form, while the morion and the chapeau de fer were distinguished by their flattened brows.

HEILBONDT, a town of the Netherlands, in the province of North Brabant, to the left of the river Aa, with a station (since 1860) on the state railway between Venloo and Eindhoven. The castle of Holmوند remains a beautiful specimen of the architecture of the 15th century, and among the other buildings of note in the town are the spacious church of St Lambert, the Reformed church, and the town house. Cotton-weaving on a very extensive scale, dyeing, iron-founding, brewing, soap-boiling, and tobacco dressing are the chief industries of the commune. The population of the town proper in 1870 was only 5280, but the commune, which includes several suburbs, had about 6600.

HEILBONDT is also mentioned as a town in 1384, but it may possibly be identical with a certain Heilmond or Hailmont which appears in the 12th century. In the middle of the 13th century it was the favourite residence of Mary of Brabant, queen of the Romans. Fortified shortly after the attack of the people of Brabant in 1548, it continued a place of military importance till the

peace of Munster. The occupation of the town by the duke of Parma in 1578, its recovery by the states of Holland in 1583, its capture by the count of Hohenlohe in 1588, and the seizure of the castle by Count Fiedrich of Nassau are the chief events in its military annals. In 1814 the town received the right of parliamentary representation, but it shares also lost the privilege.

HELMONT, JEAN BAPTISTE VAN (1577-1644), was born at Brussels in 1577. He was educated at Louvain, and began the study of natural science under the Jesuits in that city. Their hard and dry philosophy, however, had few attractions for a nature so ardent and imaginative as his. Turning for relief to other systems, he found no rest except in the mysticism of A. Kempis and Tauler. From them he learned that wisdom is the gift of the Supreme Being, that it must be obtained by prayer, and that we must renounce our own will if we wish to participate in the influence of the divine grace. From this time he began a life of exemplary meekness and humility, made over his property to his sister, and retired from the high society in which he had hitherto walked. He devoted himself to the study of medicine, read carefully all that had been written on the science, and felt dissatisfied with its method and results. He then turned to Paracelsus and the alchemists, and conferred a real boon on humanity by rescuing chemical science from the erratic absurdities of the post-Paracelsian alchemists, and applying it to more philosophical principles. He graduated as M.D. in 1599, and, after travelling through France and Italy, Switzerland and England, married a rich lady of Brabant, by whom he had several children. He died in Holland in 1644, in the sixty-seventh year of his age. Science is under real obligations to Van Helmont, though the greater part of his speculations presents a curious mixture of mystical philosophy and acute chemical research. To him is due the invention, or at least the first application, of the term "gas" in the sense in which it is now used. He also discovered that gas was disengaged in abundance by the application of heat to various bodies, and during the solution of various carbonates and metals in acids.

Van Helmont's works were published at Amsterdam in 1648 by his son Marinus, a more accurate and complete edition is that of Rivin, 1652. The fullest account of his speculations is given in Bruner and Sieber, *Entwurf einer Geschichte der Physiologie* (1819-20). His *vi* See *de Spiss, Elementi System de Medicin*, 1840. Rommelaere, *Bijsde van J. v. Helmont*, 1868. Van Helmont's mystical philosophy and alchemy appeared in even greater confusion in the works of his youngest son, Franz Meinicus, who was born in 1618 and died, after a somewhat adventurous and troubled life, at Berlin in 1698. His chief works are *Cabbalistic Denksatze*, 1677; *Paradoxa Discursus*, 1686; and *Opuscula Philosophica*, 1690.

HELMSTADT, or HELMSTADT, a town of Germany in the duchy of Brunswick, is situated on the railway from Magdeburg to Brunswick, 23 miles E. of Brunswick. It is the seat of a circle directorate, and of a circle and a district court. The principal buildings are the *Juleum* in the Byzantine style, founded by Duke Julius of Brunswick in 1575 for the university which was abolished in 1809, and now containing an old library of 40,000 volumes, the church of St Stephen's, dating from the 12th century, the Lutheran female institution, with a beautiful church in the Roman style, and the Catholic church and ruined monastery of St Ludger. The educational institutions include a gymnasium, two city schools, an agricultural school, and two female schools of the higher grade. The principal manufactures are yarn, soap, tobacco, sugar, ritual, earthenware, and tobacco pipes. Not far from the town there is an iron mineral spring especially efficacious in gouty affections. Near it a monument has been erected to those who fell in the Franco-German war of 1870-71, and in the town there is also a monument to those who fell at Waterloo. The population in 1875 was 7783.

Helmsstedt originated in connexion with the Ludger monastery, founded by Ludger, first bishop of Munster, in the year of the 8th century. It obtained town rights in 1089, and although destroyed by the schism of Magdeburg in 1190 it was soon

rebuilt. In 1457 it joined the Hanse, and in 1490 it came into the possession of Brunswick. See Kunhardt, *Bildung und Geschichte der Universität Helmstedt*, 1797; Lüdowig, *Geschichte und Beschreibung der Stadt Helmstedt*, 1852; *Geschichte der Universität Helmstedt*, *Friedr. Carolina van Helmsstedt*, 1870.

HELOISE See **ABELARD**

HELOTS, in Grecian antiquity, were the serfs or bondsmen of the Spartans. The most probable of the various explanations of their origin seems to be that they were the early aborigines of Laconia, who at the time of the Dorian invasion were reduced to slavery by the conquerors. The name is perhaps best derived from the root *helo*, found in *helois*, *hlois*, and other words. The Helots were the lowest class of the inhabitants of Sparta, but those of them who were emancipated formed the class of *Neodamodeis*, next in political rights to the Spartan citizens themselves. The *Mothones* or *Mothakes* were domestic slaves who had been brought up along with the young Spartans, and afterwards liberated. The Helots were the property of the state, which alone had the right of emancipating them, although it made over their services to individuals. They were attached to the soil—*adscripti glebe*—and could not be sold away from it. They tilled the land which was allocated to them in the proportion of one lot to several families, and for each lot they paid to their masters an annual rent of 85 medimni of barley, and a quantity of wine and oil. They were also employed on public works, and performed all domestic service. In time of war the Helots generally served as light-armed troops, but when on special emergencies they fought as *hoplites*, they were usually rewarded with their freedom. The first occurrence of this kind was under Brasidas in 424 B.C. In the fleet the great bulk of the sailors were Helots. Although every care was taken to distinguish the serf from his lord, even in the matter of dress, the accounts of the cruel treatment of the Helots by the Spartans only hold true of the later history of Laconia. The condition of the Helot was better than that of a slave in other Greek states, for being a sort of the soil, he was not wholly at the mercy of his master, and there was a legal way whereby, after many stages, he could eventually attain freedom and citizenship. After the Messenian war, however, when the multitude of the Helots made them formidable to the diminished numbers of the full citizens, there is no doubt that very cruel measures were adopted against them. The evidence is strong that the *Cypriotes*, instituted ostensibly to man the Spartan youth to husbandry, was really intended to reduce the number of the full citizens by assassination, and we know from Thucydides (ii. 80) that on one occasion 2000 Helots were treacherously massacred by the Spartan citizens. At the close of the second Messenian war (608 B.C.), the conquered Messenians were classed with and treated as the Helots, till Epaminondas restored them to their native country after the battle of Leuctra (371 B.C.).

For further details see Plutarch's *Life of Lysurgus*, Thirlwall's *History of Greece*, Grote's *History of Greece*, Muller's *History of the Dorians*, and Heiman's *Political Antiquities of Greece*.

HELPS, SIR ARTHUR (1813-1875), fourth and youngest son of Thomas and Ann Frisquet Helps, was born at Balham Hill, in the parish of Stretcham and county of Surrey, on the 10th of July 1813. His father was then and for many years afterwards head of a large mercantile house in the city of London, and for the last thirteen years of his life treasurer of St Bartholomew's Hospital. His mother was the only surviving child of John, fourth son of the Rev. Charles Hukneth, M.A., of Wimsont. After the usual preliminary training at Eton, young Helps went to Trinity College, Cambridge, passing as B.A. in 1835, when he came out 31st wrangler in the mathematical tripos, and taking his M.A. degree in 1839. Although he took no high honours at the university, and indeed he

had not health sufficiently robust, even if he had possessed the ambition, to achieve them,—he was recognized by the ablest of his contemporaries there as a man of superior gifts, and likely to make his mark in after life. They showed this by electing him as a member of the Conversazione Society, better known as the Apostles, a society which had been established in 1820 for the purposes of discussion on social and literary questions by a few young men attracted to each other by a common taste for literature and speculation. A body which in its early days included the names of Charles Bulfinch, Frederick Maurice, Richard Chenevix Trench, Monckton Milnes, Arthur Hallam, and Alfred Tennyson had in it every element to make its gatherings delightful as well as useful. To be elected into its limited circle was a distinction of which Arthur Helps was proud then and to the close of his life, and familiar as he was with the best and most intellectual society of his time, the social hours passed year by year with the Cambridge Apostles were always counted by him among his happiest, both in anticipation and in remembrance.

In the discussions of these and later days Helps may have found the suggestions for the dialogues of the *Friends in Council*, in which his genius appears at his best. But his first literary effort, which appeared under the title of *Thoughts in the Closets and the Crowd* in 1835, the year he took his B.A. degree, assumes a very different but scarcely less ambitious form, that of a series of epigrams upon life, character, politics, and manners. As a rule, such things are only valuable when they come as the fruits of wide experience and matured thought. Still in this volume are to be found passages which may take their place beside the sayings of Vauvenargues, Chamfort, and other masters of aphorism of the second rank, and are quite equal in quality to the many pithy quotable sayings scattered through Helps's later works.

Soon after leaving the university, where he had established many valuable friendships, Arthur Helps became private secretary to Mr Spring Rice (afterwards Lord Monteagle), then chancellor of the exchequer in Lord Melbourne's administration. This appointment he filled till 1840, when he went to Ireland as the private secretary of Lord Morpeth (afterwards earl of Carlisle), then the chief secretary of state for Ireland, where he remained until his principal left Ireland in 1841, on the Government passing from Lord Melbourne into the hands of Sir Robert Peel. In the meanwhile (28th October 1836) Helps had married Miss Beesy Fuller, a young Irish lady. He was also appointed one of the commissioners for the settlement of certain Danish claims which dated so far back as the siege of Copenhagen, but with the fall of the Melbourne administration his official experience closed for a period of nearly twenty years. The character which he had established for himself by his tact, sagacity, and business habits was not, however, forgotten by his political friends. And combined as these qualities were with an admirable manner which invited confidence while it repelled intrusion, and with a reticence and discretion on which absolute reliance could be placed, his fitness for official life was unmistakable. When therefore the clerkship of the Privy Council became vacant in 1860, on the resignation of the Hon W. L. Bathurst, he was recommended for the appointment by his old friend Lord Granville, who knew that for ability, tact, and discretion it could not be in safer hands.

During his early official career Helps cultivated literature with varying success. His *Essays written in the Intervals of Business*, published in 1841, and his *Claims of Labour, an Essay on the Duties of the Employers to the Employed*, published in 1844, continue to interest, and are likely to keep their place in well-selected libraries. But two plays, *King Henry the Second, an Historical Drama*, and *Catherine*

Douglas, a Tragedy, both published in 1843, have no particular merit. Neither in these, nor in his only other dramatic effort, *Outlets the Sea*, published in 1858, a work far superior, however, to his earlier efforts of the same kind, are to be found the sense of dramatic situation and movement, the sharp outlines and contrast of character, or the fitness and concise force of diction which alone justify the selection by an author of the dramatic form as the vehicle for his thoughts. Helps possessed, however, just enough dramatic power to give life and individuality to the dialogues which he introduced with excellent effect to enliven many of his other books. His first effort in this direction was in *Friends in Council, a Series of Readings and Discussions thereon*, published in 1847 and 1851. The plan of this book seems to have been suggested by a passage in Bacon's essay *Of Discourse*, which appears as the motto of it: "It is good in discourse and speech of conversation to vary and intermingling speech of the present occasion with arguments, tales with reasons, asking of questions with telling of opinions, and jest with earnest, for it is a dull thing to tie, and, as we say now, to jade anything too far." The variety and conflict of opinion, the play of characters, the flashes of humour, got by submitting the formal essays on social and moral questions which made the staple of these volumes to be criticized and pulled to pieces by the imaginary personages, who, under the names of Milverton, Ellesmere, and Dunford, grew to be almost as real to Helps's readers as they certainly became to himself, gave a special charm to a book which, by its richness of suggestion, its sweetness of tone, and beauty of style, made for its author a high and enduring reputation. The same expedient was resorted to for the discussion of the ideas of social and philanthropic improvement on which Helps's mind was always at work, in a second series of *Friends in Council*, published in 1850, and again in *Conversations on War and General Culture*, published in 1871. The old familiar speakers, with others added, also appeared in his *Realms*, and finally in what certainly must always rank as the best of its author's later works, *Talks about Animals and their Masters*, published in 1873.

The subject of slavery was one which had a peculiar fascination for Helps. A long essay is devoted to it in the first series of *Friends in Council*. This was subsequently elaborated into a work in two volumes published in 1848 and 1852, called *The Congresses of the New World and their Bondsmen*. Helps's interest in the subject led him into further investigations into the history of the conquest of America by the Spaniards, and he went to Spain in 1847 for the special purpose of examining the numerous MSS bearing upon the subject at Madrid. The fruits of these researches were embodied in an historical work based upon his *Congresses of the New World*, and called *The Spanish Conquest in America, and its Relation to the History of Slavery and the Government of Colonies*. This appeared in four volumes during the years 1855, 1857, and 1861. No pains were spared by its author to secure the most scrupulous accuracy as to the facts with which he dealt. He had found, as most inquirers into the sources of history have found, that this accuracy is rarely to be met with in accepted histories. On this point he was determined that he should not be open to censure, and so anxious was he that fact should not be coloured or distorted by imagination that he deliberately resisted the temptation to use the picturesque method of treatment by which other writers on the same subject have secured popularity. The excess of this work with the public was injured by other peculiarities. History, like fiction, will not bear to be written with an obtrusively moral purpose, as this book was written. Its merits in a literary point of view were also diminished by the author's tendency to suspend the onward movement of the narrative,

The town is well laid out, with long and wide streets running at right angles. The houses are large and well built, and the principal square contains several fine buildings, as the senate-house, the university, and a magnificent church. Helsingfors has a colossal Russo-Greek cathedral, a seminary, botanical gardens, an observatory well supplied with both astronomical and magnetic instruments, a beautifully decorated theatre, and other handsome public buildings. The university, removed from Åbo in 1827, has 4 faculties, 53 professors, and about 900 students, and possesses a museum with extensive natural history and mineralogical collections, an ethnological collection, and a chemical laboratory. There are scientific, literary, and other learned societies, a normal lyceum, polytechnic institute, school for the blind, school of navigation, asylum for the insane, hospitals, and other educational and charitable institutions. Helsingfors is the seat of the governor general of Finland, the imperial senate, and all the central offices of the grand-duchy. In the hall of the senate-house is a splendid throne for the emperor, in the interior-house the various branches of the assembly meet, and there also are the remains of the library saved from the fire of Åbo, and containing 10,000 volumes. Helsingfors has several machine manufactures, (one with 850 workpeople), and produces at the rate of £100,000 per annum, it has also porcelain, faience, sugar, and tobacco factories. There are two considerable harbours, with a handsome granite quay extending along the front of the town. In 1870 the population was 32,113, in 1879 about 10,000.

Helsingfors is the largest import trade in Finland, consisting mainly of wool, colonial and manufactured wares, silk, wine, &c., amounting in 1874 to £1,697,714, in 1875 to £1,718,487. The exports consist chiefly of wooden wares, the total amounting to £1,110,427 in 1878. Of the imports £137,100 came from, and of the exports £37,511 went to, England. In 1874 559 vessels of 178,717 registered tons entered the port, and in 1878 713 vessels of 74,397 tons, in 1875 950 of 195,519 tons cleared, and in 1878 825 of 112,170 tons. In 1870 the port possessed 43 vessels (18 of them steamers) of 1129 tons.

Helsingfors was founded by Gustavus Vasa in the 16th century, about 3 miles N.E. of the present site, to which it was removed by Queen Christina of Sweden in 1642. In 1742 it was the scene of the capitulation of the Swedes under Lewnawitz, but in 1749 the fortress of Sveaborg was erected by the Swedish high admiral, Count Lihnevald, who at his own request was afterwards buried within its walls. In 1808 Admiral Cronstedt transferred the place to the Russians under General Sacken. A combined squadron of the French and English bombarded Sveaborg in 1808.

See *Blaumen, Helsingfors Uppgiften om Helsingfors*, 1871.

HELST, BARTHOLOMEW VAN DER, was born in Holland at the opening of the 17th century, and died at Amsterdam in 1670. The date and place of his birth are uncertain, and it is equally difficult to confirm or to deny the time-honoured statement that he was born in 1613 at Amsterdam. It has been urged indeed by competent authority that Van der Helst was not a native of Amsterdam, because a family of that name lived as early as 1607 at Haalem, and pictures are shown as works of Van der Helst in the Haalem Museum which might tend to prove that he was in practice there before he acquired repute at Amsterdam. Unhappily Bartholomew has not been traced amongst the children of Severyn van der Helst, who married at Haalem in 1607, and there is no proof that the pictures at Haalem are really his, though if they were so they would show that he learnt his art from Frans Hals and became a skilled master as early as 1631. Schelomo, a very competent judge in matters of Dutch art chronology, supposes that Van der Helst was a resident at Amsterdam in 1636. His first great picture, representing a gathering of civic guards at a brewery, is variously assigned to 1639 and 1643, and still adorns the town-hall of Amsterdam. His noble portraits of the burgo-master Bicker and Andries Bicker the younger, in the gallery of Amsterdam, of the same date no doubt as Bicker's wife

lately in the Ruhl collection at Cologne, were completed in 1643. From that time till his death there is no difficulty in tracing Van der Helst's career at Amsterdam. He acquired and kept the position of a distinguished portrait-painter, producing indeed little or nothing besides portraits at any time, but founding, in conjunction with Nicolaas de Holt Stokade, the painters' guild at Amsterdam in 1651. At some unknown date he married Constance Reynst, of a good patrician family in the Netherlands, bought himself a house in the Doelenstrasse, and ended by earning a competence. The likeness of Petrus Potter at the Hague, executed in 1654, and his partnership with Backhuysen, who laid in the background of some of his pictures in 1668, indicate a constant companionship with the best artists of the time. Waagen has said that his portrait of Admiral Kortenaar, in the gallery of Amsterdam, betrays the teaching of Frans Hals, and the statement need not be gaudied, yet on the whole Van der Helst's career as a painter was mainly a protest against the systems of Hals and Rembrandt. It is needless to dwell on the pictures which preceded that of 1648, called the Peace of Munster, in the gallery of Amsterdam. The Peace challenges comparison at once with the so-called Night Watch by Rembrandt, and the less important but not less characteristic portrait of Hals and his wife in a neighbouring room. Sir Joshua Reynolds was disappointed by Rembrandt, whilst Van der Helst surpassed his expectation. But Buijs asked whether Reynolds had not already been struck with blindness when he ventured on this criticism. The question is still an open one. But certainly Van der Helst attracts by qualities entirely differing from those of Rembrandt and Frans Hals. Nothing can be more striking than the contrast between the strong concentrated light and the deep gloom of Rembrandt and the contempt of chiaroscuro peculiar to his rival, except the contrast between the rapid sketchy touch of Hals and the careful finish and touching of Van der Helst. The Peace is a meeting of guards, to celebrate the signature of the treaty of Munster. The members of the Doele of St George meet to feast and congratulate each other not at a formal banquet but in a spot laid out for good cheer, where De Wit, the captain of his company, can shake hands with his lieutenant Warven, yet hold in solemn state the great drinking-horn of St George. The rest of the company sit, stand, or busy themselves around, — some eating, others drinking, others carving or sewing — an animated scene, on a long canvas, with figures large as life. Well has Buijs said the heads are full of life and the hands admirable. The dresses and subordinate parts are finished to a nicety without sacrifice of detail or loss of breadth in touch or impact. But the eye glides from shape to shape, arrested here by expressive features, there by a bright stroke of colour, nowhere at rest because of the lack of a central thought in light and shade, harmonies, or composition. Great as the qualities of Van der Helst undoubtedly are, he remains below the line of demarcation which separates the second from the first-rate masters of art.

These times are very numerous, and almost uniformly good, but in his later creations he is quite power, and though infinitely careful, he becomes grey and woolly in touch. At Amsterdam the four regents in the Welkhuys (1650), four syndics in the gallery (1656), and four syndics in the town hall (1667) are masterpieces, to which may be added a number of fine single portraits. Rotterdam, notwithstanding the fire of 1842, still boasts of three of Van der Helst's works. The *Flagge*, as we saw, owns but one St Petrusburg, on the other hand, possesses ten or eleven, of various shades of excellence. The *Louvre* has three, Munich four. Other pieces are in the galleries of Berlin, Brunswick, Brussels, Calcutta, Vienna, Darmstadt, Dresden, Frankfurt, Gotha, Stuttgart, and Vienna.

HELSTON, a municipal and parliamentary borough, and market town of England, county of Cornwall, is situated on the declivity of a hill on the river Corber, 9 miles S.W.

of Falmouth. It consists of four main streets intersecting each other at right angles, at their junctions in the centre stands the market house. The principal other buildings are the church dedicated to St Michael and built by the earl of Golphin in 1763, the town-hall, the old coachage hall, the literary institute, the grammar school and the union work-house. The prosperity of the town is due to its being the centre of an extensive agricultural and mining district. The principal manufacture is shoes. At Porthleven, about 3 miles distant, a considerable export and import trade is carried on. Population of municipal borough (1871), 3797, of parliamentary borough (area 10,902 acres), 8760.

Helston is one of the original cinque towns. It was captured by Charles from King John, and the privilege was confirmed to it by Edward III of holding a market and fairs. It was made a corporate town by Elizabeth. Before the Reform Act of 1832 it returned two members to parliament, but it now returns only one.

HELVETIUS. See SWITZERLAND.

HELVETIUS, CLAUDE ADRIEN (1715-1771), was descended from a family of physicians, the first of whom, John Frederic Schweitzer (Latinized into Helvetius), migrated from Germany to Holland about the year 1649, and became physician to the prince of Orange. His later years were spent in the study of alchemy. His son, John Adrien, also a physician, went to Paris in the hope of establishing a sale for his father's drugs. He failed in this attempt, but was so fortunate as to introduce with the greatest success the use of ipecacuanha, then an unknown drug. The duchess of Chaulnes, whom he had treated successfully, introduced him to Colbert, who recommended the young physician to the dauphin, after which his reputation was firmly established. His son, John Claude Adrien, who embraced the same career with even greater success, was appointed inspector-general of the military hospitals of Flanders and first physician to the Queen Marie Leszczinska. He was remarkable for the generosity with which he received and visited poor patients who could pay him nothing. His son, Claude Adrien, the future author of *De l'Esprit des Loix*, showed as a boy little aptitude for study, but was fond of desultory reading. His father, who destined him for finance, placed him for a few years with his maternal uncle, M. D'Aimancourt, 'directeur des fermes' at Caen. There he learned all that was necessary for a profession so simple, and having plenty of spare time amused himself with writing verses and cultivating social graces. He was elected a member of the academy of Caen, and when he was only twenty-three years of age he had the singular good fortune to be appointed, at the queen's request, to a place as financier general, in other words, while still a very young man he was put into a post of great responsibility and dignity which was worth a hundred thousand crowns a year. Thus rewarded, young Helvetius proceeded to enjoy life to the utmost. He had every advantage except one, that of noble birth, he was the handsomest man of his time, he was possessed of a manner singularly charming, he was able to hold his own among the scholars and philosophers, and poets, he was skilled in all those arts cultivated by gentlemen, he was generous like his father, and his great fortune enabled him to gratify his love of giving, he had an inclination to letters, and was a friend of Fontenelle, Voltaire, and Montesquieu, besides being a patron of such writers as Marmontel, Saumais, and Sabatier. Probably there was no young man in Paris in the years 1740 and 1760 who occupied a more enviable position or was more entirely contented with his lot than this spoiled child of fortune, on whose name there rested but one blot, an almost morbid desire to excel. So far indeed did he carry this passion for distinction that he once danced on the stage of the opera under the mask and name of the public favourite Javillier.

As he grew older, his social successes and *bonnes fortunes* naturally ceased, the splendour of his youth had vanished,

he began to dream of other and more lasting distinctions. Montesquieu, he observed, had put mathematics in fashion, he himself would be a mathematician. Voltaire was illustrious for poetry, he too would be a poet. Montesquieu had made so brilliant a success with his *Esprit des Loix* that he himself would become a philosopher. The mathematical dream seems to have produced nothing, his poetical ambitions resulted in his poem called *Le Bonheur*, in which he develops the idea that true happiness is only to be found in making the interest of one that of all, his philosophical studies ended in the production of his famous book *De l'Esprit*, the composition of which occupied him for more than seven years. In the year 1761 he married, his wife being a niece of Madame de Gifford, the author of *Julie, ou le Nouveau Sémestre*, and he spent eight months in the year at his newly purchased estate of Val in Le Poëche, the remaining four months were given up to Paris and his duties of *maître d'hôtel* to the queen. It was characteristic of the man that as soon as he thought his fortune sufficient for his wants he gave up his post of financier general. The history of his life in the country is full of anecdotes which illustrate his generous and kindly disposition. He relieved the poor, sent physicians to the sick, mediated between those who quarrelled, encouraged agriculture, developed industry, and found happiness in the natural life of the French seigneur, being as great a stroller as any for his seigneurial rights. It was in 1758 that his book *De l'Esprit*, which was to be the rival of *L'Esprit des Loix*, appeared. It was so far successful at the very outset as to attract immediate attention and to arouse the most formidable opposition, at the head of which was the dauphin, son of Louis XV. The Sorbonne condemned the book, the priests persuaded the court that it was full of the most dangerous doctrines, and the author, terrified at the storm he had raised, wrote three separate retractions, yet, in spite of his protestations of orthodoxy, he had to give up his office at the court, and the book was publicly burned by the hangman. The violence of the attack upon the work, as much as its intrinsic merit, caused the whole world to read it, it was translated into almost all the languages of Europe, it was discussed in every literary circle. Yet the *Esprit des Loix* lives and is still studied with profit, while *De l'Esprit* has long since been forgotten. It is indeed difficult to understand that the work could ever have had any serious influence upon the thought of the time. Voltaire said it was full of commonplace, Buffon maliciously said that "Il n'y a rien de si commun que de dire du bien de moi et de mal de plus dans les sciences du roi," Rousseau declared that the very benevolence of the author gave the lie to his principles, Galiani thought that all the ideas in the book were borrowed from Diderot, Madame du Deffand said that Helvetius had said of such a storm by simply revealing the "great secret", Madame de Gifford averred that all the good things in the book had been picked up in her own salon.

As for the philosophy of the book, it belongs to the selfish school, the four discussions of which it consists have been thus summed up—(1) all man's faculties may be reduced to physical sensation, memory, comparison, judgment, are only feeling, our only difference from the lower animals lies in our external organization, (2) our interest, founded on the love of pleasure and the fear of pain, is the only spring of our judgment, our actions, our affections; we have no liberty of choice between good and evil, there is no such thing as absolute right—ideas of justice and equity change according to customs, (3) the inequalities of intellect do not depend on a more or less perfect organization, but have their cause in the unequal desire for instruction, and this desire springs from passions of which all men commonly well organized are susceptible to the same degree,

we can therefore all love glory with the same enthusiasm, and we owe all to education, (4) in this discourse the author treats of the ideas which are not attached to such words as *genius, integrity, talent, taste, good sense, &c.* It is sufficient to add that, although the book was republished after the author's death, it ceased to have any influence even during his own life.

In 1761 Helvetius visited England, and the next year, on the invitation of Frederick, he went to Berlin, where the king paid him marked attention. He then returned to his country estate and passed the remainder of his life in pious tranquillity. He died in 1771 at the age of fifty six, leaving behind him a widow, who died in 1800, and two daughters.

A set of supplements to the *De l'Esprit*, called *De l'Homme, de ses facultés intellectuelles et de son éducation*, is found among his manuscripts after his death, and was published, but created little interest. Editions of the work, however, appeared in 1772, 1773, and 1780. The complete works of Helvetius were published in 1771, 1777, 1781, 1791, 1795, and 1818. The best estimate of his work and place among the philosophers of the 18th century is that by Guizot (*Essays*, ii).

(W. E. B.)

HELVIDIUS PRISCUS lived in the 1st century, during the reigns of Nero, Galba, Otho, Vitellius, and Vespasian. In those evil days, he won the respect of all good men by his fearless love of freedom. Among the cunning and obsequious senators of Rome he dared to be sincere and outspoken. Tacitus says of him (*Hist.* iv. 6) that in his early youth he devoted his great abilities to the highest pursuits, and made it his object to enter on public life with a spirit thoroughly fortified against all contingencies. It was natural that such a man should be a warm adherent of the Stoic school of philosophy. His father-in-law, Thrasea Pætus, had been the same, he had been driven to suicide in Nero's reign, and his first words to Helvidius were—"Young man, you have been born into times in which it is well to brace the spirit with examples of courage" (Tacitus, *Annals*, vi. 35). Although he repeatedly offended the emperor, he held several high offices. During Nero's reign he was governor in the province of Achaia, he was also sent into Achaia in command of a legion, and by his good sense and moderation he succeeded in restoring peace and order in that country. By the provocation he was respected and trusted. His well-known sympathies with such men as Diogenes and Cato occasioned his banishment in 66 A.D., and he lived with his wife Fannia in Macedonia until Nero's death. Having been recalled to Rome by Gallus in 68 A.D., he at once impeached Eprius Marcellus, one of the most villainous of the informers, and the very man who had been the accuser of Thrasea Pætus. After an angry debate he dropped the charge, as the condemnation of Marcellus would have involved a host of senators in like ruin. As praetor elect he had once the courage to oppose Vitellius in the senate, and again as praetor in the following year he ventured to sign against the financial policy of Vespasian. Such matters, he maintained, ought to be left to the discretion of the senate. He proposed that the Capitol, which had been destroyed in the Roman conflagration, should be restored at the public cost. It would seem that he rather perversely went out of his way to insult Vespasian, saluting him by his private name, and not recognizing him as emperor in the edicts he had to publish as praetor. There was very possibly in all this some of the affection which often characterized the Stoics. The end of it was that he was banished, his wife Fannia, whose constancy and virtue as a highly commended by his friend the younger Pliny, went with him into exile. Shortly afterwards he was executed by Vespasian's order. His life was written at his widow's request by Helianthus Seneca, it took the form of a warm panegyric, and proved fatal to its author in the reign of Domitian.

HELVOETSLOUY'S (in Dutch, *Helvoetsluis*), a fortified town of the Netherlands, in the province of South Holland, situated in the south of the island of Voornse and-Putten, on the shore of the IJsainghet. It possesses a good harbour, a dry and a wet dock, extensive wharves, and a naval arsenal, and among its more important public buildings are the communal chambers, the Reformed church, dating from 1661-1684, the Roman Catholic church, the synagogue, and the naval college. The population was only 1208 in 1795, by 1840 it had increased to 2533, and by 1874 it was 4135.

Helvoetsluis was founded in the 17th century. The construction of the dock was decreed by the States of Holland in 1618, and the erection of the fortifications in 1638, but it was not till 1690 that the works were completed. The new harbour soon became an important rendezvous for the Dutch fleet, and in 1688 it was the landing point of William of Orange's expedition to England.

HELLOT, PIERRE (1660-1716), monastic historian, was born at Paris in January 1660, of supposed English descent. After spending his youth in study, he entered in his twenty-fourth year the convent of the third order of St Francis, founded at Picpus, near Paris, by his uncle Jérôme Heliot, canon of St Sepulchre. There he took the name of Pius Hippolyte. Two journeys to Rome on monastic business afforded him the opportunity of travelling over most of Italy, and after his final return he saw much of France, while acting as secretary to various provincial heads of his order there. Both in Italy and France he was engaged in collecting materials for his great work, which occupied him about twenty-five years, *L'Histoire des Ordres Monastiques, Religieux, et Militaires, et des Congrégations Séculières, de l'un et de l'autre Sexe, qui ont été établies jusqu'à présent*, published in 8 volumes in 1714-21. Heliot died on January 5, 1716, before the fifth volume appeared, but his friend Maximilien Bullot completed the edition. This work, appearing at first anonymously, has been republished several times, and translated into German. Heliot's only other noteworthy work is *Le Chrétien Moderne* (1695).

HELMANS, EMILIE DOROTHÉE (1798-1885), was born in Duke Street, Liverpool, September 25, 1799. Her father, George Browne, of Irish extraction, was at the time of her birth a merchant in Liverpool, and her mother, whose maiden name was Wagner, was the daughter of the Austrian and Tuscan consul at Liverpool, and of united German and Italian descent. Felicia, the fifth of seven children, was scarcely seven years old when her father failed in business, and retired with his family to Gwyloch, near Abergele, and there the young poetess and her lovely and sisters grew up in the wildest seclusion, in a romantic old house by the sea-shore, and in the very midst of the mountains and myths of Wales, the monotony of her young life being varied only by two visits to London, which she never repeated in after years. The little Felicia was a lovely, precocious child. Her education was desultory, and she may indeed be said to have educated herself, the only subjects in which she ever received regular instruction having been French, English grammar, and the rudiments of Latin. Books of chronicle and romance, and every kind of poetry, she read with avidity, and she studied Italian, Spanish, Portuguese, and German sufficiently to be able to read them with ease and enjoyment. She was also fond of music, and played on the harp and piano, her preference being for simple national and pathetic melodies, especially those of Wales and Spain. In 1808, when she was only fourteen, a quarto volume of her *Juvenile Poems* was published by misapprehension. Among the earliest of these were "Conjugal Lines on her Mother's Birthday," "A Prayer on an Address to the Deity," and some "Lines to Shakespeare,"—stiff, little, childish productions, which show, however, a good ear for rhythm and a considerable imitative faculty. The verses having been rather harshly

criticized in the *Monthly Review*, the little poems were for some days in vogue, but the muse was soon reawakened. One of her brothers was fighting in Spain under Sir John Moore, and Felicia, fired with military enthusiasm, wrote *England and Spain*, or *Valour and Patriotism*, a poem of some length and much elaboration, which was afterwards published and translated into Spanish. Her second volume, entitled *The Domestic Affections and other Poems*, appeared in 1812, on the eve of her marriage to Captain Hemans, which took place in the summer of that year. She lived for some time at Darenty, where her husband was appointed adjutant of the Northamptonshire militia, but about this time his father went on some commercial enterprise to Quebec and died there, and, after the birth of his eldest son, she and her husband took up their abode with her widowed mother at Bronwylla. Here during the next six years four more children—all boys—were born, but in spite of domestic cares and uncertain health she still read and wrote indefatigably. Her poem entitled *The Restoration of Works of Art to Italy* was published in 1816, her *Modes in Greece* in 1817, and in the following year appeared her volume of *Translations from Camoens and other Poets*.

In 1818 Captain Hemans went to Rome, leaving his wife, shortly before the birth of their fifth child, with her mother at Bronwylla. No further explanation than that it was in the first instance for Captain Hemans's health has ever been offered of this step, but it seems to have been then merely a tacit agreement, perhaps on account of their limited means, that they should live for a time apart. Letters were interchanged, and Captain Hemans was often consulted about his children, but the husband and wife remained separate, and indeed never met again. Kind and influential friends—among them the bishop of St Asaph and Bishop Heber—clustered round the poetess and her children. Her health, however, began to fail her, and her beauty, which was of a peculiarly delicate type, is said to have faded rapidly, leaving behind it an habitually worn and harassed expression. She became subject, too, to paroxysms of beating of the heart. Yet for the next six years her literary industry never flagged. In 1819 she published *Tales and Histories in Scenes in Verse*, and in the same year she gained a prize of £50 offered for the best poem on *The Meeting of Wallace and Bruce on the Banks of the Carron*. The poem was published in *Blackwood's Magazine*. In 1820 appeared *The Sceptic and Scurvies to the Memory of the late King*. In June 1821 she won the prize awarded by the Royal Society of Literature for the best poem on the subject of *Dartmoor*, and during the same year she began her play, *The Vespers of Palermo*. She now applied herself to a course of German reading. Kotzebue was her favourite German poet, and her lines on the grave of Kotzebue were one of the first English tributes to the genius of the young soldier poet. *The Voice of Spring*, one of her best known lyrics, was written in 1823, the same year in which she began to contribute to the *New Monthly Magazine*, and in the summer of 1823 a volume of her poems was published by Murray, containing "The Siege of Valencia," "The Last Constantine," and "Behemoth's Feast," which last had appeared previously in a collection edited for a charitable purpose by Joanna Baillie. *The Vespers of Palermo* was acted at Covent Garden, December 12, 1823, and Miss Hemans received £200 for the copyright, but, though the leading parts were taken by Young and Charles Kemble, the play was a failure, and was withdrawn after the first performance. It was acted again in Edinburgh in the following April with greater success, when an epilogue, written for it by Sir Walter Scott at Joanna Baillie's request, was spoken by Miss Henry Siddons. An interchange of notes on this subject was the beginning of a cordial friendship between Mrs Hemans and the novelist. In the same year she wrote *De Chastillon, or the Crusaders*.

but the manuscript was mysteriously lost, and the poem was not published till two years after her death, and then from a rough copy. In 1824 she began "The Forest Sanctuary," which appeared a year later with the "Lays of Many Lands" and miscellaneous pieces collected from the *New Monthly Magazine* and other periodicals.

In the spring of 1825 Miss Hemans, with her mother and children and an unmarried sister, removed from Bronwylla, which had been purchased by her mother, to Rhyllyn, another house belonging to him on an opposite height across the river Clwyd. The contrast between the two houses suggested her *Dramas*. *Scene between Bronwylla and Rhyllyn*. The house itself was bare and unpicturesque, but the beauty of its surroundings has been celebrated in "The Hour of Romance," "To the River Clwyd in North Wales," "Our Lady's Well," and "To a Distant Scene." This time seems to have been the most tranquil in Miss Hemans's life. Her children were growing up about her, her own valuable health was at its best, her popularity was spreading, not only in England but in America, where Professor Norton of Harvard university undertook to superintend the publication of a complete edition of her works and to secure to her the profits. But the death of her mother in January 1827 was a second great looking-point in her life. Her own health began to decline, and though the nature of her illness, which afterwards proved heart complaint, was not at first apparent, she was from this time an acknowledged invalid. In the summer of 1828 the *Records of Woman* was published by Blackwood, and in the same year the home in Wales was finally broken up by the marriage of Miss Hemans's sister and the departure of her two elder boys to their father in Rome. Miss Hemans therefore left Rhyllyn, and took a very small house in the village of Wavertree, near Liverpool, where she hoped to obtain good schooling for her children and society for herself. But, although she had a few intimate friends there, among them her two subsequent biographers, Henry F. Chorley and Mrs Lawrence of Wavertree Hall,—she was disappointed in her new home. She thought the people of Liverpool stupid and provincial, and they, on the other hand, found her uncommunicative and eccentric. In the following summer she travelled by sea to Scotland with two of her boys, to visit the Hamiltons of Chishwood. This visit to Scotland was one of the most daring feats, and perhaps the richest episode, in her uneventful life. She was cordially welcomed in Edinburgh, dined with Jeffrey and other celebrities, visited Henry Mackenzie, heard Alison preach, and stayed with Su David and Lady Wedderburn, and with Sir Robert Liston at Milburn, where she sat for a bust to Angus Fletcher. Above all, while she was at Chishwood, she enjoyed "constant, almost daily, intercourse" with Sir Walter Scott, with whom she and her boys afterwards stayed some time at Abbotsford. "There are some whom we meet, and should like ever after to claim as kith and kin, and you are one of those," was Scott's compliment to her at parting. One of the results of her Edinburgh visit was an article, full of praise, judiciously tempered with criticism, by Jeffrey himself for the *Edinburgh Review*. The poetess returned to Wavertree to compose her *Songs of the Affections*, which was published early in 1830. In the following June, however, she again left home, this time to visit Wordsworth and the Lake country, and in August she paid a second visit to Scotland. She was resolved to leave Wavertree, and wished to make Edinburgh her home, but the climate was pronounced too rigorous, and, as a brother and his family were already settled in Ireland, it was arranged that she should go to live in Dublin. In her new home kind friends and admirers gathered round the invalid, who now had with her only the youngest of her children. She was obliged

to his constantly, and the exertion of writing began to be painful to her. Her poetry of this date is chiefly religious. Early in 1834 her *Hymns for Childhood*, which had appeared some years before in America, were published in Dublin. At the same time appeared her collection of *National Lyrics*, and shortly afterwards *Stanzas and Hymns of Life*. She was planning also a series of German studies, to consist of translations from German authors, with introductions and explanatory notes, one of which, on Goethe's *Tasso*, was completed and published in the *New Monthly Magazine* for January 1834. In intervals of acute suffering she wrote the lyric *Dependency and Deposition*, and dictated a series of sonnets called *Thoughts during Sickness*, the last of which, "Recovery," was written when she fancied she was getting well. After three months spent at Redesdale, Archbishop Whately's country seat, which had been placed at the disposal of the dying poetess, she was again brought into Dublin, where she lingered till spring. The use of her limbs was entirely gone, but her passion for reading remained to the last, and the table at her bedside was strewn with books, one of which always lay open. Her last poem, the *Sabbath Sonnet*, was dictated to her brother on Sunday April 26th, and she died on the evening of Saturday, May 16, 1836, at the age of forty-one. She was buried in a vault under St Anne's church, Dublin. Besides the bust of Miss Hemans by Thomas F. Boucher, there were three portraits taken of her in 1827 by the American painter Vest, one of which has been engraved, and another portrait, an engraving of which is in Chorley's *Memorials*, was painted in 1831 by a young Irish artist, Edward Robinson.

Miss Hemans's poetry is the production of a fine imaginative and enthusiastic temperament, but not of a commanding intellect or very complex or subtle nature. It is the outcome of a beautiful but angularly circumscribed life, a life spent in romantic seclusion, without much worldly experience, and warped and saddened by domestic unhappiness and real physical suffering. Feelings from these circumstances, aided by a course of self instruction at best doubtful and unguided, the emotional in a sensitive and intensely feminine nature was unduly cultivated, and this undue preponderance of the emotional is a prevailing characteristic in Miss Hemans's poetry, and one to which Scott alluded when he complained that it was "too poetical," that it contained "too many flowers" and "too little fruit." Her genius—beautiful and pleasing as it was—was not of a very high order. Like her favourite music, it lay within a small compass, and gave little opportunity for intricate harmonies. Thus her tragedies, and her longer and more complicated poems, such as *The Sceptic* and *Forest Sanctuary*, though by no means devoid of striking passages, are the least notable of her works. It is not, however, as the writer of these more ambitious productions, which in her case at times were but doubtful successes and are now rarely read, but as the author of many short occasional pieces, and especially as a lyricist, that Felicia Hemans has earned so high a place among our poets. In her lyrics she could concentrate her strength on the perfect expression of simple themes. Her skill in versification, her delicate ear for rhythm, and the few ruling sentiments of her native heath found ample scope. In her lyrics Miss Hemans is uniformly graceful, tender, delicately refined,—sometimes perhaps, even here, too fervent, too emotional,—but always pure and spiritual in tone, and in these too she occasionally displays those rare qualities which belong only to the finest lyric genius. Many of her poems, such as "The Treasure of the Deep," "The Better Land," "The Homes of England," "Cassibanus," "The Palm Tree," "The Graves of a Household," "The Wreck," "The Dying Improvisatore," and "The Lost Plaid," have become standard English lyrics, and on the

strength of these, and others such as these, Felicia Hemans is ranked among our chief British lyrical poets.

An edition of Miss Hemans's *Poetical Works* was published, 2 vols., in 1832, *Poetical Remains*, with Memoir by Deity, 1836, *Almanachs*, &c., by H. P. Chonley, 1836, *Recollections of Miss Hemans*, by Miss Lawrence, 1836, *Works of Miss Hemans, with a Memoir of her Life*, by her sister Miss Hastings, 7 vols., 1839, and American reprint, 2 vols., 1817, *Early Blessings*, a Collection of Poems written between eight and fifteen years of age, with a Life of the Authoress, 1840, *Poems*, chronologically arranged, Edin., 1849, *Poems*, copyright edition, Edin. and London, 1873, *Poetical Works*, with a full and complete memoir by W. M. Rossetti, London and Edin., 1874. (F M.)

HEMEL HEMPSTEAD, a market-town of England, county of Hertford, is pleasantly situated on the declivity of a hill near the river Gade, 23 miles N.W. of London, 1½ miles from the Botmoo station of the London and North Western Railway, and on a branch line of the Midland Railway. The town consists almost wholly of one main street about a mile in length. Among the principal buildings are the parish church, cruciform in shape, and partly Norman in style, surmounted by a lofty octagonal spire, and containing an old base of the time of Edward III.; the town-hall, a long narrow building formerly supported on square wooden pillars, but whose open market place underneath has now been converted into a corn exchange, the union workhouse, and the West Herts infirmary. The chief industry is straw plaiting, but there are also manufactories of paper, an iron foundry, breweries, and tanneries. The population of the township in 1871 was 5996, and of the parish 8720.

From its name, meaning high stead or place, the town is apparently of Saxon origin. In Domesday it is written *Hemstede* and *Hemstedes*. It received a charter of incorporation from Henry VIII., which was renewed by Cromwell. It still makes annual choice of a bailiff, but he possesses no magisterial authority.

HEMEROBAPTISTS, an ancient Jewish sect, so named from their observing a practice of daily ablution as an essential part of religion. Epiphanius, who mentions their doctrine as the fourth heresy among the Jews, classes the Hemero baptists doctrinally with the Pharisees, from whom they differed only in, like the Sadducees, denying the resurrection of the dead. The name has been sometimes given to the Mendicans on account of their frequent ablutions, and in the *Clementine Homilies* (ii. 23) St John the Baptist is spoken of as a Hemero baptist. Mention of the sect is made by Hegesippus (see Euseb., *Hist. Eccl.*, iv. 22) and by Justin Martyr in the *Dialogue with Trypho* (xv.).

HEMINGFORD, or **HÄMMINGFORD**, **WALFORD**, a Latin chronicle of the 14th century, was a canon regular of the Austin Priory of Gisborough, now Gisbrough, in Yorkshire. Leland calls him Hemingoburgus, and in one of the manuscripts of his chronicle his name appears as Hemingburg. In a document of the priory his name is also given as De Hemingburgh, and in Gisbrough Chantryal mention is made of a neighbouring family of that name. Bale seems to have been the first to give him the name by which he is more commonly known. His chronicle embraces the period of English history from the Conquest (1066) to the nineteenth year of Edward III., with the exception of the latter years of Edward II. It ends with the title of a chapter in which it was proposed to describe the battle of Crécy (1346), but the chronicle seems to have died before the required information reached him. In compiling the first part, Hemingford apparently used the histories of Eadmo, Hoveden, Henry of Huntingdon, and William of Newbury, but the reigns of the three Edwards are original, composed from personal observation and information. There are several manuscripts of the history extant,—the best perhaps being that presented to the College of Arms by the earl of Arundel. The work is correct and judicious, and written in a pleasing style. One of its special features is the preservation in its pages of copies of

many-rayed umbels of small white flowers, the general involucre consisting of several, the partial ones of about three short lanceolate bracts, the latter being usually turned towards the outside of the umbel. The flowers are succeeded by broadly ovate fruits, the mericarps (half-fruits) having five ribs which, when mature, are waved or cinate, there are no vitæ or oil cysts, and when cut across the albumen is seen to be deeply furrowed on the inner face, so as to exhibit in section a uniform outline. The fruits when triturated with a solution of caustic potash evolve a most unpleasant odour.

Hemlock is a violent poison, but it varies much in potency according to the conditions under which it has grown, and the season or stage of growth at which it is gathered. In the first year the leaves have little power, not in the second are their properties developed until the flowering period, at which time, or later on when the fruits are fully grown, the plant should be gathered. The wild plant growing in exposed situations is to be preferred to garden grown samples, and is more potent in dry warm summer than in those which are dull and moist.

The poisonous property of hemlock resides chiefly in the alkaloid *coniine* or *conine* which is found in both the fruits and the leaves, though in exceedingly small proportions in the latter. Conine resembles nicotine in its deleterious action, but is much less powerful. No chemical action has been observed. The plant also yields several less poisonous crystallizable bases called *conhydrins*, which may be converted into conine by the abstraction of the elements of water.

When collected for medicinal purposes, for which both leaves and fruits are used, the former should be gathered at the time the plant is in full blossom, while the latter are said to possess the greatest degree of energy just before they ripen. The fruits are the chief source whence conine is prepared. The principal forms in which hemlock is employed are the extract and juice of hemlock, hemlock powder, and the tincture of hemlock fruits. Large doses produce vertigo, nausea, and paralysis, but in smaller quantities, administered by skillful hands, it has a sedative action on the nerve. It has also some reputation as an anæsthetic and is-olvent, and as an anodyne.

The acid narcotic properties of the plant render it of some importance that one should be able to identify it, the more so as some of the compound leaved umbellifers, which have a general similarity of appearance to it, form wholesome food for man and animals. Not only is this knowledge desirable to prevent the poisonous plant being detrimentally used in place of the wholesome one, it is equally important in the opposite case, namely, to prevent the most being substituted for the remedial agent. The plant with which hemlock is most likely to be confounded is the *Lathyrus sylvester*, or cow-parsley, the leaves of which are freely eaten by cattle and rabbits, thus plant, like the hemlock, has spotted stems but they are hairy, not hairless, it has much-divided leaves of the same general form, but they are downy and aromatic, not smooth and nauseous when bruised, the fruit of the *Lathyrus*, besides, is linear-oblong and not ovate.

HEMP, *Cannabis sativa*, an annual herb, having angular 10 rib stems and alternate lobed leaves. The bast fibres of *Cannabis* are the hemp of commerce, but under the name of hemp fibrous products from many different plants are often included. Sunn hemp is the best fibre of a papilionaceous plant, *Orobanche javanica*, of India and the Banda Islands, *Urtica cannabina*, an Indian malvaceous plant, yields blown or Bombay hemp. Jute or Pant hemp is produced by *Cochlosoma capillaris*, and *C. olata* var., and to some extent by *C. fusca*, *C. fusciculata*, and *C. decem-angulata*. Manila hemp or feather fibre is derived from

the fibro-vascular bundles of certain monocotyledonous, namely, several species of *Musa*, chiefly from *M. textilis*, but to some extent from *M. sapientum*, *M. ensata*, *M. mundana*, and *M. Cavendishii*, in India, New Guinea, the Philippines, &c. Pita hemp is produced from certain species of *Lagotis*, the *Alse odinata* of Central America yields grass-hemp, and *Muruva* or bowstring-hemp is obtained from an aloe-like plant, *Sarcocolla regina*, in Bengal, Ceylon, Java, and southern China.

The hemp plant, like the hop, which is the other member of the same natural order, *Cannabaceæ*, is dioecious, that is, the male and female flowers are borne on separate plants. The male plant is smaller than the female, and ripens and dies earlier in the summer. The foliage of the female plant is darker and more luxuriant than that of the male. The leaves of hemp are constituted of 5 to 7 leaflets, the form of which is lanceolate acuminate, and sharply cinate. The loose panicles of male flowers and the short spikes of female flowers arise from the axils of the upper leaves. The height of the plant varies greatly with season, soil, and manuring, a variety (*C. sativa*, var. *gigantea*) has produced specimens over 17 feet in height, but the average height of the common sort is about 8 to 10 feet. There is but one species of hemp known, *Cannabis sativa*, the *C. indica*, Lam., and *C. chinensis*, Delile, owing their differences to climate, and losing many of their peculiarities when cultivated in temperate regions. Rumphius (in the 17th century) had noticed these differences between Indian and European hemp.

The original country of the hemp-plant was doubtless in some part of temperate Asia, probably near the Caspian Sea. It spread westward throughout Europe, and southward through the Indian peninsula.¹

Wild hemp still grows on the banks of the Lower Volga and the Volga, near the Caspian Sea. It extends to Persia, the Altai range, and northern and western China. It is found in Kashmir, and on the Himalayan, growing vigorously as far up as 6000 or even 10,000 feet.

Hemp is grown for three products—(1) the fibre of its stem, (2) the resinous secretion which is developed in hot countries upon its leaves and flowering heads, (3) its oily seeds.

Hemp has been employed for its fibre from ancient times. Herodotus (iv 74) mentions the wild and cultivated hemp of Scythia, and describes the hempen garments made by the Thracians as equal to linen in fineness. Herodotus says the Thracian women made sheets of hemp. Mosehon (about 200 n c) records the use of hempen ropes for rigging the ship "Byzantium" built for Hiero II. The hemp plant has been cultivated in northern India from a considerable antiquity, not only as a drug but for the fibre. The Anglo-Saxons were well acquainted with the mode of preparing hemp. Hempen cloth became common in central and southern Europe in the 13th century.

The medicinal and intoxicating properties of hemp have probably been known in Oriental countries from a very early period. An ancient Chinese herbal, part of which was written about the 5th century n c, while the remainder is of still earlier date, notices the seed and flower bearing kinds of hemp. Other early writers refer to hemp as a

¹ The names given to the plant and to its products in different countries are of interest in connection with the distribution of the fibre and resin. In Sanskrit it is called *gani*, *ganja*, *shamaja*, *bangs*, and *ganjala*, in Bengali, *ganja*, Persian, *bang* and *canna*, Arabic, *kannab* or *cannab*, Greek, *jannabula*, Latin, *cannabula*, Italian, *cannapa*, French, *chanvre*, Spanish, *cañamo*, Portuguese, *canabim*, Russian, *kannop*, Lithuanian and Lithuanian, *kannopas*, Slavonic, *kanopa*, *kanab* and *kanab*, Anglo-Saxon, *hemp*, Dutch, *hennep*, German, *hanf*, English, *hemp*, Danish and Norwegian, *hemp*, Icelandic, *hempur*, and in Swedish, *hemp*. The English word *cannas* sufficiently reveals its derivation from *cannabula*.

remedy. The medicinal and dietetic use of hemp spread through India, Persia, and Arabia in the early Middle Age. The use of hemp (liang) in India was noticed by Girardin d'Orville in 1668. Barlet in his *Treasury of Drugs* (1690) describes it as of "an infatigable quality and poisonous use." Attention was recalled to this drug, in consequence of Napoleon's Egyptian expedition, by De Saey (1809) and Rouger (1810). Its modern medicinal use is chiefly due to trials by Dr. O'Shaughnessy in Calcutta (1838-1842). The plant is grown partly and often mainly for the sake of its resin in Persia, northern India, and Arabia, in many parts of Africa, and in Brazil.

The hemp plant grows in some parts of the United States yields the active resin so freely that less than 1 grain of the extract is a full dose. But it is as a fibre-producer that the hemp is now being more extensively cultivated in the United States. Hemp seeds were ordered for Plymouth soil as early as 1639, but the greater profit derivable from tobacco has always opposed the development of hemp-growing. The plant is chiefly grown in the States of Kentucky, Missouri, Tennessee, Ohio, Indiana, and New York. The produce of Kentucky in 1877 was 6110 tons. According to the census of 1870 the total production of the United States was 12,740 tons. In the northern part of the State of New York the crop is valued chiefly for the seeds, which may be from 20 to 40 bushels or more per acre. The produce per acre in the United States is from 700 to 1000 lb of fibre, 4 to 6 pecks of seed being usually sown.

Although the hemp plant is grown in India chiefly for the production of its narcotic or intoxicating resin, yet a good deal of the hemp fibre is produced there. It is imported into England, however, chiefly from Russia, the United States, Italy, Holland, Germany, Hungary, and Turkey. It is grown in Ireland, and in some parts (Suffolk and Lincolnshire) of England. It thrives well in Algeria. It requires a rich deep soil and heavy manuring, and is an exhausting crop. In Great Britain about 6 pecks of seed per acre are sowed, 18 inches apart, in the middle of April. The male plants are pulled from the end of July to the end of August, the female or seed-bearing plants being gathered in September.

The British reports of hemp cannot be sustained with accuracy, as the official returns include under that name, the fibres of many hemp substitutes. The following statement of hemp imported into the United Kingdom must therefore be taken with all necessary reserve—

1873	1,247,354 cwts	1876	1,174,859 cwts
1874	1,210,108 "	1877	1,254,667 "
1875	1,850,768 "	1878	1,229,689 "

The following table gives the sources whence the supplies were chiefly drawn in the year 1877. But it may be again observed that the figures given for the imports from India, the Philippines, and other places to a less degree, include Manila hemp, Sunn hemp, and other spurious hems.

Imports of Hemp into the United Kingdom in 1877

From	Dressed	Rough	For in Cordage
	Cwts	Cwts	Cwts
Russia	4,679	347,038	18,826
Germany	7,088	189,741	20,889
Italy	10,477	151,632	44,802
Philippines		332,311	
United States		10,728	
Mexico		33,199	
India		62,827	
Other countries	6,857	18,988	4,668

There were sent out 11,780 cwt of dressed English grown hemp, more than half of this going to France. 1,167 cwt of foreign and colonial dressed hemp were exported to British America and other countries, with 139,510 cwt of rough hemp, and 137 cwt of cordage.

Newly all the hemp imported into the United Kingdom is landed at Liverpool, London, Hull, and Leam. Most of it is employed in the manufacture of cables, ropes, cordage, twine, seaming, tar

papers, canvas, and sailcloth. The finest hemp comes from Italy, but it is almost equaled by the highest qualities of the Russian hemp. Russian hemp varies much in price, according to quality and market fluctuations, its price in November 1879 was from £20 to £25 per ton. It is a golden hemp (fitching from £38 to £41).

In order to free the fibre of the hemp plant from the soft and such as pectinaceous matter and the tissues of the bark, the stems are submitted to nearly the same processes as those described in the article Flax. They are dried, beaten, or crushed in a hemp mill, and furnished of *rotel*, judiciously in soft water, after which they are again beaten with wooden mallets, or in a specially constructed machine called a *beater*. After beating the stems are washed, and thus the separation of the fibres facilitated by the rubbing and striking to which they are subjected. The fibres are then *bad* or *combed*.

According to Vétillat, the average length of Tunisian hemp fibres is 80 inch, the extremes being 3 and 21 inches. Di Milla gives 0005 to 0007 inch as the diameter of fibres, the actual average being 0001 inch in breadth. Under the microscope hemp fibres resemble those of flax, both being best fibres, and differ widely from those of Manila hemp or New Zealand flax, they are longitudinally striated cylinders, sometimes free and sometimes attached in small bundles. A hemp coil of 1 square millimetre section will be, according to Habicht, an average weight of 94.5 kilogrammes without the skin—sometimes as much as 60 kilos.

The chief constituent of the fibre of hemp is of course cellulose, but small quantities of other substances are also present—the most important being, however, being rubber in cellulose. A fine sample of Italian hemp gave on analysis the following percentages—water 8.9, wax 0.6, ash 0.8, matters soluble in water 3.6, lignine, albumenoids, &c. 1.4, cellulose 77.3. An ordinary sample of flax in water contained no less than 10.6 per cent of moisture, and 4.7 of mineral matter, with but 72 of pure cellulose. By boiling a portion of this sample for four hours with water in a sealed tube at 170° C., a soluble extract amounting to 2.6th of the original weight was obtained. A sample of hemp giving 1.5 per cent of moisture, and 5 of mineral matter, with but 72 of pure cellulose. Dilute solutions of iodine and sulphuric acid, successively applied, gave to hemp fibres a greenish hue. The ash of hemp is rich in lime.

Hemp resin—Hemp as a drug or intoxicant for smoking and chewing occurs in the three forms of liang, ganja, and charas.

(1) *Bhang*, the Hindustani *sudha* or *subi*, consists of the dried leaves and small stalks of the hemp, a few fruits occur in it. It is of a dark brownish green colour, and has a faint peculiar odour and but a slight taste. It is smoked with or without tobacco, or it is made into a sweetmeat with honey, sugar, and aromatic spices, or it is powdered and infused in cold water, yielding a turbid drink, *sudha* *liachish* is one of the Arabic names given to the Syrian and Turkish preparations of the resinous hemp leaves. One of the commonest of these preparations is made by heating the liang with water and butter, the butter becoming thus changed with the resinous and active substances of the plant.

(2) *Ganja*, the guara of the London brokers, consists of the flowering and fruiting heads of the female plant. It is brownish green, and often resembles liang, as in colour and taste. Some of the more esteemed kinds of hashish are prepared from this ganja. Ganja is met with in the Indian bazaars in dense bundles of 24 plants or heads apiece. The hashish in such extensive use in Central Asia is often seen in the bazars of large cities in the form of cakes, 1 to 3 inches thick, 5 to 10 inches broad, and 10 to 15 inches long.

(3) *Chasus*, or *churru*, is the resin itself collected, as it exudes naturally from the plant, in different ways. The best sort is gathered by the hand like opium, sometimes the resinous exudation of the plant is made to stick fast of all to cloths, or to the leather garments of men, or even to their skin, and is then removed by scraping, and afterwards consolidated by kneading, pressing, and rolling. It contains about one-fourth its weight of the resin. But the churru prepared by different methods and in different countries differs greatly in appearance and purity. Sometimes it takes the form of egg-like masses of greyish-brown colour, having when of high quality a shining resinous

fracture. Often it occurs in the form of irregular friable lumps, like pieces of impure lined oil-cake.

Hemp, however consumed, acts in a most strange way upon the nervous system, but its effects differ greatly with races as well as with individuals. Generally the first effect of a small dose is to produce increase of appetite and cheerfulness. Larger doses produce hallucinations, delirium, sleep, and sometimes cataplexy. During the dreamy state induced by an average dose of hashish, the patient becomes the sport of rapidly shifting ideas. Excess of perception as to time and place is a conspicuous characteristic of its effects on the mind. For the connexion of the name *hashish* with hashish, see vol. II p. 723.

Extract of hemp has been repeatedly tried in modern European medical practice without very consistent or satisfactory results. It has antispasmodic and anodyne characters, and has been employed in tetanus, spasmodic cough, hydrophobia, and some forms of mania. It is a quietor of the nervous system, but does not cause constipation, check the appetite, nor diminish the secretions like opium.

Hemp is very largely used in Eastern countries as an intoxicant and narcotic—probably by nearly 300 millions of the human race. The amount consumed cannot be estimated. Of the hemp and chlorus there was sent in 1870 not less than 10,000 worth through the Khylai Pass into British India.

There are three substances in the hemp drug to which its activity has been attributed. Of these, the resin, separated and investigated by Messrs T. & H. Smith, is the most abundant and probably the most important, and yet its chemical nature and properties are by no means certain. It is soluble in alcohol, and has a warm, bitter, resinous taste with a slight odor. It melts between 70° and 80° C., and has a pink brown color. It is called *cannabin*. Cannabin is the volatile oil of Indian hemp obtained by distilling hemp in contact with water. Its composition is represented by $C_{11}H_{16}$, it boils between 235° and 240°. Cannabin is accompanied by a crystalline hydrocarbon containing 84 per cent carbon and 16 per cent hydrogen. The supposed occurrence of an active principle in hemp has not been confirmed, and would not in any way suffice to explain the properties of the drug. Moreover, tobacco is often added to hemp. That there is a volatile alkaloid in hemp, though in small quantities, is, however, established beyond doubt. The proportion of this resin in grass was found by Messrs T. & H. Smith to be 8 to 7 per cent. Gassaniell gives 8 per cent, is obtained from the Egyptian hemp. The volatile oil in fresh hemp probably does not exceed 3 parts in 1000. By treating the commercial resinous extract of Indian hemp with strong nitric acid, Boles and Francis obtained (*Journal Chem. Soc.*, vol. IV, p. 417) an oxidation product, soluble in alcohol and crystalline in long flat prisms. The formula $C_{11}H_{16}O_2$ has been assigned to this substance, which is known as oxy-cannabin.

Hemp Seed, Cake, and Oil.—The ripe seeds, really fruits, being nuts or achenes of the hemp plant, contain about 34 per cent of oil and 16 of albuminoids. When the crushed seeds have been submitted to pressure, the residual cake is found to retain about 7 per cent of oil. The value of hemp cake as a cattle-food is lessened by its purgative property. The seeds are much used as a food for singing birds. A hundred pecks of the seed yield from 70 to 75 of cake and 25 to 30 of oil. This oil has drying properties, though it is in this respect much inferior to linseed oil. Its specific gravity is 9307. The seeds are reniform ovate, about $\frac{1}{8}$ inch in length, and of a dark grey colour, with a pale ash-coloured network of surface-markings.

See Bentley and Trimen's *Medicinal Plants*, No. 331, *Villiers's Botanical Atlas*, plate 1, fig. 72-77, *Dalman's Atlas of Plants of India*, *Boyle's Fibrous Plants of India*, *Cultivation of Hemp in India*, Dr O'Shaughnessy's *Preparation of Indian Hemp or Gunjah*, *Yak's Treatise on Antiquaries*, *Engo Miller's Pharmacopoeia*, the *Dispensary of the United States*, *Kalm's Description of Siberia*, Dr G. Meubius's *Studien über den Hanf*, and *Johnson's Chemistry of Common Life*, 1879. (A. H. C.)

HEMS, HOMS, or HYMS, a town of Syria, about 63 miles by road north-east of Tripoli (Taibulus), situated 1313 feet, according to Cernik, above the level of the sea, on the

eastern side of the valley of the Nahr el Ayy or Orontes, which about 4 miles further down forms the lake of Hems, Atun, or Kabas. The *Archeol.* of castle, a great mound "still crowned with a tate of torn and ruined towers," forms a striking landmark well known to the caravans journeying north from Damascus. It is about 120 feet in height, and has a breadth of 135 feet and a width of 375. According to Captain Dutton, it probably occupies the site of the temple of the sun, which formed the glory of the ancient city. Not only does it contain columnar masses of syenite, grey granite, and white marble, but he found, apparently in position, a Doric palæstra. Though the ancient walls of Hems, with a cement of about a mile and a half, are greatly dilapidated and even in many places practically demolished, the town is entered by regular gates, six in number, which in olden times bore the names of the planets. Within it presents little except narrow and tortuous streets, poorly paved and foul, with houses for the most part of the meanest description, but none the less it is the seat of a Turkish vice governor or mutessim, as well as of a Greek and a Maronite bishop, and its cavalry barracks are capable of containing two regiments. As the market-town of the neighbouring tribes it has some commercial importance. It trades in cotton, sesame, and oil, and among its craftsmen it numbers a body of skilful goldsmiths and about 8000 silk weavers, whose looms produce the finest kind of keffiyeh or head cloths. The population is estimated at from 20,000 to 40,000, and about 7000 are Christians. Jews are conspicuous by their absence, though one of the gates of the town in the quarter which they formerly occupied is still called the "Jews' Gate."

Homs is the *Hemus*, *Emysus*, or *Hemysus* of the Romans, and by Ptolemy it is regarded to the district of Apamea. Its inhabitants are mentioned among the early opponents of the Roman emperor Julian in the middle of the 4th century, and in 518 A.D. it was ravaged by Huns, and held office as a part of the sun. It was in the neighbourhood of the town that the army of Zenobia was routed by Aurelian. The first Christian bishop is said to have been St. Simeon. About fifteen years after the Hagan Khalid bin Walid, who was found his grave in one of its suburbs, made him self master of Homs, and from 1068 to 1187 it was in the hands of the crusaders. It was probably Saladin, by whom they were expelled, that turned the temple of the sun, which under Christian rule had been used as a cathedral, into the chief fortress of the place. In July 1831 Ibrahim Pasha, having defeated the governor of Aleppo at Homs, carried the fortress to be blown up.

The spot *Kalab el Akhal* is named in the town, and the people show another grave which they wrongly believe to be that of Jehu el Akhal.

See Bayly and Trivett's *Diary*, *Unexplored Syria*, 1879.

HEMSTERHUIS, FRANKHUIS (1720-1790), writer on æsthetics and moral philosophy, was born at Franeker in Holland in 1720. He received an excellent education from his father, Theobaldus Hemsterhuis, noticed below, and completed his studies at the university of Leyden. There undoubtedly he was attracted towards the study of the Platonic philosophy, which exercised the greatest influence both on the form and on the matter of his own writings. He did not, however, devote himself to a lean life after completing his university course, but entered upon practical affairs, and for many years acted as secretary to the state council of the United Provinces. His interests were mainly philosophical, and partly by direct social intercourse with a few similarly disposed friends, partly by correspondence with philosophical writers of other countries, mainly with Jacobi, he preserved the continuity of his philosophical work. His writings, none of which can be described as of high speculative worth, are distinguished by elegance of form and by the touch of refined sentiment which is not uncommon among the amateur or dilettante philosophers of the 18th century. Any direct contributions to philosophy made by him are in the department of æsthetics or the general analysis of feeling. He died in 1790.

His first work, published in 1769, was a *Lettre sur les Sculpteurs*, written, like all the others, in French. It was followed in 1770 by the *Lettre sur les dactyles*, in 1772 by the *Lettre sur l'homme et ses rapports*, in 1778 by *Sophyie*, a dialogue on the relation between soul and body, in 1779 by *Alceste*, a dialogue on the existence of the Divine Being, in 1787 by *Alceste ou l'ame d'or*, by *Stron*, *ou des facultés du Poëte*, and by the *Lettre de Dactyle à Dactyle* ou *l'Alphabète*. Collected editions of his works have been published in 1792 (2 vols.), and more completely by Meyboom, in 1846-50 (6 vols.). See Guizot, *François Hénault*, in *Revue des Deux Mondes* (Paris, 1866).

HEMSTERHUIS, *Transmut* (1685-1766), philologist and critic, was born on January 9, 1685, at Groningen in Holland. His father, a learned physician, recognizing the abilities of his son, gave him so good an early education that, when he entered the university of his native town in his fifteenth year, he speedily proved himself to be the best student of mathematics. After a year or two at Groningen, he was attracted to the university of Leyden by the fame of Perizonius, and while there he was entrusted with the flattering duty of arranging the manuscripts in the library. Though he accepted an appointment as professor of mathematics and philosophy at Amsterdam in his twentieth year, he had already directed his attention to the study of the ancient languages. In 1706 he completed the edition of Pollux's *Onomasticon* begun by Loderlin, but the praise he received from his countrymen was more than counterbalanced by two letters of criticism from Bentley, which mortified him so keenly that for two months he refused to open a Greek book. In 1717 Hemsterhuis was appointed professor of Greek at Franeker, but he did not enter on his duties there till 1720. In 1738 he became professor of national history also. Two years afterwards he was called to teach the same subjects at Leyden, where he died, April 7, 1766. Hemsterhuis deserves special note for reinstating the study of Greek in its honorable place among his fellow-countrymen, while he was also the founder of a laborious and useful Dutch school of criticism, of which Valartkenae, Lennep, and Ruhnken are the most famous disciples.

His chief writings are the following:—*Luciani Colloquia et Tiron*, 1708; *Antisthenis Plutus*, 1741; *Nota, &c.*, ad *Lexicon solum in Epicharmo in the Mivestiana Critica* of Ammonium, vols. iii and iv; *Observationes ad Chrysostomum Homilias*, *Oratorum*, 1784, a Latin translation of the *Briefs of Antisthenes*, in Kuster's edition, notes to Bynae's *Thomas Magister*, to Albert's *Metaphysica*, to Bynae's *Colloquia*, and to Bynae's *Prologus*. See *Epitome T. Hemsterhuis* (with Bentley's letters) by Ruhnken, 1789, and *Supplementa Annotationes ad Epitome T. Hemsterhuis*, &c., Leyden, 1874.

HÉNAULT, CHARLES JEAN FRANÇOIS (1685-1770), French historian, was born in Paris 8th February 1685. His father, a farmer-general of taxes, was a man of literary tastes, and young Hénault obtained a good education at the Jesuit college and the Collège des Quatre-Nations. Captivated by the eloquence of Massillon, he in his fifteenth year entered the oratory with the view of becoming a preacher, but after two years' residence he changed his intention, and, inheriting a position which secured him access to the most select society of Paris, he at an early period achieved distinction by his gay, witty, and graceful manners, and by his literary talent as manifested in the composition of various light poetical pieces, and of two discourses which respectively gained a prize at the French Academy in 1707, and at the Académie des Jeux Floraux in 1708. In 1706 he became councillor of the parliament of Paris, and in 1710 he was chosen president of the court of *appêls*. He was admitted into the French Academy in 1725, and subsequently into the leading literary societies of Europe. After the death of Bernard de Clugnot he became superintendant of the household of Queen Marie Leszcinska, whose intimate friendship he had previously enjoyed. On his recovery in his fifth year from a dangerous malady, he professed to have undergone religious conversion and retired into private life, devoting

the remainder of his days to study and devotion. His devotion was, however, according to the Marquis d'Argenson "exempt from fanaticism, persecution, bitterness, and intrigue," and it did not prevent him from continuing his friendship with Voltaire, to whom it is said he had formerly rendered the service of saving the manuscript of *La Henriade*, when its author was about to commit it to the flames. The literary work on which Hénault bestowed his chief attention was the *Abégé Chronologique*, first published in 1744 without the author's name. It is a model of its kind, and is valuable both for popular use and as a work of reference. In the compass of two volumes he has compressed the whole history of France from the earliest times to the death of Louis XIV. His information is for the most part drawn from original sources, and for such a work the number of errors committed by Hénault was remarkably small. The results of deep researches and lengthened discussions on public law are summed up in a few words. The moral and political reflexions are always short and generally as fresh and pleasing as they are just. A few masterly strokes reproduce the leading features of each age and the characters of its illustrious men, accurate chronological tables set forth the most interesting events in the history of each sovereign and the names of the great men who flourished during his reign, and interspersed throughout the work are occasional chapters on the social and civil state of the country at the close of each one in its history. Continuations of the work have been made at separate periods by Fantin des Odoards, by Anguis with notes by Walckenaer, and by Michaud. Besides some other historical works of minor importance Hénault wrote several dramatic pieces of no particular merit. He died at Paris, 24th November 1770. His *Mémoires*, published in 1884, are somewhat fragmentary and disconnected, but contain many interesting anecdotes and details regarding persons of note.

See the *Correspondence* of Grimm, of Madame de La Harpe, and of Voltaire, the notes by Walckenaer in the edition of the *Chronologie*, and Sainte-Beuve, *Œuvres de La Harpe*, vol. iii.

HENBANE (in French, *gysperme*, from the Greek *hyoscyamus*, or hog-bean, in Italian, *hyoscyamus*, and in German, *Schwarz der Dilsen*, art, *Hubnettol*, *Sindurke*, and *Zygurne-Korn* or "gypsy's corn") is the common name of the *Hyoscyamus niger*, a Solanaceous plant indigenous to Britain, found wild in waste places, on rubbish about villages and old castles, and cultivated for medical use at Mitcham and other places in Surrey, and in Bedfordshire, Cambridgeshire, and Hereford. It occurs also in central and southern Europe and in western Asia, and has long been naturalized in the United States. There is no form of the plant, an annual and a biennial, which spring indifferently from the same crop of seed,—the one growing on during summer to a height of from 1 to 2 feet, and flowering and perfecting seed, the other producing the first season only a tuft of radical leaves, which disappear in winter, leaving underground a thick fleshy root, from the crown of which arises, in spring a branched flowering stem, usually much taller and more vigorous than the flowering stems of the annual plants. The biennial form is that which is considered official. The radical leaves of this biennial plant spread out flat on all sides from the crown of the root, they are ovate oblong, acute, stalked, and more or less irregularly-toothed, of a greyish green colour, and covered with viscid hairs, these leaves perish at the approach of winter. The flowering stem pushes up from the root-crown in spring, ultimately reaching from 3 to 4 feet in height, and as it grows becoming branched, and furnished with alternate sessile leaves, which are stem clamping, oblong, unequally-lobed, clothed with glandular clammy hairs, and of a dull grey-green, the whole plant having a powerful nauseous

odoni. The flowers are shortly stalked, the lower ones growing in the fork of the branches, the upper ones sessile in one-sided leafy spikes which are rolled back at the top before flowering, the leaves becoming smaller upwards and taking the place of bracts. The flowers have an unequal calyx, which persists almost the fruit and is strongly veined, with five stiff, broad, almost prickly lobes, these, when the soft matter is removed by maceration, form very elegant specimens when associated with leaves prepared in a similar way. The corolla is obliquely funnel shaped, of a dirty yellow or buff, marked with a close reticulation of purple veins. The capsule opens transversely by a convex lid, and contains numerous seeds. Both the leaves and the seeds are employed in pharmacy. The Mahomedan doctors of India are accustomed to prescribe the seeds of *Henbane* yields a poisonous alkaloid, *hyoscyamine*, which is stated to have properties almost identical with those of atropine, from which it differs in being more soluble in water. It is usually obtained in an amorphous, scarcely over in a crystalline state. Its properties have been investigated in Germany by Husemann, Schiörf, Hölzel, and Hölzel finds its chemical composition expressed by $C_{17}H_{23}NO_3$. (Compare Hellmann, *Beitrag zur Kenntnis der physiologischen Wirkung des Hyoscyamins*, &c., Jena, 1871.)

In small and repeated doses *henbane* has been found to have a narcotising effect upon persons affected by severe nervous irritability. In poisonous doses it causes loss of speech, distortion, and paralysis. In the form of extract or tincture it is a valuable remedy in the hands of a medical man, either as an anodyne, a hypnotic, or a sedative. The extract of *henbane* is rich in nitrate of potassium and other inorganic salts. The smoking of the seeds and capsules of *henbane* is noted in books as a somewhat diabolical remedy adopted by country people for toothache. Accidental poisoning from *henbane* occasionally occurs, owing sometimes to the apparent edibility and wholesomeness of the root.

HENDERSON, ALEXANDER (1583–1646), a celebrated Scottish ecclesiastic, was born in 1583. He was educated at the university of St Andrews, where he was appointed professor of rhetoric and philosophy and quoadvisor of the faculty of arts in 1610. A year or two after this he was presented to the living of Louchers by Archbishop Gladstanes. As Henderson was forced upon his parish by an archbishop, and as he was known to sympathize with Episcopacy, his settlement was at first extremely unpopular, but he subsequently changed his views, and became a Presbyterian in doctrine and church government, and one of the most esteemed ministers in Scotland. He early made his mark as a church leader, and took an active part in petitioning against Episcopal innovations. On the 1st of March 1638 the public signing of the "National Covenant" began in Greyfriars Church, Edinburgh. Henderson is mainly responsible for this document, and he seems always to have been applied to when any manifest of unusual ability was required. In July of the same year he proceeded to the north, to debate on the "Covenant" with the famous Aberdeen doctors, but he was not well received by them. "The voyd church was made fast, and the keys kepted by the magistrats," says Baillie. Henderson's next public appearance was in the famous Assembly which met in Glasgow on the 21st of November 1638. He was chosen moderator by acclamation, but, as Baillie says, "incomparable the ablest man of us all for all things." The marquis of Hamilton was the king's commissioner, and when the Assembly met on Monday morning with the trial of the bishops, he formally dissolved the meeting under pain of treason. Nothing daunted, however, they sat till the 30th of December, deposed all the Scottish bishops, excommunicated a number of them, repealed all acts

favouring Episcopacy, and reconstituted the Scottish Kirk on thorough Presbyterian principles. During the sitting of this Assembly it was carried by a majority of seventy-five votes that Henderson should be transferred to Edinburgh. He had been at Louchers for about twenty-three years, and was extremely reluctant to leave it. While Scotland and England were preparing for the "First Bishops' War," Henderson drew up two papers, entitled respectively—*The Remonstrance of the Nobility, and Instructions for Defensive Arms*. The first of these documents he published himself, the second was published against his wish by Corbet, a deposed minister. The "First Bishops' War" did not last long. At the Pacification of Berks the king had virtually granted all the demands of the Scots. In the negotiations for peace Henderson was one of the Scottish commissioners, and made a very favourable impression on the king. In 1640 Henderson was elected by the town council of Edinburgh university—an office to which he was annually re-elected till his death. The Pacification of Berks had been wrong from the king, and the Scots, seeing that he was preparing for the "Second Bishops' War," took the initiative, and pressed into England so vigorously that Charles had again to yield everything. The maturing of the treaty of peace took a considerable time, and Henderson was again active in the negotiations, first at Ripon, and afterwards at London. While he was in London he had a personal interview with the king, with the view of obtaining assistance for Edinburgh university from the money formerly applied to the support of the bishops. On Henderson's return to Edinburgh in July 1641, the Assembly was sitting at St Andrews. To suit the convenience of the parliament, however, it removed to Edinburgh, and Henderson was elected moderator of the Edinburgh meeting. In this Assembly he proposed that "a confession of faith, a catechism, a directory for all the parts of the public worship, and a platform of government, wherein possibly England and we might agree," should be drawn up. This was unanimously approved of, and the laborious undertaking was left in Henderson's hands, but the "notable motion" did not lead to any immediate results. During Charles's second state visit to Scotland, in the autumn of 1641, Henderson acted as his chaplain, and managed to get the funds, formerly belonging to the bishops of Edinburgh, applied to the metropolitan university. In 1642 Henderson was engaged in corresponding with England on ecclesiastical topics, and, shortly afterwards, he went to Oxford to mediate between the king and his parliament, but his mission proved a failure. A memorable meeting of the General Assembly was held in August 1643. Henderson was elected moderator for the third time. He presented a draft of the famous "Solemn League and Covenant," which was received with great enthusiasm. Unlike the "National Covenant" of 1638, which applied to Scotland only, this document was common to the two kingdoms. Henderson, Baillie, Rathford, and others were sent up to London to represent Scotland in the Assembly at Westminster. The "Solemn League and Covenant," after undergoing some slight alterations, passed the two Houses of Parliament and the Westminster Assembly, and thus became law for the two kingdoms. By means of it Henderson has had an extraordinary influence on the history of Great Britain. As Scottish commissioner to the Westminster Assembly, he was in England from August 1643 till August 1646, and the action of the Scottish commissioners gave a fresh impulse to English Presbyterianism. Early in 1645 Henderson was sent to Uxbridge to aid the commissioners of the two parliaments in negotiating with the king, but nothing came of the conference. In 1646 the king joined the Scottish army, and, after conferring with them to New-

castle, he sent for Henderson, and discussed with him the two systems of church government in a number of papers. Meanwhile Henderson was failing in health. He sailed to Scotland, and eight days after his arrival died on the 19th of August 1646. He was buried in Greyfriars Churchyard, Edinburgh, and his death was the occasion of national mourning in Scotland. An absurd story was at once invented to the effect that, after recanting to the king's views, he had died of remorse. A document was forged, purporting to be a "Declaration of Mr Alexander Henderson," and, although this paper was disowned, denounced, and shown to be false in the General Assembly of August 1648, the fiction was used by Clarendon, and still finds a place in professedly historical compilations.

Henderson is one of the greatest men in the history of Scotland, and, next to Knox, is certainly the most famous of Scottish ecclesiastics. He had great political genius, and his statesmanship was so influential that "he was," as Professor Masson well observes, "a cabinet minister without office." He has made a deep mark on the history, not only of Scotland, but of England, and the existing Presbyterian Churches in Scotland are largely indebted to him for the forms of their dogmas and their ecclesiastical organization. He is thus justly considered the second founder of the Reformed Church in Scotland.

For further information about Henderson reference may be made to *McClure's Life of Alexander Henderson*, 1810; *Aston's Life and Times of Alexander Henderson*, 1836; *The Letters and Journals of Robert Burns*, 1811-2 (an exceedingly valuable work, from an historical point of view); *Burton's History of Scotland*; *McClure's Life of Dr James Henderson*; *Edinburgh*, and, above all, *Brown's Life of Milton*. (T G)

HENDERSON, ERNEST WILLIHELM, Scottish dissenting minister and theologian and miscellaneous writer, was born at the Linn near Dunfermline, November 17, 1784, and died at Murtleke, May 17, 1858. He was the youngest son of an agricultural labourer, and after three years' schooling spent some time at watchmaking and as a shoemaker's apprentice. In 1803 he joined Mr Robert Haldane's theological seminary, and in 1805 was selected to accompany the Rev John (afterwards Dr) Paterson to India, but as the East India Company would not allow British vessels to convey missionaries to India, Henderson and his colleagues went to Denmark to await the chance of a passage to Serampore. Being unexpectedly delayed, they ultimately decided to settle in Denmark, and in 1806 Henderson was fixed at Elsinore. From this time till about 1817 he was engaged in encouraging the distribution of Bibles in the Scandinavian countries, and in the course of his labours he visited Sweden and Lapland (1807-8), Iceland (1814-15), and the mainland of Denmark and part of Germany (1816). During most of this time he was an agent of the British and Foreign Bible Society. In 1818, after a visit to England, he travelled in company with Dr Paterson through Russia as far south as Tiflis, but, instead of settling as was proposed at Astakhan, he had to retrace his steps, having resigned his connexion with the Bible Society. In 1822 he was invited by Prince Alexander Galitzin to assist the Russian Bible Society in translating the Scriptures into various languages spoken in the Russian empire. After twenty years of foreign labour Henderson returned to England, and in 1825 was appointed tutor of the Mission College, Gowerport. In 1830 he succeeded Dr William Harrison as theological lecturer and professor of Oriental languages in Highbury Congregational College, and though in 1850, on the amalgamation of the colleges of Hoxton, Coward, and Highbury, he was excluded from office through age, he was pastor in 1852-53 of a chapel at Murtleke. His last work was a translation of the book of Ezekiel. Henderson was a man of great linguistic attainments in the course of his

labours, he made himself more or less acquainted, not only with the ordinary languages of scholarly accomplishment and the various members of the Scandinavian group, but also with Hebrew, Syriac, Ethiopic, Russian, Asiatic, Tatar, Persian, Turkish, Armenian, Manchoo, Mongolian, and Coptic. He organized the first Bible Society in Denmark (1814), and paved the way for several others. In 1817 he was nominated by the Scandinavian Literary Society a corresponding member, and in 1840 he was made D.D. by the university of Copenhagen. He was honorary secretary for life of the Religious Tract Society, and one of the first promoters of the British Society for the Propagation of the Gospel among the Jews. The records of his travels in Iceland (1818) were valuable contributions to our knowledge of that island. His other principal works are *Biblical Researches and Travels in Russia* (1826), *Dynastic Inspiration* (1836), and annotated translations of Isaiah (1840, 1857), the twelve minor prophets (1845), and Jeremiah (1851).

See *Memoirs of Ernest Henderson*, by Thalia S. Henderson (hus daughter), London, 1859.

HENGSTENBERG, ERNEST WILLIHELM (1802-1860), for more than forty years one of the most conspicuous and able champions of the strictest Lutheran orthodoxy, was born at Frondenberg, a Westphalian village, near Hamm and not far from the Rhine, on October 29, 1802, received his entire school education under the roof of his father, who was a minister of the Reformed Church, and head of the Frondenberg Fismalstift, and entered the university of Bonn in 1819, shortly before the completion of his seventeenth year. There he attended the lectures of Fieytag and Gieseler on Old Testament exegesis and church history, but his energies were principally devoted to philosophy and philology, and his earliest publication was an edition of the *Modalitah* of Amir Y. Kair (*Amirliche Modalitah nach scholastischen edult, latine verit, et illustant G. F. H.*, 1833), which gained for him the prize at his graduation in the philosophical faculty, and the public commendation of Sylvester de Sacy. This was followed in 1821 by a German translation of Aristotle's *Metaphysica*. On quitting Bonn it had been Hengstenberg's wish to complete his theological studies under Neander and Tholuck in Berlin, but finding himself without the means of doing so, he accepted for a year a situation at Basel as tutor in Oriental languages to J. J. Stahelin. Then it was that, suffering much from ill-health and deeply mourning the loss of his mother, he began to direct his attention, with an ardent formerly unknown to him, to the spiritual truths of the Bible. His studies and experiences at this crisis resulted in a conviction, never afterwards shaken, not only of the divine character of evangelical religion, but also of the unquenchable adequacy of its expression in the Augsburg Confession. Taking as his motto Psalm cxviii. 17, he resolved thereupon to devote himself to the uncompromising defence of that word. In the autumn of 1824 he joined the philosophical faculty of Berlin as a privat-docent, and in the following year he became a licentiate in theology, his thesis even then being remarkable for their evangelical fervour and for their emphatic protest against every form of "rationalism," especially in questions of Old Testament criticism. In 1826 he became professor extraordinary in theology, and in July 1827 appeared under Hengstenberg's editorship the first number of the *Evangelische Kirchenzeitung*, a "rationalist" journal which in his hands was destined to acquire an almost unique reputation as an organ of religious, theological, and ecclesiastical controversy. It did not, however, attain to great notoriety until in 1830 an anonymous article (by E. L. von Geilach) appeared, which openly charged Professors Gesenius and Wegscheider with infidelity and profanity, and on the ground of these accusations advo-

cated the interposition of the civil power, thus giving rise to the prolonged "Halleische Streit" as it was called, which was at least effectual in giving the public a due impression of the energy and zeal of the new "evangelical" school. In 1828 the first volume of Hengstenberg's *Christologie des Alten Testaments* passed through the press, in the autumn of that year he was promoted to the dignity of professor ordinarius in theology, and in 1829 he married. The remainder of his life, apart from the excitement which its various literary activities imparted to it, was uneventful. He died on the 28th of May 1869.

The following is a list of the principal works of Hengstenberg—*Christologie des Alten Testaments* (1829-36, 2d ed. 1864-57, Eng. transl. by R. Kith, 1835-39, also in Cluck's, "Foreign Theological Library," by Th. Meyer and J. Mutin, 1864-68), a work of much ingenuity and wide knowledge, but which will be differently valued according to the hermeneutical principles of the individual critic, *Beitrag zur Einleitung in das Alte Testament* (1831-39, Eng. transl. by J. K. L. L.), "Dissertations on the genuineness of Daniel and the Integrity of Zechariah," Edin., 1848, and "Dissertations on the genuineness of the Pentateuch," Edin., 1847, in which the traditional view on each question is strongly upheld, and much capital is made of the absence of humanity among the negative critics, *Die Fiktion Moses und Balaam* (1841), spoken of by Daxel as "perhaps Hengstenberg's most meritorious work," *Die Geschichte Israels in seinen Passagenen* (1842, translated into English along with the Dissertations on Daniel and Zechariah mentioned above), *Commentar über die Psalmen* (1842-45, 2d ed. 1849-52, Eng. transl. by Paulus and Thomson, 1850), in which the merits and defects of the *Christologie*, *Die Offenbarung Johannes erläutert* (1841-51, 2d ed. 1861-62, Eng. transl. by Paulus, 1850), in Cluck's "Foreign Theological Library," 1861-63), *Das Hohelied ausgelegt* (1850), *Die Propheten Jeremia erläutert* (1850), *Das Evangelium Johannes erläutert* (1861-63, 2d ed. 1867-71, Eng. transl. 1868), and *Die Weissagungen des Propheten Ezechiel erläutert* (1867-68). Of minor importance are *De rebus Tyronum commentatio academica* (1833), *Uebn. den Tag der Ernte* (1839), *Das Psalm*, *im Vortrag* (1855), and *Die Orgel des heiligen Schrift* (1859). Several series of papers also, as, for example, on "The Institution of the Eucharist," "The century," "The year," and "The Relation between the Jews and the Christian Church," which originally appeared in the *Kirchenzeitung*, were afterwards printed in a separate form. *Geschichte des Reiches Gottes unter dem Alten Bund* (1869-70), *Das Buch Jeremia erläutert* (1870-75), and *Fortsetzung über die Leiden und Geschichte* (1875) were published from Hengstenberg's papers, posthumously. See Bachmann's *Ernst Hengstenberg* (1876-77), also his article in Harzog and Plitt's *Biographisches* (1870).

HENKE, HEINRICH PHILIPP KONRAD (1752-1809), a learned German theologian of the broad school, best known as a writer on church history, was born at Hahlen, Brunswick, on July 3, 1752, was educated at the gymnasium of Brunswick and the university of Helmstedt, and from 1778 until his death, which occurred on May 2, 1809, held a professorship of theology in that university. His principal work (*Kirchengeschichte*, in 6 vols., 1788-1804, 2d ed. 1793-1806) is commended by Baur for fullness, accuracy, and artistic composition, as one of the best in that class of literature. His other works are *Elementa institutionum fidei Christianae*, *Insuper ordinum* (1789), *Opuscula Academicum* (1802), and two volumes of *Prædicationes*. His son, Ernst Ludwig Theodor (1804-1872), has also left a name in the literature of theology and ecclesiastical history, having been the author of monographs upon *Georg Calixtus et seine Zeit* (1853-60), *Papst Pius VII.* (1860), *Konrad von Marburg* (1861), *Kusanus Pöcher u. Nik. Krell* (1866), *Jak. Friedr. Fries* (1867), as well as of other works.

HENLEY, JOHN (1692-1759), an eccentric clergyman of the last century, commonly known as "Orator Henley," was born August 8, 1692, at Melton-Mowbray, where his father was vicar. After attending the grammar schools of Melton and Oakham, he in his seventeenth year entered St John's College, Cambridge, and while still an undergraduate he addressed, in February 1712, under the pseudonym of Peter de Quen, a letter to the *Spectator* displaying no small wit and humour. After graduating B.A. he became assistant and then head-master of the

grammar school of his native town, uniting to these duties those also of assistant curate. His superabundant energy was not, however, fully consumed by this plurality of offices, for besides publishing in 1714 a poem entitled *Esther, Queen of Persia*, containing many vigorous and eloquent passages, he also devoted his attention to the compilation of a grammar of ten languages entitled *The Complete Linguist* (3 vols., London, 1719-21). In his school he is said to have introduced many new methods of study, but whether it was that his innovations were not sufficiently appreciated, or that he desired a wider sphere for the exercise of his exceptional abilities, he resolved to place his services at the disposal of the metropolis, where he arrived with thirty recommendatory letters from some of the most influential persons of his native county. He succeeded in obtaining the appointment of assistant preacher in the chapel of Ormond Street and Bloomsbury, and in 1723 was presented to the rectory of Chelmsford in Suffolk, but residence being insisted on, he resigned both his appointments, and on July 3, 1726, opened what he called an "oratory" in Newport Market, which he licensed under the Toleration Act. Into his services he introduced many peculiar alterations: he drew up a "Primitive Liturgy," in which he substituted for the Nicene and Athanasian creeds two creeds taken from the apostolical constitutions, for his "Primitive Eucharist" he made use of unleavened bread and mixed wine, he distributed at the price of one shilling medals of admission to his oratory, with the device of a man rising to the meidian, with the motto *Ad summam*, and the words *Inveniam viam aut faciam* below. But the most original element in the services was Henley himself, who is described by Pope in the *Dunciad* as "Piercean at once and rarer of his age."

He possessed some oratorical ability and adopted a very theatrical style of elocution, "tuning his voice and balancing his hands," and his addresses were a strange medley of solemnity and buffoonery, of clever wit and the wildest absurdity, of able and original disquisition and the worst artifices of the oratorical cabalists. His services were much frequented by the "free thinkers," and he himself expressed his determination "to die a rational." Besides his sermons on Sunday he delivered on Wednesday lectures chiefly on social and political subjects, and he also projected a scheme for connecting with this "oratory" a university on quite a novel plan, and intended to be, in a sense too utopian to be realized, the foster-mother of the arts and sciences. For some time he edited the *Ilyp Doctor*, a weekly paper established in opposition to the *Critic*, and for this service he enjoyed a pension of £100 a year from Sir Robert Walpole. At first the orations of Henley drew great crowds, but, although he never discontinued his services, his audience latterly dwindled almost entirely away. He died 18th October 1759.

Henley is the subject of several of Hogarth's prints. His life, professedly written by A. Walpole, but in all probability by himself, was inserted by him in his *Oratorical Transactions*. See Nichol's *History of Leicestershire*, and Duncanson's *Catena of Authors*.

HENLEY-ON-THAMES, a market-town of Oxfordshire, England, is situated on the left bank of the Thames and at the terminus of a branch of the Great Western Railway. It is 22 miles S of Oxford and 35 W from London by rail, and 47 miles from Oxford and 6½ from London by the river. It occupies one of the most beautiful situations on the Thames, at the foot of the finely wooded Chiltern Hills. The river is crossed by an elegant stone bridge of five arches, constructed in 1738 at a cost of £10,000. The principal buildings are the parish church, a handsome Gothic structure recently restored at a cost of over £7000, possessing a lofty tower of intermingled flint and stone, which is attributed to Cardinal Wolsey, but which was more pro-

It was erected by Bishop Longland, the grammar school, in 1603, the town hall, a neat building supported by Doric columns, the reading-room and library, and several charitable institutions. Henley is a favourite resort, and also possesses some trade in corn, flour, and timber. It is celebrated for the Henley Royal Regatta, the principal gathering of amateur oarsmen in England, which usually takes place in July. The population of the parish in 1871 was 3736, and of the local board district 4623.

It was erected at a very early period, and according to some authorities was a Roman station. It obtained a charter of incorporation from Elizabeth, in which it is named *Henleigge* or *Henbury*. In 1643 it was occupied by the Parliamentary forces, who successfully repelled an attack made upon it by the Royalists.

See *History of Henley-on-Thames*, by John Southern, Duane, London, 1861, and *An account of the Battle of the Annual Henley Regatta from their commencement June 1889 to the year 1879*, Henley, 1879.

HEENNA is the Persian name for a small shrub found in the East Indies, Persia, the Levant, and along the African coasts of the Mediterranean, where it is frequently cultivated. It is the *Zinnia m. alba* of botanists, and from the fact that young trees are spinescent, while older ones have the branches hardened into spines, it has also received the name of *Zinnia vermicis* and *Z. spinosa*. It forms a slender, shrubby plant of from 8 to 10 feet high, furnished with opposite oval-lanceolate smooth leaves, which are entire to the margins, and bear small white four petalled sweet-scented flowers disposed in panicles. The four spreading petals are obovate, and furnished with claws, and alternating with them are eight stamens approximating by point. Its Egyptian name is *Khenna*, its Arabic name *Al Alouana*, its Indian name *Mendea*, while in England it is called *Egyptian privet*, and in the West Indies, where it is naturalized, *Egyptian mignonette*.

It was in Hené as of ancient repute as a cosmetic. This consists of the leaves of the *Zinnia* powdered and made up into a paste, this is employed by the Egyptian women, and also by the Malabar women in India, to dye their henna nails and other parts of their hands and feet of an orange red colour, which is considered to add to their beauty. The colour lasts for three or four weeks, when it is renewed. It is moreover used for dyeing the hair and beard, and even the manes of horses, and the same material is employed for dyeing skins and mooseclothes a reddish yellow, but it contains no tannin. The practice of dyeing the nails was common amongst the Egyptians, and not to conform to it would have been considered indecent. It has descended from very remote ages, and is proved by the evidence afforded by Egyptian mummies, some of which are most commonly stained of a reddish colour.

It is also said to have been held in repute by the Hebrews, being considered to be the plant which is alluded to in the Bible (Song of Solomon iv. 13). "The custom of dyeing the nails and of the hands and soles of the feet of an ornament with henna," observes Dr. Royle, "exists throughout the Mediterranean from the Ganges, as well as from Africa. In some parts the practice is not confined to women and children, but is also followed by men, as in Persia. In dyeing the beard, the hair is treated by the application, which is then changed to black by the use of indigo. In dyeing the hair of children, the tails and manes of horses and asses, the process is the same. It is also used to dye the hair of the horse to stop at the red colour which the henna produces."

"Mahomet," it is said, used henna as a dye for his beard, and the fashion was adopted by the caliphs. The "henna," remarks Lady Calcott in her *Scriptures Illustrated*, "is scarcely to be called a caprice in the East. There is a quality in the drug which gently restores perspiration in the hands and feet, and produces an agreeable coolness equally conducive to health and comfort." She further suggests that if the Jewish women were not in the habit of using this dye before the time of Solomon, it might probably have been introduced amongst them by his wife, the daughter of Pharaoh, and thence to this probability the allusion to "camellie" in the passages in Canticles above referred to.

The preparation of henna consists in reducing the leaves and young twigs to a fine powder, catechu or liquid leaves in a pulverized state being sometimes mixed with them. When required for use, the powder is made into a paste with warm hot water, and is then spread upon the part to be dyed, where it is generally allowed to remain for one night.

It has been already noted that the flowers of the *Zinnia* are very fragrant, whence they derive in the West Indies the name of *Egyptian mignonette*. According to Lady Calcott, they are often used by the eastern women to adorn their hair, and Mr. Summons states that the distilled water from the flowers is used as a perfume. The plant is further credited with the possession of vulnerary and astringent properties.

HENNEDONT, a town of France, arrondissement of Lorient, and department of Morbihan, is situated on the Blavet, not far from its mouth, about 15 miles W.N.W. of Vannes. It is a picturesque old town, and contains some remains of its former fortifications. The church of Notre Dame de Paradis, a beautiful building of the 16th century, possesses some fine wood carving. The town has an important corn-market, and considerable shipping trade in iron, corn, honey, wax, hemp, cider, and wine. Shipbuilding, sawing, and tanning also carried on. Henedont is famed for the resistance which it made, under the widow of John du Montfort, when besieged by the armies of Philip of Valois and Charles of Blois. The population in 1876 was 4844.

HENNEQUIN, PAUL-ÉTIENNE (1763-1833), French painter, was a pupil of David. He was born at Lyons in 1763, distinguished himself early by winning the "Grand prix," and left France for Italy. The disturbances at Lyons, during the course of the Revolution, obliged him to return to Paris, where he executed the Frescoes of the 11th of July, and visiting his native town was at work there on a large design commissioned for the town hall, when in July 1794 he was accused before the revolutionary tribunal and thrown into prison. Hennequin escaped, only to be anew accused and imprisoned in Paris, and after running great danger of death, seems to have devoted himself thenceforth wholly to his profession. At Paris he finished the picture ordered for the municipality of Lyons, and in 1801 produced his chief work, *Orestes pursued by the Furies* (Louvre, engraved by London, *Anales de l'Art*, vol. i. p. 106). He was one of the four painters who competed when in 1802 Goss called off the official pug for a picture of the Battle of Marengo, and in 1808 Napoleon himself ordered Hennequin to illustrate a series of scenes from his German campaigns, and commanded that his picture of the Death of General Salomon should be engraved. After 1815 Hennequin retired to Laigle, and there, aided by subventions from the Government, carried out a large historical picture of the Death of the Three Hundred in defence of Luvo—a sketch of which he himself engraved. In 1824 Hennequin settled at Tournay, and became director of the academy, he exhibited various works at Lille in the following year, and continued to produce actively up to the day of his death, which took place in May 1833. The *Orestes* of the Louvre is his capital work, it shows a certain style and finish of draughtsmanship, but the attitudes are melodramatic, the composition stagg, and the colour false and violent.

HIENNERSDORF, or SHITTENERSDORF, a manufacturing village of Saxony, in the circle of Bautzen and 20 miles S.S.E. of the town of that name. The inhabitants are engaged in weaving and bleaching, and in the manufacture of woollen goods, satin, amette, machinery, bricks, and wooden shoes. There is also an iron foundry. Population (1875), 6366.

HENRIETTA MARIA (1609-1666), queen of Charles I. of England, born November 25, 1609, was the daughter of Henry IV. of France. When the first overtures for her marriage were made on behalf of Charles, prince of Wales, in the spring of 1623, she was little more than fourteen years of age. Her brother, Louis XIII., only consented to the marriage on the condition that the English Roman Catholics were relieved from the operation of the penal laws. When therefore she set out for her new home in June 1625, she had already pledged the husband to whom she had been married by proxy on May 1 to a course of action which was certain to bring unpopularity on him as well as upon herself.

Her husband was now king of England. The early years of the married life of Charles I. were most unhappy. He soon found an excuse for breaking his promise to relieve the English Catholics. His young wife was deeply offended by treatment which she naturally regarded as unkindness. The favourite Buckingham stirred the flames of his master's discontent. Charles in vain strove to induce her to tame his submission. After the assassination of Buckingham in 1628 the barrier between the married pair was broken down, and the bond of affection which from that moment united them was never loosened.

For some years Henrietta Maria's chief interests lay in her young family, and in the amusements of a gay and brilliant court. She loved to be present at dramatic entertainment, and her participation in the private rehearsals of the *Shepherd*, *Pastoral*, written by her favourite Walter Montague, probably drew down upon her the savage attack of Dryden. With political matters she hardly meddled as yet. Even her co-religionists found little aid from her till the summer of 1637. She had then recently opened a diplomatic communication with the see of Rome. She appointed an agent to reside at Rome, and a papal agent, a Scotchman named Con, accredited to her, was soon engaged in effecting conversions amongst the English gentry and nobility. Henrietta Maria was well pleased to become a patroness of so holy a work, especially as she was not asked to take any personal trouble in the matter. Protestant England took alarm at the proceedings of a queen who associated herself so closely with the doings of "the grim wolf with pretty paw."

When the Scottish troubles broke out, she raised money from her fellow Catholics to support the king's army on the border, in 1639. During the session of the Short Parliament in the spring of 1640, the queen urged the king to oppose himself to the House of Commons in defence of the Catholics. When the Long Parliament met, the Catholics were believed to be the authors and agents of every military scheme which was supposed to have entered into the plans of Stafford or Laud. Before the Long Parliament had sat for two months, the queen was urging upon the pope the duty of lending money to enable her to restore her husband's authority. She threw herself heart and soul into the schemes for raising Stafford and covering the palace mount. The army plot, the scheme for using Scotland against England, and the attempt upon the five members were the fruits of her political activity.

In the next year the queen effected her passage to the Continent. In February 1643 she landed at Burlington Quay, placed herself at the head of a force of royalists, and marched through England to join the king near Oxford. After little more than a year's residence there, on April

3, 1644, she left her husband to see his face no more. At Easter she gave birth to her youngest child, who was one day to be duchess of Orleans, and to negotiate the treaty of Dover. Henrietta Maria found a refuge in France. Richelieu was dead, and Anne of Austria was compassionate. As long as her husband was alive the queen never ceased to encourage him to resistance.

During her exile in France she had much to suffer. Her husband's execution in 1649 was a terrible blow. She brought up her youngest child, Henrietta in her own faith, but her efforts to induce her youngest son, the duke of Gloucester, to take the same course only produced discomfort in the exiled family. The story of her marriage with her attached servant Lord Fernyn needs more confirmation than it has yet received to be accepted, but all the information which has reached us of her relations with her children points to the estrangement which had grown up between them. When after the Restoration she returned to England, she found that she had no place in the new world. She received from parliament a grant of £30,000 a year in compensation for the loss of her dower-lands, and the king added a similar sum as a pension for herself. In January 1661 she returned to France to be present at the marriage of her daughter Henrietta to the duke of Orleans. In July 1662 she set out again for England, and took up her residence once more at Somerset House. Her health failed her, and on June 24, 1666, she departed in search of the climate of her native country. She died on August 31, 1666, at Columbe, not far from Paris.

HENRY I. (1068-1133), king of England, fourth and youngest son of William the Conqueror and Matilda of Flanders, was born some time in the autumn of 1068. Local tradition fixes his birthplace at Sally in Yorkshire. Little is known of his earlier life, except that he received an unusually good education, and attained a proficiency rare among the princes of his day. In 1086 he was dubbed knight. Next year his father bequeathed to him on his deathbed a sum of five thousand pounds, and he said to have foretold that he would eventually be king. Condemned by the division of the Conqueror's territories, to a position of inferiority to his two brothers, he used his legacy to improve that position. Robert, being in need of money, sold him the districts of the Cotentin and the Avranchin, which he held of his brother as a fief. His relations with Robert were not always friendly, but he defended Normandy against Rufus, and aided his liege lord in putting down a revolt in Rouen. Nevertheless, in the treaty between William and Robert made in 1091, he was excluded from the succession, and soon afterwards was deprived of his lands in Normandy.

The testament he met with from Robert was not likely to make him support the terms of the treaty of 1091. Immediately after the death of Rufus, he rode to Winchester, and seized the royal hoard in that city. Next day (August 3, 1100) he was elected king by such of the witan as were present, and on Sunday, August 6th, he was crowned at Westminster. In order to conciliate the clergy and the nation, he recalled Anselm, imprisoned Ranulf Flambard, and issued a comprehensive charter of liberties. Before the year was out he married Matilda, daughter of Malcolm and Margaret, and great granddaughter of Edmund Ironside, a step which greatly strengthened his otherwise insecure title to the crown. The alliance thus contracted with the church and the nation was his constant support in the struggle with his brother and his wily vassals, which began immediately. It resulted in the conquest of Normandy, the temporary suppression of feudalism, and the consolidation of royal power on both sides of the Channel. Robert, as soon as he returned from the Holy Land, attempted with the aid of a conspiracy in

England to wrest the crown from the usurper. He landed at Portsmouth (August 1, 1101), but before a blow was struck the brothers came to terms. Robert recognized Henry as king of England, and returned to Normandy. Henry's vengeance fell upon his brother's partisans, and Robert of Belesme and several others were banished from the country and lost their English estates. Secure in England, Henry carried the war into the enemy's country. His brother's misgovernment gave him both pretext and opportunity. After two or three expeditions, the struggle was brought to a close by the battle of Tenchebraie (September 28, 1106), in which Robert was taken prisoner. He remained in captivity till his death in 1134, and Normandy passed into the possession of the English king. This conquest at once brought Henry into collision with France. Louis the Fat was a constant supporter of Henry's rebellious vassals, and of his rival and nephew, William, son of Robert. Henceforward Henry had to spend most of his time in the duchy. A war with France (1111-1113) ended in a peace which brought some advantages to Henry. Louis gave up his claim to the sovereignty of Maine and Brittany, and Henry was able to carry his old opponent, Robert of Belesme, to England, where he was imprisoned for the rest of his life. Henry had already, though in vain, attempted to secure the aid of Flanders by two treaties with Count Robert (1103, 1108). He now sought a mightier ally in the emperor, Henry V., to whom he married his daughter, Matilda (January 7, 1114). Another war with France, which broke out in 1116, and in which Louis took up the cause of William, son of Robert, against his uncle, was marked by the battle of Noyon (1119). At a council at Rheims (1119) Louis accused Henry before Pope Calixtus of rebellion and usurpation. Henry, however, pleaded his own cause before the pope at Gisors so persuasively that Calixtus brought about a peace between the two kings (1120) on the basis of a mutual restoration of conquests. During the war Henry had suffered a severe loss in the death of his queen Matilda. He now felt it more than ever necessary to take measures for securing the succession to his only son William. The barons of Normandy and England were made to do homage to the young prince (1119), who shortly afterwards married Matilda, daughter of Fulk of Anjou, an alliance by which Henry hoped to turn a dangerous foe into a firm friend, and to secure at least the chance of a rich inheritance. All these hopes were, however, shattered by the death of William (1120). Deprived of an heir to his throne, Henry now married Adela, daughter of Godfrey, count of Louvain (1121), but the marriage unfortunately proved childless. Shortly afterwards another rebellion, headed by Count Waleran of Meulan, broke out in Normandy (1123). The rebels were emboldened by the ascent of the king of France and the count of Anjou, but were entirely defeated at Bourgthéroule (1124). The terrible vengeance taken by Henry on this occasion, together with the death of William, son of Robert, in 1128, seems to have finally crushed the opposition in Normandy. The death of Duke Robert in 1134 removed the last object round which the schemes of rebellion or the intrigues of France could centre. Meanwhile Henry had recalled his daughter Matilda, now a widow, from Germany. In default of an heir to the throne, he made this widow swear to accept her as Lady of England and Normandy (Christmas 1126). Next year he gave her in marriage to Godfrey, son of Fulk, count of Anjou, hoping thereby to secure the objects frustrated by the death of his son. Fate, however, thwarted the immediate success of these schemes.

The annals of England, after the expulsion of Robert of Belesme, are uneventful. In his ecclesiastical policy Henry, without giving up the control over the church which

his father had asserted, was forced to recognize to a certain extent the advancing claims of Rome. His disputes with Anselm were conducted with good temper on both sides, and was brought to a satisfactory conclusion. Anselm had made no objection to the ecclesiastical supremacy claimed by Rufus, but the decrees of the Lateran Council (1059) obliged him to resist a similar claim when put forward by Henry I. He refused to do homage to his new king, or to consecrate the bishops whom Henry invested, according to ancient custom, with the symbols of ecclesiastical dignity. Neither side would give way. Henry continued to make bishops as before, and Anselm refused to consecrate them. In 1103 he left England. For the next three years the affairs of Normandy hindered the settlement of the question, but a compromise was effected in 1107. The pope, Paschal II., consented that homage should be done to the king, while Henry gave up his claim to investiture with the ring and staff. The question thus settled was not reopened till the days of Becket. In other respects Henry acquiesced in the tendency of the time towards ecclesiastical separatism, and countenanced the decrees of the synod of 1102, which forbade the marriage of the clergy and the tenure of temporal offices by ecclesiastics. He showed his care for the church by the establishment of two new sees, those of Ely (1109) and Carlisle (1133), taken respectively from the unwieldy dioceses of Lincoln and York. In the old quarrel between York and Canterbury, Henry supported the claims of the southern metropolitan against Archbishop Thurstan. On Anselm's death, Henry was guilty of leaving the see vacant for five years, but in his other dealings with the church he seems to have been actuated by worthy motives. He refused, however, to open her high places to Englishmen, and till near the end of his reign no native attained the dignity of prelate. The same exclusive spirit made itself felt in the appointments to temporal office. But although political liberty and influence were not given to Englishmen under Henry I., the English nation as a whole acquiesced gladly in his rule. His chief wants were justice and order, and protection from feudal tyranny, and these blessings it obtained. The necessities of his position compelled Henry to rely mainly on his English subjects. As a counterpoise to the local influence of the barons, he did his best to reactivate the old popular institutions of the hundred and the county-court, of tithings and frankpledge, of watch and ward. His frequent progresses through the country, for judicial and other purposes, form a link between the annual courts held by the Conqueror and the regular circuits of the justices established by Henry II. In the administration of justice and the tools of government he relied on new men, raised from the ranks and dependent on himself for their position. The old baronage he habitually depressed, and every unsuccessful rebellion thinned the ranks of the feudal nobility, while it tightened the link between the king and the nation.

Thus secure at home, Henry was dreaded by his neighbours within the four seas. Over Scotland, Ireland, and Wales a sort of ecclesiastical supremacy was recognized. On the northern frontier there was peace throughout the reign, on the western there was more disturbance. Henry settled a colony of Flemings in Pembroke (1111), and made two expeditions into Wales (1114, 1121), in one of which he received the submission of several Welsh princes. The profound peace which England enjoyed for a period of thirty-four years is the best testimony to Henry's merits as a king. As a man his character is not admirable, not yet wholly to be condemned. He was hard, mercenary, and unforgiving, but not wantonly cruel. He sometimes displayed a grim humour which reminds one of his father, but he never gave way to the vices and brutality of Rufus, nor to the jovial good-humour which was so winning in his

eldest brother. Regarded as the "Lion of Justice" by his people, and bitterly regretted after he was gone, he was not a popular king. He died, after bequeathing his crown to his daughter Matilda, near Rouen (December 1, 1135). His body was carried to England, and buried in the abbey he had founded at Reading.

HENRY I. (1133-1189), king of England, son of Geoffrey, count of Anjou, and Matilda, daughter of Henry I, was born at Le Mans, March 5, 1133. He was left in France during the first part of his mother's struggle with Stephen, but was sent over to England in 1141. There he remained four years, in the charge of his uncle, Robert of Gloucester. In 1147 he took a more active part in the war, but was not successful. He now sought the aid of David, king of Scotland, and was knighted by him (1149), but nothing came of this alliance with that prince. On his return to England (1151), he was crowned king, and upon him, and later in the year he became, by his father's death, the crown of England. In 1152 he married Eleanor of Aquitaine, and added Poitou and Guienne to his dominions. He again went to England in 1153, and the great position he had won on the Continent turned the scale in his favor. After a short struggle Stephen consented to negotiate. By the treaty of Winchester (November 7, 1153) it was settled, among other things, that Stephen should reign undisturbed during the rest of his life, and that Henry should succeed him. A year later Stephen died, and Henry took the throne, possessing himself of the crown on December 19, 1154, and at once issued a charter of liberties, in which he confirmed the charter of Henry I.

He was the eldest son of the earlier Sir Henry
 of the same name, who falls into the 12th century. His first
 Henry was occupied in restoring and maintaining order.
 The second is that of the quarrel with Becket. The third
 is for the most part a period of rebellion and trouble, the
 consequences of that quarrel Henry's first business was
 to fulfil the promises made in the treaty of Winchester, and
 to undo the work of his predecessor. Several of Stephen's
 knights were slain, and the king's army was defeated. The
 rebellious nobles destroyed the royal domain, recovered the
 In this task the king met with little serious opposition, and
 his presence generally sufficed to ensure success. In 1166
 Henry was able to go to France, where his brother Geoffrey was
 causing trouble by his claims on Anjou. He had to
 subdue him by force of arms, after which he allowed him
 to marry the daughter of the king of Castile, in exchange for
 his homage. He then returned to England, and in 1171 he
 from his Continental vassals, and humbled the barons of
 Louis VII. At Easter 1187 he returned to England, to
 complete the restoration of order there. Those of the greatest
 barons who had not yet given up their castles had now to
 do so, and the king of Scotland surrendered the three
 northern counties. An unsuccessful expedition to Wales was
 followed in 1188, on his brother Geoffrey's death. Henry
 followed in 1189, on the death of his brother Geoffrey.
 his second son Henry (the eldest, William, being dead) to
 Marzette, daughter of Louis. Next year he made an attack

upon Toulouse, which he claimed in right of his wife, but after some successes retired, owing to the opposition of the French king. In a peace made soon after, he retained Cahors, but gave up his claim to the rest of the county. Hostilities between him and Louis were, however, more or less continuous during this time, in spite of the efforts of Alexander III. In January 1163 Henry returned to England after five years' absence, and his quarrel with Becket immediately began.

Becket had been consecrated archbishop of Canterbury in June 1162. He at once resigned his temporal offices, and demanded the restitution of lands alienated from his see. At a council at Woodstock he refused to pay the tax of two shillings per hide demanded by the king. A little later the struggle was removed to still more dangerous ground. Becket refused his consent to the king's proposal for settling the dispute between the temporal and spiritual courts. Upon this Henry asked him and the bishops whether they would abide by the ancient customs of the realm. So vague a question met with an evasive answer. The bishops would not say yes or no. However, when the council of Clarendon (January 1164) the disputed customs were drawn up in the form of sixteen constitutions, and after considerable hesitation accepted by Becket. He nevertheless took absolution from the pope, who refused to confirm the constitutions. Henry now attacked Becket with a series of charges connected with his chancellorship, the result of which the latter evaded by leaving England. Henry took possession of the see, and expelled Becket's friends and relations. The greater part of the next five years he spent abroad. During this time he was occupied in maintaining order among his unruly vassals, checking the intrigues of Louis, and negotiating with the pope. He also obtained possession of Breteuil, the old fortress, and of Richbourg, the castle of Alice, daughter of Louis. With the object of securing the succession he had his son Henry crowned by the archbishop of York at Westminster (June 1170). The young king's wife was not crowned with him, Louis, taking this as an insult, invaded Normandy, and only made peace with Henry on condition that he would restore Becket to favour. A meeting between the king and the archbishop ended in a compromise, and the latter returned to England. His first step was to suspend the archbishop of York and other bishops who had taken part in the coronation of the young king, and Henry, on hearing of this, uttered the angry words that led to Becket's murder. The pope was, however, in too critical a position to take any seriously hostile line. He sent legates to France, and then met and negotiated with the legates at Avanches (1172), in which Henry consented to absolution, and promised to abolish all the bad customs introduced during his reign. He had employed the interval in making an expedition to Ireland, and appropriating the conquests made by Strongbow a few years before.

The ecclesiastical quarrel seemed to have died away, but its consequences were felt in the great rebellion of 1173. A conference was organized by the French king, the count of Flanders, the king of Scotland, and Henry's sons, with the object of placing the young Henry on his father's throne. The English nobles, however, were not so widely favourable to the king. In view of a general attack which was to be made next year, Henry crossed over to England and did penance at Becket's tomb. Fortunately his justiciars, De Lucy, captured the Scotch king at Alnwick, and the rebellion in England was speedily put down. William the Lion was forced to buy his release by doing homage to Henry, the other co-rebels were pardoned, and peace was made. Henry then visited over his father, and proceeded to secure his position by further legislative enactments, and henceforward he had no trouble in England. But he was

involved in constant difficulties with his sons and with the French king, owing to the mutual jealousies of the former and the intrigues of the latter, to which Henry's partiality for his youngest son John and his refusal to allow the marriage of Richard with Alice gave rise. A war between the brothers in 1183 was brought to an end by the death of the young Henry in the same year. The feud broke out again in 1184, and continued at intervals, in spite of the death of Geoffrey in 1186, to the end of the reign. At length Henry's apparent intention to name John as his successor forced Richard to ally himself with Philip II., and in the war that followed Henry was beaten at all points. He was forced to make a disgraceful peace, the terms of which, together with the discovery that John was among his enemies, broke his heart. He died at Chinon, July 6, 1189, and was buried at Fontevraud.

Henry's legislative activity, which was great and constant, deserves special notice. His aim was the consolidation of royal power by means of a centralized system of justice and administration. The Constitutions of Clarendon were an essential part of this scheme, designed to bring the clergy, as well as other classes of the nation, under the rule of law, and to prevent an ecclesiastical "imperium in imperio." Other enactments, as the Assize of Clarendon (1166), were intended to perfect the judicial system and to supersede the baronial by the royal courts. The system of recognition by jury took the place of trial by battle. The grand jury was organized for the presentation of criminals for trial. The jury system was further employed for the inquiry into the conduct of the sheriff (1170), and for the assessment of the Saladin tithe (1188). The enemies of the justices itinerant were, after repeated experiments, brought to something like perfection, and a high court of justice formed out of the Curia Regis, which was the origin of the Court of King's Bench. By the commutation of feudal service for scutage, and by the Assize of Arms (1181), which revived the national militia, Henry made himself independent of the baronage, and formed that alliance between king and people which was the surest basis of his power. Whatever may be said against his private character, the wisdom and steadiness with which he pursued these aims, and the permanency of the mark that he left upon the constitution, secure him the title of a great king.

HENRY III. (1207-1272), king of England, eldest son of John and Isabella, was born on October 1, 1207, and was just nine years old on his father's death. Ten days after that event he was crowned at Gloucester (October 28, 1216). His long reign falls into four periods,—that of the regency, ending with the fall of De Buig, that of government by favourites, which led to the Mad Parliament, the period of the Barons' War, and the short period between the close of the war and Henry's death. At his accession the whole country was in rebellion, and Louis with his Frenchmen held the east and south. In this crisis it was fortunate that the government fell into the hands of such a man as William Marshall, and that the pope gave him all the assistance in his power. The acceptance of the charter at once recalled many to their allegiance, and the defeat and retirement of Louis broke up the opposition. The charter was confirmed (1217) and order rapidly restored. The legate

Quale aided the earl marshal and Archbishop Langton in the work. On Marshall's death (1219) Pandulf took Quale's place, and asserted the papal authority in a way which obliged Langton to make a personal protest at Rome. Pandulf was recalled, and Hubert de Buig, the justiciar, ruled with Langton till the latter's death (1228), and alone afterwards. The influence of Peter des Roches, bishop of Winchester, the head of the foreign party and guardian of the king's person, was successfully resisted. Meanwhile a last outbreak of pure feudalism under Falkes de Breauté was put down, and the charter again issued in its final shape (1227). But the worst plague of the reign, the influence of foreign favourites, had already made itself felt, while another great evil, the financial exactions of Rome, was causing much discontent. An expedition to Poitou, opposed by De Buig, caused the first quarrel between him and the king. Shortly afterwards Peter des Roches returned from a temporary banishment, and gained such influence over Henry that he dismissed De Buig with insult and ingratitude (1232). From this point his real reign may be said to have begun.

The bad promise of his youth was amply redeemed in the events of the next twenty-six years. Under the influence of Peter des Roches, foreigners began to flock to the court, and even foreign mercenaries were introduced into England. Richard, earl marshal, who openly rebuked the king for this conduct, was outlawed, but other barons took up his cause, and collisions between them and the king's troops took place. Civil war appeared imminent, when Archbishop Edmund persuaded Henry to dismiss Peter des Roches, and the danger was avoided for the time (1234). But the king's partiality for foreigners was a constant source of discontent. In 1236 he married Eleanor of Provence. Two uncles of the queen, William, bishop of Valencia, and Peter of Savoy, came over with her, and were immediately placed in positions of honour and emolument. In 1238 Henry married his sister Eleanor to Simon de Montfort, a count which nearly produced an outbreak. Ricardus already contended in the Great Council, which in 1236 had declined "to change the laws of England," and supported the bishop of Chichester in his refusal to give up the great seal at the king's demand. Henry's personal extravagance caused him much embarrassment, and the extortions of the papal see pressed heavily on the church. In 1242 the barons refused to give the aid demanded by the king for another expedition to Poitou, and when they met again after his return, they joined with the clergy in a general protest against his misgovernment (1244). In order to remedy this state of things, it was proposed that the king's advisers should be chosen by the parliament, as it now began to be called, but Henry found means of evading the demand. If there be his brother Richard, earl of Cornwall, had been the leader of the opposition, but Simon de Montfort, earl of Leicester, was now becoming the centre of constitutional resistance. In 1246 the king's stepfather, the count of La Marche, died, and Henry's half-brother came to England, bringing with them a fresh crowd of hungry followers. The demands made upon the great cities, especially London, upon the Jews, and upon the clergy, to meet the expenses caused by the king's favourites, were constantly on the increase. Owing to the cessation of the office of justiciar since the fall of De Buig, the judicial system was falling into decay, and crime of all kinds was rampant. At the same time the pope engaged in his great struggle with Frederick II., regarded England as an "inexhaustible spring of wealth," and redoubled his demands. He won over most of the bishops by supporting them in their claim to respect the monastic houses in their dioceses, and the church, deprived of its natural head,—for Boniface, an uncle of the queen, was archbishop of Canterbury,—was disunited and helpless.

Grosseteste, bishop of Lincoln, was almost alone in his efforts to follow in the steps of Stephen Langton. He and De Montfort were at one in their desire for reform, but the nation was not yet ready. Two mistakes on the part of Henry brought matters to a crisis. He had conferred the government of Gascony on De Montfort in 1248, and the latter had reduced the province to obedience. But accusations made against him found ready audience with the king, who feared and disliked his brother-in-law. The result was a bitter quarrel (1252), which Henry followed up by superseding De Montfort in his government, and sending his eldest son Edward to take his place. This had the effect of throwing the real power for all into the hands of the national party. A little later an event occurred which forced that party to take active measures. The pope persuaded Henry to accept the kingdom of Sicily for his second son Edmund, and to bind himself to pay the expenses of his conquest, together with a large debt already incurred (1255). This important scheme was entered into without the knowledge of the parliament, and the nation suddenly found itself pledged to an undertaking which had purely dynastic or papal objects. The coalition of pope and king produced a corresponding union of the church and the baronage, and the troubles of the year 1257, Scotch and Welsh invasions, together with a failure of the harvest, united the nation against the government.

A parliament which met at Westminster (April 1258) forced Henry to promise reform, and elected a committee of twenty-four to act for the king till a complete scheme could be drawn up. On June 11th the assembly, called afterwards the Mad Parliament, met at Oxford. A council of fifteen, of whom two-thirds were on the baronial side, was appointed, who, together with twelve royal councillors of the "community," were to take charge of the government and meet in parliament thrice a year. Hugh Bigod was named justiciar, other offices were filled up, the castles were entrusted to Englishmen, and four knights were summoned from each county to declare grievances. These reforms, together with certain general enactments, went by the name of the Provisions of Oxford. The king's authority was completely superseded, and the rule of a baronial oligarchy established. Next year, owing to the demands of the knighthood, who felt themselves neglected, a further series of Provisions was issued. The Sicilian project was formally repudiated, and a final peace made with France, in which the claim on Normandy and other districts was renounced. But beyond this the baronial Government did nothing. The nation testified its disappointment, and a quarrel took place between the earls of Leicester and Gloucester which divided the baronial party. The king took advantage of this state of affairs, and in 1261 obtained abolition from the Provisions at the hands of the pope. He then fortified the Tower, deposed the baronial justiciar, and soon began to rule as before. In this crisis the baronial party made a bid for popular favour by summoning representatives of the counties to a parliament, but the reaction was for the time complete, and Henry had leisure to go to France in order to win over Louis IX. to his side. In 1263 hostilities broke out on the Welsh border, and the barons seized the opportunity to renew their attack on the king. After some months of desultory warfare, it was agreed to submit to the arbitration of Louis. That king, in the *Miroir des Amans*, decided in favour of Henry, and annulled the Provisions. Leicester at once appealed to arms. The battle of Lewes (May 14, 1264) was a complete victory for him, and put the king and his eldest son into his hands. For a time he was master of the country, but the party he headed was not that which had been dominant six years before, and Henry now had many adherents among the

greater barons. Nevertheless, for more than a year he remained practically a prisoner in the hands of De Montfort. At a parliament which met in June 1264, and at which knights of the shire were certainly present, a constitution was drawn up, which, while preserving to the king a high position as head of the executive, placed supreme power in the hands of the "community." Early next year, in a parliament to which members from the boroughs as well as from the counties were summoned, this constitution was confirmed, and Henry swore to observe it. In accordance with the settlement made at Lewes, Edward was now to be released. His father was already supposed to be at liberty, but in reality both he and Edward were kept in a castle. Edward's escape (May 1265) caused an immediate renewal of the war, and at the battle of Evesham (August 4, 1265) De Montfort was killed and Henry set free. Two years later the war was practically concluded by the capture of Kenilworth. Henry had little to do with the conduct of the war, and acquiesced in the arrangements made by his son for the pacification of the country. His triumph was, however, complete, and for the rest of his reign the kingdom was at peace. He died on November 16, 1272, leaving behind him the memory of one whose virtues were of the piestly kind, and whose worst vices were those of indulgence, ill-temper, and prodigality. As a subject he would have been harmless, and even perhaps respectable, as a king he was weak, hasty, imprudent, equally incapable in the position of a ruler, an administrator, or a general.

HENRY IV. (1366-1413), king of England, only son of John of Gaunt and Blanche, daughter of Henry, duke of Lancaster, was born in 1366. As the age of fifteen he married Mary Bohun, and in 1385 was made earl of Derby. Two years later he was one of the five lords appellants who impeached the earl of Suffolk and others, and took part in the proceedings of the Merciless Parliament. He acquiesced, however, in Richard's return to power, supported the king in his coup d'état of 1397, and became duke of Hereford. His quarrel with the duke of Norfolk led to his banishment shortly afterwards, and on his father's death, Richard deposed him the succession to his title and inheritance (1398). Next year he took advantage of Richard's absence in Ireland to reassert his rights. He landed in Yorkshire, took Bristol, and seized Richard (August 19) near Conway Castle. At a parliament which met on September 30th, he claimed the throne on the ground of his descent from Henry III., the right of conquest, and the necessity of reform. He was accepted by the parliament, Richard was forced to abdicate, and Henry was crowned (October 13, 1399). The list of his three claims gives the explanation of his policy. He had won the favour of the church by pledges in favour of orthodoxy, the circumstances of his accession and the difficulties of his government forced him to make concessions to the House of Commons, which made that body so a problem it did not again attain for more than two centuries. The first part of his reign was occupied with the suppression of the revolts, not only of the defeated party, but also of his own discontented adherents. These troubles were complicated by hostile relations with

France, Scotland, and Wales. Charles VI was inclined to take up the cause of his daughter Isabella, wife of Richard II, and on the death of the latter (February 1400) demanded her and her dowry back. The duke of Albany in Scotland was hostile to Henry, and Owen Glendower raised a national revolt in Wales. The first attempt at insurrection was made by the earls of Richard's party early in 1400, but their plans were discovered, and their forces crushed piecemeal. Most of the leaders fell victims to popular vengeance. A more serious rebellion was that of the Percies (1403), hitherto Henry's staunchest supporters. Hotspur and his father thought themselves ill requited for their services, and made common cause with Glendower and other malcontents. A junction of the northern army with the Welsh was prevented by the battle of Shrewsbury (July 21, 1403), in which Hotspur was killed. Northumberland submitted and was pardoned. But the danger was not over. The north was still in a state of ferment, the war in Wales went on, and a French fleet ravaged the southern coast with impunity. Henry's vigilance and activity were, however, equal to the task. A plot to carry off the young earl of March (January 1406) was foiled, and a fresh outbreak in the north was crushed. Scrope, archbishop of York, and Mowbray, earl marshal, who led the rebels, were taken and executed. The king had already got into his power the son of the duke of Albany, he now captured James, the heir apparent to the Scotch crown, as he was on his way to France, and the murder of the duke of Orleans removed his chief enemy in that country. Thus secured from danger abroad, he put down a final rebellion in the north, drove Glendower back into his mountains, and henceforward had no trouble at home (1408). The late crisis had, however, compelled him to make important concessions to the House of Commons. He promised (1407) to act solely by the advice of a council nominated with their approval, and submitted to the appropriation of his revenues and to other limitations. Throughout his reign he was hampered by want of money, and the regular evasions by parliament of the right to withhold supplies gave that body great control over his actions. He had saved the crown as the champion of orthodoxy. He had therefore to pay for ecclesiastical support by presenting Lollards against his will, while he did not dare to act upon the suggestion of the Commons that church property should be converted to purposes of state. Thus limited, his foreign policy was not energetic. He had enough to do at first to defend his coasts, and though he afterwards seized the opportunity afforded by civil war to invade France (1411), his efforts were in general confined to strengthening his dynasty by foreign marriages. In his later years he was a confirmed invalid, and had to entrust much power to his eldest son, with whom he was not always on the best of terms. He died on March 30, 1413, and was buried at Canterbury. A cautious, crafty, resolute man, naturally inclined to fair dealing and clemency, but on occasion unscrupulous and cruel, he was successful in the great enterprise of his life, and has the credit of seeing that the power he had usurped could only maintain itself by resting on a constitutional basis.

HENRY V (1387-1422), king of England, eldest son of Henry IV, and Mary Bohun, was born August 19, 1387. Early tried to arms, his first military effort was not successful, for at the age of thirteen he commanded an expedition to Wales which was defeated by Glendower. Three years later he was present at the battle of Shrewsbury, and in 1408 he revenged himself on Glendower by driving him back to Snowdon. At the same time his position in the council, at the head of which he appears after 1410, gave him experience in affairs, and proves the confidence already felt in his political ability. The stories of his youthful extravagance

and dissoluteness are unfounded, and, as the above facts show, improbable. Although his father appears to have been jealous of his popularity, he was practically at the head of affairs for some years before the death of Henry IV. Three weeks after that event he was crowned (April 9, 1413), and entered upon his inheritance with the good will of all classes of the nation. So unanimous was the support he met with in parliament that constitutional affairs cease to have any interest during his reign. In his ecclesiastical policy he followed the lines laid down in 1401, with much greater heartiness than his father, and shown in his persecution of heretics caused a conspiracy to surprise him and his brothers, which was discovered and put down with some severity (January 1414). St. John Old castle, the head of the Lollards, was condemned to be burnt, and though he escaped for the time, he was again taken in 1417, and put to death. Henry's orthodoxy brought him into connexion with the emperor Sigismund, then engaged in settling the affairs of the church at the council of Constance, and his assistance was very instrumental in the healing of the great schism. But the great work of his life was the conquest of France. It was with this object that he issued a kind of general amnesty on his accession, and appealed to the nation as a whole to support him. War was resolved on by parliament, and Henry laid claim to the French crown. This claim was afterwards reduced to one for all the districts which the English kings had ever held in France. Such claims as these, of course, precluded all negotiation. The expedition was not delayed by a conspiracy to carry off the earl of March, which was discovered before it was ripe, and on August 14, 1416, the English army landed at Havre. Havre was soon taken, but the English losses were so great that Henry resolved to retreat to Calais. On October 26th the French army that opposed his march was cut to pieces at Agincourt. The next two years were spent in preparations for continuing the war. In 1417 Henry again invaded France, took Rouen (1418) and with the assistance of the Burgundian party forced Charles VI to grant his demands. By the treaty of Troyes (1420) it was arranged that he should marry Catharine, take the government in hand at once, and succeed on Charles's death. This disgraceful treaty had, however, the effect of reviving the national party in France, and during Henry's absence in 1421 the English began to lose ground. He hurried back to France, but before he had had time to recover his position, he died at the castle of Vincennes, August 31, 1422. A great soldier, an able politician, a skilful diplomatist, a generous, pure, and high-minded man, he was one of the noblest and most popular of English kings. But these good qualities should not blind one to the fact that he was a religious persecutor, and that he plunged his country into an unjust and hopeless war.

HENRY VI (1421-1471), king of England, only son of Henry V and Catharine of France, was born on December 6, 1421, and was therefore only eight months old at his father's death. He can hardly be said ever to have reigned, for his long minority passed into another kind of tutelage, during which the influence of his wife and favourites prepared the way for civil war. Ten years of anarchy culminated in his dethronement, and ten years more of wandering and imprisonment fill the interval between that event and his death. The chief interest of the first thirty years of his life lies in watching the decay of English power in France, that of the last twenty in the fact that he was a civil war which resulted from the misgovernment of the preceding period. Throughout the English had lost some ground towards the end of Henry V's reign, their position, when the duke of Bedford undertook the task of continuing his brother's work, was very favourable. They held the north

and centre of France, while Burgundy held the eastern districts. The alliance with Duke Philip was strengthened by a marriage between his sister, Anne and the duke of Bedford. The Scotch king, James I, was released from captivity, in order that England might be relieved from danger on that side. Thus strengthened, Bedford was able to apply himself vigorously to the conquest of France, towards which the battle of Verneuil (1424) was an important step. But the English cause had already received its first great blow in the marriage of the duke of Gloucester with Jacqueline of Hainault, which destroyed the good understanding between Burgundy and England. Bedford for the time managed to stave off the quarrel, and after renewing his union with Burgundy, laid siege to Orleans, the key of southern France. The capture of the town seemed certain, when the appearance of Joan of Arc turned the scale. The relief of Orleans (1429) was followed by other French successes, and by the coronation of Charles VII at Rheims. The capture of Joan did little for England, for the spirit she had inspired survived her loss, and her death (May 1431) only navied the French to fresh efforts. It was in vain that Bedford had Henry crowned at Paris (December 17, 1431). The young king remained in France nearly two years (April 1430 to February 1432), but his presence did not turn the tide of French success. On the side of England the supply of men and money was falling short, while on that of France a new type of commander was coming to the front, who was not inclined to repeat the disastrous blunders of Crecy and Agincourt. The death of Bedford's wife (November 1432) broke the link that bound Burgundy to England, and negotiations for peace were set on foot. These culminated in a great congress at Amiens (July 1435), but the demands of the two countries were found incompatible, and the war was renewed. Bedford's death (September 14, 1435) finally destroyed all hope of recovery in France. Burgundy at once made peace with Charles VII, and the English commanders who succeeded Bedford were constantly defeated. Paris was retaken, Normandy overrun. Repeated efforts on the part of England led only to further exhaustion. Meanwhile negotiations for peace had been continued at intervals, and led in 1444 to a truce, during which Henry was married (April 22, 1445) to Margaret, daughter of René of Anjou. It was hoped that this marriage, together with the cession of Anjou and Maine, would lead to a permanent peace, and save Normandy and Guienne. But though Anjou and Maine were actually surrendered in 1448, the truce was broken next year, and before the end of 1450 the whole of Normandy was lost. In 1451 Guienne was reconquered by the French, and in 1453 Calais alone remained to England. This was practically an end.

Its conclusion coincides with the period when the two parties that divided England were just about to appeal to arms. The civil war was in great measure the result of the defects abroad, as those defects themselves were in part the consequence of discord at home. Quarrels between the chief members of the reigning house were the origin of its weakness, financial embarrassment, a divided foreign policy, and a feeble administration brought disgrace on the king and his advisers, family feuds and a long tale of mutual injuries added bitterness to political differences. Eventually an outburst of popular discontent kindled the train so long prepared, and the champion of order and good government began a struggle in which the original objects were soon lost sight of, and which ended only with the death of the king whose innocent imbecility had caused the disorder. To check the rivalry of Henry's uncle, the duke of Gloucester, and his great-uncle, Cardinal Beaufort, was beyond the power of the council. Bedford alone could appease the quarrel, and Bedford's presence in England

meant disaster in France. The quarrel between them and their adherents was complicated by the existence of the Lollards, and the question of peace or war. In both matters Gloucester, as persecutor of the Lollards and head of the war-party, appeals to have taken the more popular side. The coronation of the young king at Westminster (November 6, 1429) put a formal end to the regency of Bedford and Gloucester, but not to the intrigues of the latter. The House of Commons was unable to interfere with any effect, the Lords were mostly engaged on one side or the other. The death of Bedford removed the only guarantee of peace, and Gloucester attacked Beaufort with more violence than ever after his brother's death. In the midst of these troubles Henry VI came of age (1442). Had he been a great statesman, he would have found an almost hopeless task before him. But, unfit as he felt himself to be, he naturally shrank from politics, and was much more intent on completing his foundations at Eton and Cambridge than on healing the disorders of his country. The work of government was left mainly in the hands of Cardinal Beaufort and the earl of Suffolk, who did their best to secure peace with France. On the other side the dukes of Gloucester and York headed the opposition, and took up the cry of reform, with the object of infusing vigour into the government at home and abroad. Suffolk, however, won a great victory in the truce with France (1444), and through the young queen Margaret, whose marriage was chiefly due to his exertions, he obtained complete influence over the king. The suspicious death of Gloucester (1447), followed in six weeks by the death of his rival Beaufort, together with the appointment of York to the governorship of Ireland, left Suffolk master of the situation. But such a position could not be long maintained in the face of the odium which always attaches to a favourite, and the complete failure of his foreign policy brought about his fall (1450). The king in vain attempted to save him, and by so doing shared his unpopularity, while the partial concessions he made to the demands of the rebels under Jack Cade only postponed the inevitable outbreak. The duke of York now made himself the mouth-piece of popular discontent. When the final loss of France had exhausted the country's patience, and the birth of an heir to the throne had destroyed his hope of the succession, he took advantage of Henry's mental derangement to claim the protectorate (1453). It was granted him early next year, but in 1455 the king recovered his senses, and York was deprived of power. Unable to endure this he marched on London, and on May 22, 1455, the Wars of the Roses began in the battle of St Albans. The effect of the battle was to bring the queen to the front as the leader of the royalists, and to make the quarrel between her and York irreconcilable. During the four years of uneasy quiet which followed the first collision, Henry tried hard to keep the peace. But all his efforts were vain. When the struggle broke out anew, and the Yorkists won the battle of Northampton, he was forced to consent to an arrangement by which his son was excluded from the succession and York recognized as heir to the kingdom (1460). The settlement was of short duration. York himself lost his life at Wakefield, but his son seized the crown and was acknowledged king (March 4, 1461). The battle of Towton brought the struggle to an end for ten years, and the capture of Henry in 1465 seemed to secure Edward IV. on the throne. Five years later a sudden revolution hushed him from it, and restored the wretched prisoner for a while to liberty, but the battle of Barnet destroyed his hopes again. He had time to know that his son had died at Tewkesbury, that his wife was a prisoner, and that his cause was finally lost, before death released him from captivity on May 21, 1471. Gentle, pure, and generous, full of good intentions, enthu-

provided means for the popularity of his successor, and to Henry VIII fell the easy and generous role of squandering the treasure which his father had amassed. Nor was this the only respect in which the young Henry entered on the fruit of other men's labours. In the Wars of the Roses, and by the policy of Edward IV and Henry VII, the old feudal nobility had been brought very low. When nothing more was to be feared from that quarter, it was Henry VIII's easy task to gather round him the broken remnants, to attach them to his person, and to make them the ready instruments of his will, in short, to convert the representatives of a haughty feudal bourgeoisie into subservient courtiers. In character the young Henry was a king according to the people's heart, even in his faults he was exceptionally fortunate. He was handsome, frank, extravagant, of vast muscular strength, accomplished in all the manly exercises of the time and in the new learning, he was vain, thirsting for popularity, eager to retrieve the old renown of England, the enemy of France, and dreamt always of renewing the conquests of the Henrys and Edwards. It is not surprising that Henry excited the highest expectations in all classes of his subjects, for his varied character offered an attractive side to all of them. The men of the new learning were charmed by his love of letters. Ecclesiastics saw with pleasure his punctual performance of the duties of religion. All good men were delighted with the excellence and purity of his private life. Statesmen were struck by his capacity for business, his gaiety and frankness captivated the courtiers, the prospect of French conquest inspired the warlike and the ambitious. From the description of Henry by the Venetian ambassador, Gustamini, in 1510, we can easily perceive what impression he must have made on England at his accession.—"His Majesty is twenty-nine years old, and extremely handsome. Nature could not have done more for him. He is much handsomer than any other sovereign of Christendom,—a good deal handsomer than the king of France,—very fair, and his whole frame admirably proportioned. On hearing that Francis I wore a red beard, he allowed his own to grow, and as it is reddish, he has now got a beard that looks like gold. He is very accomplished, a good musician, composes well, is a most capital horseman, a fine jouster, speaks good French, Latin, and Spanish, is very religious, hears three masses daily when he hunts, and sometimes five on other days. He hears the office every day in the queen's chamber,—that is to say, vesper and compline. He is very fond of hunting, and never takes his diversion without tiring eight or ten horses, which he causes to be stationed beforehand along the line of country he means to take, and when one is tired he mounts another, and before he gets home forty are all exhausted. He is extremely fond of tennis, at which game it is the prettiest thing in the world to see him play, his fair skin glowing through a shirt of the finest texture." When we take all these facts into consideration, when we remember also that ere long he had raised England from a third-rate position to a level with the greatest powers of Europe, and that for twenty years nothing serious occurred to break the harmony of his reign, we cannot be surprised that Henry was a most popular king.

The reign of Henry falls naturally into two periods, separated by the question of the divorce. During the first period Henry is the splendid and jovial king at home, abroad a figure of the first magnitude in the wars and international diplomacies of the time. Both in home and foreign affairs, but particularly the latter, Wolsey was the right hand man of the king, ready, as occasion served, either to transact the whole business of the government, or to be the humble instrument of the king, when the royal hand did actually interfere. In point of fact Henry always was master, and took a keen interest in business. The events

of the first period were concerned chiefly with the foreign wars. At home, with the exception of the execution of Empson and Dudley, the instruments of his father's extortion, who suffered, however, on a tumbled-up charge of treason, nothing important occurred. There were Christmas revels, May festivals, tilting matches, in which Henry always shone victorious, and in which he squandered the treasures of his father. But the serious endeavours of the time were directed abroad, Henry joined his relatives Ferdinand and Maximilian in a league against France. Though Henry took a personal share in the campaign in France of 1513, and won the easy Battle of Spurs, and though Surrey, his general, gained the great victory of Marston, no substantial result was attained by the war. Henry was duped and then abandoned by his allies. When he was undeceived, he made peace (1514) with France, which was cemented by the marriage of his youthful sister Mary to the old and worn-out Louis XII. Soon after, when Louis was succeeded by Francis I (1515), and Charles V entered on the government of his hereditary dominions (1516), the three monarchs who figure so conspicuously as the contemporaries of the Reformation, and whose doings constitute so much of the history of the 16th century, found themselves face to face. With these two and with the successive popes Henry had to do during the rest of his life. Their relations at first were chivalrous and even friendly. Henry never had any chance of success in his conquests for the imperial crown. When it fell to Charles, it made him beyond a doubt the first monarch of the age, his success placed him in open rivalry to France, but to Henry, fortunate again, it gave the desirable prospect of being courted by the two rivals, and even of acting as arbiter in their disputes. Henry, however, descended from this lofty position to engage in quarrels which had no concern with the true interests of England. The chimes of French conquest again fascinated him and his people, so that when the false chivalry of the Cloth of Gold had degenerated into war, Henry took the side of Charles. In the campaign of 1525 the English forces advanced to within eleven leagues of Paris, but the way led to no durable and satisfactory results so far as Henry was concerned. The people grew sick of the heavy contributions they were called upon to make, and threatened revolt. After the battle of Pavia (1525), where the French were completely overthrown and their king made prisoner by the armies of Charles, the policy of Henry was completely disturbed. Till that event it had been clear enough. The commercial interests of the country, which were bound up with the Flemish dominions of Charles, the ambition of Wolsey, who founded his hope of the papal crown on the good-will of the emperor, the hereditary enmities and warlike instincts of the people, as well as the inclination of the king, concurred conveniently in requiring the imperial alliance. But now France was down, and the balance of power, already a working conception in politics, was destroyed, while Charles in his triumph ignored the claims of Henry, and had more than once disappointed the ambition of Wolsey. Under these circumstances English policy was forced out of its old groove, and an alliance was made with France. In a short time, moreover, interests and passions of a far more momentous nature emerged. The dilatory politics of Henry's early career were to be superseded by occupations of a tragically earnest nature. Adventurous enterprises abroad were to give place to real interests at home, and the jovial young king was to be transformed into the stern, self-willed, and often cruel revolutionary. The serious and important part of Henry's life therefore is still to come, but before leaving the earlier period it is well to remark that it lasted twenty years, or more than half of his reign, that during these years Henry was popular in the highest degree, and especially that he

had gratified the national pride of his subjects by restoring England to a leading position in Europe. This should not be forgotten during the troubled and more questionable events that were to follow.

The year 1538 may justly be fixed as the turning point of Henry's life. By that time the divorce had become a national and even a European question, and Henry had decisively committed himself to the course which was to result in the separation from Rome. It is not clear when the plan of a divorce began to take shape in Henry's mind, it was the slow result of a variety of causes which were not dear to the king himself. We know, however, that Anne Boleyn returned to the court of England in 1529, that she made quite a sensation there as soon as she appeared, and that among other admirers, married and unmarried, Henry soon expressed a decided preference for her. On the other hand, he seems to have been alienated from Catherine long ere the question of divorce became public, if we may trust a statement of his own, he had abstained from her bed since 1524, and his coldness for her increased with his love for Anne. That his scruples regarding his marriage awoke about the same time was certainly a very convenient coincidence. The danger, however, of a disputed succession in the absence of male heirs was a real one. The situation probably justified such an extraordinary measure as a divorce, though we must recollect that the saving of a second family, rival to Mary the daughter of Catherine, might precipitate the very crisis which men feared. Still we must admit on the whole that the national interest and the inclination of Henry coincided, and that concern for his kingdom probably had a large part in the mixed motives which urged him to seek a divorce.

When the demand for a divorce was first formally laid before the pope in 1527, no one anticipated that it would encounter so many difficulties. The great opponent of it was Charles V., who loyally supported his aunt, and who, as the event proved, had the pope entirely in his power. But for the emperor, Clement would soon have arranged everything to the satisfaction of the English court. As it was, he sought safety in delay. Thus he declined giving any decisive answer himself, and when he delegated the case to Wolsey and Campeggio, he managed still further to defer the question and then to revoke it to Rome (1529). By that time Henry's patience was exhausted. As early as 1528, and as if sure of a speedy decision in their favour, the king and Anne were living familiarly together under the same roof. Their disappointment was natural, and Henry soon began to take more active measures. He appealed from the pope to the universities. Notwithstanding his life-long services Wolsey was discredited, because he was supposed not to have been sufficiently earnest about the divorce. The same year (1529) a parliament was called, which proved to be the ready auxiliary of the king in his new policy. This parliament, which sat at intervals from 1529 to 1536, had little independent or substantive power, it was made up largely of the nominees and creatures of the court, and seldom moved but at the royal initiative. Still it was well that the old forms should be recognized in the great changes that were coming, and significant that the strong-willed Tudor felt it safe to have the nation at his back. The changes themselves were gradual, and were by no means disagreeable to the advanced and influential part of the nation. Only a very small minority had any sympathy with the Lutheran movement, but many wished to see the church reformed, to have her power curtailed, and that England should take up a more independent attitude towards the pope. Under these circumstances Henry found it easy to carry the majority, especially the active and progressive part, of the nation with him. In no case was the parliament of 1529 conscious of its destiny, what it con-

templated was not a revolution but only some necessary reform, it, as well as Henry, would have been astonished to hear that they were working on the side of Luther. Yet the parliament soon proceeded to take some very decisive steps. In 1529 the probate duties and mortuaries (or burial fees) exacted by the church were curtailed, the clergy were prohibited from following secular employments, residence was enforced, and pluralities forbidden. In 1531 the clergy were laid under the charge of praemunire, which they bought off by the payment of £118,000, and the acknowledgment that the king was supreme head of the church. In 1532 the abuses of "Benefit of Clergy" were reformed, annates abolished conditionally, and the independent legislative power given up by convocation. Soon after the king took a step which precipitated the crisis, he married Anne Boleyn, an event which was quickly followed by the publication in Flanders of a threat of excommunication from Rome. After this the Act of Appeals was passed, forbidding appeals from the English ecclesiastical courts to Rome, and Cranmer, in a court at Dunstable, declared the marriage with Catherine null and void. In the following year (1534) the papal authority in England was annulled, and by the Act of Supremacy Henry was declared supreme head of the English Church. The next step was a sad one, but it convinced the world that the king was in earnest. Sir Thomas More and Thomas bishop of Winchester, the noblest champions of the old faith, two of the best and noblest Englishmen of the time, were executed for refusing to accept the Supremacy Act (1535). Such an event produced a deep sensation in Europe, but it was decisive, when the pope drew up the Bull of Deposition in 1536, which, however, was not published till 1538, the rupture with Rome was complete. In the same year (1536) the first Articles of religion, ten in number, were drawn up, in effect they were a great simplification of the old creed, though they gave little encouragement to Lutheranism. At the same time the Act for the dissolution of the smaller monasteries, which was based upon the report of a commission of inquiry, was passed, being the final important measure of the first Reformation parliament. With such events as the abolition of the papal power in England and the dissolution of the monasteries modern England begins, they inaugurate a fundamental change in the national policy and in the structure and habits of society. While the purpose, real or ostensible, of Henry had been merely to marry a younger woman and provide for the succession, he had effected the greatest revolution which England has undergone.

Henry had indeed succeeded in the task to which he had applied himself nine years before, but the enemies he had used were formidable, and he was destined to many a bitter disappointment. He had excited the hostility of the pope and the emperor, worst of all, he had seriously hurt the feelings and prejudices of a large class of his subjects. The danger of foreign invasion was greatly increased by the discontent both in the north and west of England, where the love of use and wont in the church and in the national habits was strongest. The death of Catherine had indeed greatly relieved him, as it made reconciliation with the emperor practicable, and deprived the English opposition of a common centre. The rising in Ireland was suppressed without much difficulty, but the discontent in the north which broke out in the Pilgrimage of Grace was a formidable danger (1536). It was averted more by skilful statesmanship on Henry's part than by open show of force. The opposition in the west was quelled in the land by the execution of its leaders, the marquess of Exeter and Lord Montague (1538). These measures of the king and of his minister Cromwell sometimes appeared cruel and unjustifiable, but they kept the country united, Charles was con-

vinced of the futility of an invasion, and the thunderbolts of the pope fell harmless to the ground. In all this crisis, when a wrong step or the appearance of vacillation might have occasioned a religious war, in which the conservatism at home would have been seconded by the aims of Spain, the energy and the commanding sagacity of Henry did more than ought also to save the country. To him the prince is chiefly due that this great revolution was comparatively free from blood and havoc.

Henry had dethroned the emperor and the pope, and he had suppressed the conservative Catholic discontent at home with a high hand, but he was never disposed to be a Protestant. Instead of following the lead of the advanced Reformers he impressed upon the English Church his own moderate and substantially Catholic theology. At thirty he had defended the seven sacraments against Luther, he was thirty-six when he took up the question of divorce, and he was forty-one when he severed the pope had hardened into alienation and hostility. All his life he was orthodox from conviction as well as from traditional assent. Such a man could not be a revolutionary in theology. He repudiated with a firm hand all excess in innovation, showing equal aversion to the iconoclastic mob and to iconoclastic preachers. The bill of the Six Articles, passed in the same year that saw the final dissolution of the monastic system of England, was the most remarkable exemplification of this spirit of Henry. It also proves that innovation in theology was a new thing to the mass of the English nation, and its penalties too clearly illustrate the fact that religion was not considered an individual and private matter, but a national interest, the violation of which was a capital offence. It is to the honour of Henry that the victims of the Bloody Statute were so few. Five hundred arrests were made by the angry Catholic party in a single fortnight after the passing of the bill, but the king interposed in time, and only twenty-eight suffered under the statute during the whole reign.

In the meantime Henry had been less fortunate in the matrimonial scheme which had been the occasion of all the changes and dangers we have noted. A few months after the death of Catherine, Anne Boleyn was sent to the scaffold. Anne may have been guilty of the crimes laid to her charge, but Henry himself had taught her to cast aside all feminine reserve and self-respect, and his fickle heart had been captivated by another, long before the disclosure which was the ground of his divorce. Henry married his new love, Jane Seymour, the day after the execution of Anne (1536). The birth of Edward in the following year gratified the king's desire for a male heir, but the early death of Jane left him again without a queen. After an interval of more than two years Cromwell undertook to procure a suitable wife at the Protestant courts of Germany, but his ruin was not less complete than that of his patron Wolsey on a similar occasion ten years before. Anne of Cleves found no favour in the king's eyes, she was divorced and pensioned off, while the enemies of Cromwell succeeded in sending her to the scaffold. Anne's place was occupied by Catherine Howard, tall, shrewd, really guilty, was also executed (1542). For his sixth and last queen Henry married (1543) Catherine Parr, who proved a patient wife and an excellent nurse. During the last few years of Henry's reign home affairs and the question of the religious revolution ceased to be the exclusive subject of interest. England and the neighbouring powers were constrained to acquiesce for the time being in Henry's arrangement of things. Even the emperor cultivated his alliance. His foreign politics ended very much as they began—with a war against Scotland and France. The former arose out of certain border quarrels, the Scots were beaten at Solway Moss, but defeated an English force at Anorum Moor. After the death of James V

Henry's course was to arrange a marriage of the infant queen of Scots with his own son Edward. The plan failed through Henry's self-will, and Scotland was ravaged to no purpose. The war with France (1513-46) was equally fruitless. Its chief feature was a threatened invasion by a formidable French fleet, which for some time was master of the Channel.

At home the most important point of interest was the struggle between the two factions, Protestant and Conservative, which had now for some years confronted each other—Norfolk and Bishop Gardiner of Winchester being the leaders of the latter, while the queen, Cromwell, and the earl of Hertford, uncle of young Edward, were at the head of the former. Cromwell had already fallen under the machinations of the Conservative party. Cromwell and even the queen were not quite safe from its attacks. The heads of that party now suffered at the close of the reign. Surrey was executed, and Norfolk was saved only by the death of the king. The effect of such measures was to make the prospects of Edward secure by confirming the power of his uncle Hertford.

Henry was anxious to arrange affairs for the accession of his son, as he felt his own life was waning away. Though only in his fifty-sixth year he was unwieldy with disease and incapacity, and he required to be wheeled from room to room, an ailment in the leg had troubled him for many years. In this as in so many other respects the contrast between the beginning and end of his career is striking: the young athlete is transformed into a helpless invalid, the joviality, the enthusiasm, and the unanimity of his earlier reign gave place to a long period of gloom and contention, repressed only by the savage and impetuous hand of the king. He died on the 28th of January 1547.

The character of Henry has long been a stumbling-block to historians, and will always be a puzzle to such as classify mankind under the two heads of good and bad, without recognising the intermediate gradations to which the vast majority belong. To many it is all the more inexplicable, because the contrast between his youth and declining manhood is so apparently complete. Yet it was a perfectly consistent, though a mixed character, and the later phases of it are only a natural development of the earlier. He was always strong-willed to excess, capricious, and fickle, with the sensitive part of his nature predominating. In his youth his base tendencies were controlled by his love of popularity, his regard for his excellent wife, his own sense of duty, and the vigorous animal spirits which found congenial play in physical exercise and in foreign war. In his maturer years he was more self-reliant and therefore less dependent on popularity, after losing his regard for Catherine he fell into baser companionship, as his health began to fail, his boisterous spirits declined. Worst of all, his constitutional fickleness took the form of disloyalty to his successive wives, and to his friends and ministers. In the time of Henry there was no acuter man than Sir Thomas More. His verdict may be accepted as final on this aspect of the king's character. In the height of his favour with the king, after walking an hour with him in the garden at Chelsea, the king holding his arm about his neck, More confessed that he had "no cause to be proud thereof, for if my head would win him a castle in France it should not fail to go." Such may have been the repulsive side of Henry. Much more important, however, than the consideration of his personal character is the question as to the nature and tendency of the historic work in which he took the initiative. Was that the outcome merely of misguided self-will concealing itself under the guise of duty, or was it the true and durable expression of the claims and aspirations of the time? The passions of Henry had certainly too much to do with it, the work he did was, like his character, mixed with baser elements. But the best answer to such

a question is to be found in the modern history of England. That history in its progressive spirit, in its gradual approximation to a sounder and better state of society, and in its liberal openness to the influence of truth, is only the continuation and development of the work of Henry. In his rupture with the pope, in his abolition of an idle and antiquated monasticism, and in his endeavour to establish a purified and simplified Catholicism as the permanent creed of England, he was fighting on the side of truth and light and progress. The English Reformation was too much alloyed with baser elements to serve as an ideal example of a great historic change, yet it succeeded better than any other in appropriating the good both of the old and the new, in avoiding a violent rupture with the past, in keeping the nation unanimous, and in escaping those fatal religious wars which desolated Europe for nearly a century and in Germany delayed the progress of civilization for a century more. This desirable consummation was due first of all to Henry, whose sagacity and unflinching resolution baffled the enemies of reform both at home and abroad, who repressed the hasty movements of either fanatical extreme in England, and who, with his real reverence for the teaching of the past, yet a hearty contempt for its abuses. He was no hero, no ideal man of king, he shared fully in the consciousness and indecision of the age, he was fickle in his personal attachments, and did not shrink from destroying those who crossed his plans; but he had a real and lofty sense of his duty as a king, he had a true insight into the men and things he had to deal with, and helped to lead the country into a new era.

German
kings
and em-
perors

HENRY I. (876-936), German king, was born in 876 in Saxony, of which his father, Otto, was duke. He distinguished himself in early youth by the courage and energy with which he warred against the Slavonic tribes to the east of his native duchy. Otto, who died in 912, appointed Henry his successor, not only as duke of Saxony but as lord of Thuringia and part of Franconia. Conrad I., stimulated by certain ecclesiastical advisers whom Henry's independent bearing towards the church had deeply offended, raised the claims of the young duke, but he was ultimately left in possession of all the lands his father had ruled. After Conrad's death Henry was chosen king by the Franconian and Saxon nobles, and he had not much difficulty in securing the acquiescence of the rest of Germany. For some years Lotharinga or Lorraine had held an uncertain position between the kingdoms of the East and the West Franks, as Germany and France were then called, but at this time Duke Gisbert, who was an old friend of Henry, quarrelled with Charles the Simple, and transferred his allegiance to the German king. For eight centuries afterwards Lorraine remained a part of Germany. From the time of Louis the Child, Germany had been riven, and who had the advantage of fighting on horseback while the Germans resented them on foot. In 922 an Hungarian chief was captured, and his people were compelled to purchase his release by agreeing to a nine years' truce, on condition that Henry should during this time pay an annual tribute. In the northern districts the Germans had hitherto lived for the most part in small villages or on separate settlements, after

the fashion described in the *Germania* of Tacitus. Henry, perceiving that so long as they continued thus exposed to attack they could never be safe, began the building of cities throughout Saxony and Thuringia, and in the other duchies, his example was extensively followed. He also trained his vassals to meet the enemy on horseback, thus giving a strong impetus to the movement which resulted in the institutions of chivalry. When his arrangements were complete he tried his new force in a contest with the Danes and with some Slavonic tribes, whom he utterly defeated. In 933 the Hungarians demonstrated as usual the tribute which had till then been punctually paid, and when it was refused invaded Thuringia with a great army and Henry twice defeated them, and they were so overwhelmed by this misfortune that they did not enter Germany for some years, and were never again seen in the northern duchies. Having thus broken the power of all the chief enemies of his country, Henry took precautions for the future by establishing the marches of Schleswig, of Meissen, and perhaps of Brandenburg. In his home government he acted with great caution and judgment. The dukes had become so powerful that there was some danger of their altogether overshadowing the throne. Instead of directly meeting this peril by forcing them into submission, as was afterwards done by his son Otto, he attached them to his interests by confirming them in many of their rights and by acting as a mediator in their disputes. Towards the close of his life his position was so secure that he resolved to go to Rome and claim the imperial crown. In the midst of his preparations he died in 936 at Memleben, and was buried in St Peter's church at Quedlinburg. He was one of the wisest and most energetic of the German kings, and through his encouragement of municipal life, and his powerful defence of Germany against her foreign enemies, his reign marks an epoch of the highest importance in early medieval history. By his first wife, Harburg, he had a son Thankmar, who gave Otto I., his successor, much trouble. After she was put away he married Mathilda, the daughter of a Saxon count, and the gentle and noble character of this lady, who was universally beloved, was of essential service to him in his rule.

See Watz, *Jahrbücher des Deutschen Reichs unter Heinrich I* (Berlin, 1857, 2d ed., 1863).

HENRY II. (972-1024), Holy Roman emperor, was born in 972. He was the son of Henry the Wrangler, duke of Bavaria, a grandson of King Henry I. In 995 he succeeded to the duchy of Bavaria, and six years afterwards went to Rome with the young emperor Otto III, to whom he rendered important services. When Otto III. died, Henry, as the chief surviving representative of the house of Saxony, took possession of the insignia of the empire, and was crowned German king at Mainz on the 7th of June 1002. Encouraged by disturbances in Germany, a rebellious party of nobles in northern Italy raised Margrave Hilduin of Ivrea to the throne of Lombardy, but Henry advanced against them, and, like his immediate predecessors, made himself master of the non-crown. His most determined enemy during the greater part of his reign was Boleslaus II of Poland. This ambitious and strong-willed prince annexed Bohemia, and during the king's absence in Italy broke into Lusitania and Meissen. Henry hurried back, defeated Boleslaus in 1005, and granted Bohemia in fief to Jaromir, son of the previous duke. Boleslaus, however, continued the war, which was not ended till 1018, when Henry was obliged to conclude peace on terms that were much more favourable to the Poles than his would have voluntarily granted. In the midst of this struggle he had to make war on Adalbert, his wife's brother, who seized the archbishopric of Trier, and was protected in his claim by another brother of the

empress, the duke of Bavaria. Both were overcome and deprived of their dignities, although Bavaria was ultimately restored to the older of the two brothers. Henry also put down rebellions in Flanders and Meissen, and he concluded an important treaty with Rudolf III. of Burgundy, whereby after Rudolf's death the country was to be united to Germany. In 1013 Henry went for the second time to Italy, while Harolduin had again ascended himself to the throne. The usurper was displaced, and in 1014 Henry was crowned emperor at Rome by Benedict VIII., whom he had confirmed in the papal see in opposition to the antipope Gregory. At the request of Benedict the emperor returned to Italy in 1022 in order to drive back the Greeks, who were steadily pressing northwards. In this enterprise he associated himself with the Normans, who thus became one of the most important factors in the political life of Italy. Henry's health, which was always feeble, rapidly declined after this third visit to his southern dominions, and in 1024 he died. He was canonized by Pope Eugenius III., and at a later time his wife, Cunigunda, was also ranked among the saints. It was natural that they should be thus honored, not only because of their fervent piety, but because the church has rarely had a more splendid benefactor than Henry II., whose ruling policy was to balance the power of the great nobles by increasing that of the spiritual princes. He also founded the bishopric of Bamberg, which was placed under the immediate jurisdiction of the pope, and to which he left by will all his treasures and his magnificent alodial possessions.

See Henry, *Jahrbücher des Deutschen Reichs unter Heinrich II.* (Berlin, 1862-75).

HENRY III. (1017-1056), Holy Roman emperor, was the son of Conrad II., the founder of the Franconian dynasty. He was born in 1017, and his father, anxious to make the succession secure and to strengthen the authority of the crown, caused him to be elected German king in 1026, creating him in 1027 duke of Bavaria, and in 1038 duke of Swabia and king of Burgundy. He became the reigning sovereign of Germany in 1039, at the age of twenty-two. Of an upright and resolute temper, he soon made his power felt both in church and state. The policy he pursued was that which had been followed by Otto I. during the early part of his reign, that is, he granted as many of the duchies as possible either to members of his own family or to vassals on whose loyalty he could rely. Duke Gottfried of Lower Lorraine, who laid claim to Upper Lorraine also, was the only prince who gave him serious trouble, and even this impetuous opponent could not effectually resist the great emperor. Henry was as distinguished in his wars as in his home government. Duke Bretislav of Bohemia, who gave signs of aspiring to an independent position, invaded Poland, plundered its chief cities, and as a mark of his triumph carried away the body of St. Adalbert from Gnesen to Prague. Henry proceeded against him in 1041, and forced him to appear in the following year at Ratibon in penitent's garb, and to accept Bohemia in fief of the German crown. Having settled this difficulty, he began in 1043 a series of campaigns in Hungary, where for the first time he asserted the supremacy of Germany. In Italy he was equally successful, not only maintaining his right to the Lombard crown, but establishing supremacy over the Normans in Apulia and Calabria. At this time the moral condition of the church was regarded with regret and concern by every serious nature, and Henry, who was of a deeply religious tendency, associated himself heartily with the movement for reform which proceeded from Cluny. At a council of prelates in Suiza in 1046, he caused the rival popes, Benedict IX., Sylvester II., and Gregory VI., to be deposed, and raised to the papal see, as Clement II., Stutiger, bishop

of Bamberg. Three other German bishops, one after the other, were appointed to the same position, and as all of them were devoted men and energetic administrators, they did much to purify the ecclesiastical system of Europe. During that rule the papacy was held in strict subjection to the empire, but the very earnestness with which Henry applied himself to the task of making the church worthy of its mission created grave dangers for the state, since it was improbable that a pope of proud and independent spirit would be content with a subordinate position. The magnitude of the peril soon revealed itself when Hildebrand became pope during the reign of Henry IV., Henry III's son and successor. Henry died in the prime of life in 1056 at Bamberg.

See Hildebrand, *Jahrbücher des Deutschen Reichs unter Heinrich III.* (Leipzig, 1874).

HENRY IV. (1056-1106), Holy Roman emperor, son of Henry III., was born in 1056, and crowned German king at the age of four during his father's lifetime. After the death of Henry III. in 1056, the government was undertaken by the empress Agnes, the young king's mother. Henry III.'s vigorous rule, while it had secured the prosperity of the nation as a whole, had created later discontent among the great nobles, and immediately after his death they began to make attempts to recover some portion of the independence he had taken from them. Agnes, who was of too refined a temperament to contend with them, sought to win their support by important concessions, and the evil effects of a feeble central authority were soon felt in every part of Germany. At last, in 1063, Anno, archbishop of Cologne, succeeded in gaining possession of the king by entering him on board a boat on the Rhine. Agnes then resigned her position, and Anno ruled in her stead. He was a harsh, bigoted, and despotic prelate, and created Henry's later hatred by the sternness of his discipline. In Adalbert, archbishop of Bremen, who was of an exactly opposite disposition—gay, worldly, and good-humoured,—Anno had an influential rival. This prelate was at first estranged with some share in the training of Henry, but ultimately completely gained his affections and became his sole guardian. In his fifteenth year Henry was declared, in accordance with the Ripuarian Code, to have reached his majority, but the royal authority was really exercised by Adalbert, who aroused the jealousy of the princes both by his splendid style of living and by his opposition to their usurped powers. At a diet held in Tribur he was compelled to yield the first place once more to Anno. Trained under these diverse influences Henry became passionate and wilful, but he was endowed with considerable intellectual gifts, and when thoroughly aroused could pursue an object with unquenchable ardour. In order, if possible, to check the excesses of his private life Anno caused him to marry Beatrix, the daughter of the margrave of Silesia, to whom he had for some time been betrothed. At first he regarded her with strong dislike, but after she had borne him a son in 1071 she succeeded in gaining his affections, and was afterwards his most trusted friend and companion.

Henry's reign was one of the most troubled in German history. His chief anxieties began in consequence of Otto of Nordheim, duke of Bavaria, being charged with an intention of murdering him. Otto was declared to have forfeited his titles, and his lands were seized and overrun. Supported by Duke Magnus of Saxony he rebelled, but both princes were quickly subdued. A new rebellion was organized by Otto of Nordheim, who suddenly, at the head of 60,000 men, appeared before the Harzburg, a strong Saxon fortress in which Henry resided. He escaped, but he was looked upon so coldly by the princes that he found it expedient to yield nearly all the demands of his enemies.

An opportunity of revenge was, however, created for him by the violence of a body of peasants, who destroyed a chapel connected with the Habsburg and violated the graves of the king's brother and infant son. He had then no difficulty in obtaining an imperial army, and after defeating the rebels at Hohenburg in 1076, he imposed on them his own terms, and seemed to be on the point of asserting the ascendancy which had been exercised by Henry III.

Meanwhile Hildebrand had become pope as Gregory VII., and had already indicated his design of making the papacy supreme over all earthly authorities. Henry appealed to him to degrade those prelates who had associated themselves with the rebels. Instead of repoussing favourably to the appeal, Gregory called upon the king to answer to certain charges preferred against him by his subjects. Failing to realize how much power the papacy had acquired through the reforms effected by his father, Henry summoned a council of German prelates at Worms in 1076, and declared the pope deposed. The reply was a sentence of excommunication. Henry's adherents so rapidly fell away that a reconciliation with the pope was soon perceived to be absolutely necessary. Escaping from his enemies he crossed the Alps in the depth of winter, accompanied only by his wife and child and by a few faithful attendants. The nobles of Lombardy were not unwilling to take up his cause, but he preferred to hurry forward to the castle of Canossa, where Gregory was residing with his friend the Countess Matilda. There occurred the famous scene in which Henry, the highest of secular potentates, stood for three days in the courtyard of the castle, clad in the shirt of a penitent, and entreating to be admitted to the pope's presence. No historical incident has more profoundly impressed the imagination of the Western world. It marked the highest point reached by papal authority, and presents a vivid picture of the awe inspired during the Middle Ages by the supernatural powers supposed to be wielded by the church.

The ban was removed, nevertheless the German princes elected Duke Rudolf of Swabia as their king, and they were soon openly supported by the pope, who resented Henry's persistent opposition to his great scheme for the deliverance of the clergy from the system of feudal investiture. Henry renewed his sentence of deposition against Gregory, and raised Guibert, archbishop of Ravenna, to the papacy as Clement III. After the death of the anti-king Rudolf in 1080 he went to uphold his rights in Italy, and in 1084 he gained possession of Rome, while Clement III. crowned him emperor. In Germany Count Hermann of Luxembourg had been chosen as successor to Rudolf, but in 1085 he defeated Henry near Wunsburg, but in 1087 he voluntarily resigned his position, and soon afterwards died. A third anti-king, Margrave Eckbert of Meissen, also died in 1089, and had Henry had no enemies outside his native kingdom these would then have been peace. But Victor III. and Urban II., the successors of Gregory VII. (who died in 1085), continued to oppose him, and in 1090 he was obliged to proceed to Italy for the third time to support Clement III., his own antipope. Whilst engaged in this struggle he learned that his son Conrad had been induced by the papal party to rebel against him. Stunned by this unexpected blow, the tired emperor withdrew in disgust to a remote fortress, where he remained inactive for several years. In 1096 he recovered his energy, returned to Germany, and by timely concessions managed to overcome the opposition of his leading enemies. A diet at Mainz decided that Conrad had forfeited his right to the throne, and his brother Henry was proclaimed the emperor's successor. Pope Urban II., the antipope Clement III., and Conrad, all died within two years, and Henry had reason to hope that

he would be able to end his life in quiet. But Paschal II., pursuing the policy of his predecessors, once more excommunicated the emperor, who was driven to despair by the fact of his son Henry putting himself at the head of the pope's supporters. The aged monarch, deceived by false promises, fell into his hands, and was detained as a prisoner. He ultimately fled to Lidge, where he might still have been able to bring an army together, but in 1106 he was relieved from his heavy cares by death. The bishop of Lidge buried him with a splendor becoming his position, but his enemies carried the body to Spire, where it was laid in an unconsecrated chapel, and it was not properly interred until, after a delay of five years, he was delivered from the ban of excommunication.

Henry holds an honorable position in history because, notwithstanding many personal faults, he resisted the excessive pretensions both of the papacy and of the ambitious feudal lords of Germany. His was unable, however, to make good his claims. Centuries passed before the secular power of the Roman see was seriously weakened, and amid the confused struggles of the time the princes obtained a secure possession of rights which they had formerly held by an uncertain tenure.

See Geschichte der Deutschen Kaiserzeit (3d ed., vol. 1, part. I, Darmstadt, 1869), Floth, Henry IV. and sein Zeitalter (3 vols., Stuttgart, 1859), Mühlwirth, Die Bisse Kaiser Heinrichs IV. an Canossa vor dem Papste Gregor VII. (2d ed., Leipzig, 1876).

HENRY V. (1081-1125), Holy Roman emperor, son of Henry IV., was born in 1081. In 1098, his elder brother Conrad having forfeited his right to the throne by rebellion, he was appointed his father's successor. Six years after wards he himself rebelled against the emperor, towards whom he played the part of a thorough traitor. The papal party, with which he allied himself, took for granted that when he mounted the throne church and state would be infinitely reconciled, but then hopes were disappointed. The main point for which Henry IV. had contended was the right of investing the bishops with ring and staff. When Henry V. succeeded him in 1106, Pope Paschal II. demanded that this right should be given up, but he replied that he could not resign powers which had been exercised by his predecessors, and the loss of which would imply that the ecclesiastical lands of Germany would be removed from secular control. In 1110 he entered Italy at the head of 30,000 men. Alarmed by this display of force, Paschal withdrew his claims, and a day was appointed for the coronation of Henry as emperor. The opposition of the Roman prelates made it impossible for the pope to proceed with the ceremony, whereupon he and his cardinals were made prisoners. Paschal then formally recognized the right of investiture, and Henry received the imperial crown. When the Germans had reconquered the Alps Paschal renounced the treaty he had concluded, and the emperor was excommunicated. As many of the princes were pleased to find this opportunity of rebelling, Germany again became the scene of confused contests like those which had brought misery upon it during Henry IV.'s long reign. In 1116 the emperor went a second time to Italy and drove Paschal from Rome, and after Paschal's death he caused Gregory VIII. to be appointed pope. The extreme papal party, however, selected Gelasius II., who renewed the sentence of excommunication against Henry. The latter returned to Germany in 1119, and at a diet in Tribur succeeded in allaying the hostility of the more important among his enemies. Pope Calixtus II., who succeeded Gelasius in 1119, now found it necessary to offer a compromise, and the controversy between the empire and the papacy was for the time closed by the concordat of Worms, which was concluded in 1122. By this treaty it was agreed that at every election of a prelate the emperor should have the right

of being present, either in person or through a representative, and that the chosen bishop, before being consecrated, should receive his lands and secular authority in fief of the crown. So far the advantage rested with the emperor, but the papacy gained by being recognized as a power which had the right of negotiating with the empire on equal terms, and by the acknowledgment of the claim of the church to nominate its own rulers. Notwithstanding this settlement Germany did not long enjoy peace, for a number of petty wars broke out which Henry was not strong enough to quell. He died at Nuremberg in 1125, and with him was extinguished the Franconian dynasty.

See Giesbrecht, *Geschichte der Deutschen Kaiser* (3d ed., vol. II, pt. 2, Bismarck, 1868), Gervais, *Geschichte Deutschlands unter den Regierungen Heinrichs V. und Lothars* (Leipzig, 1841-42), Kolbe, *Die Kaiser Friedrich I. von Mainz und Heinrich IV.* (Hildesheim, 1876).

HENRY VI. (1135-1197), Holy Roman emperor, the son of Frederick I., was born in 1135, and received the German crown in 1159. When his father started for Palestine at the head of the third crusade, Henry was made imperial viceroy, and he succeeded to the throne after the news of his father's sudden death reached Germany in 1190. He shared the intellectual culture of his time, and was distinguished for the splendour of his political schemes, but he was of a stern disposition, and in order to attain his ends was sometimes guilty of horrible cruelty. Henry the Lion, who had been banished to England by Frederick I., returned to Germany after the departure of the latter for the Holy Land. Henry treated him, but on becoming the reigning sovereign he concluded peace, and hastened to Rome, where he was crowned emperor in 1191. Through his wife Constantia he had a right to the throne of Sicily, but the Sicilian nobles had made Count Tancred, an illegitimate son of Constantia's brother, king. After receiving the imperial crown Henry advanced against Tancred, and the whole of southern Italy except Naples was quickly in his possession. Before Naples his army was struck by pestilence, and he was forced to return to Germany. There he suppressed various private wars, and compelled Henry the Lion to acknowledge his supremacy. The great ransom which he received from Richard I. of England enabled him to fit out a fine army, and with this he descended upon Italy in 1194, and without much difficulty conquered the Sicilian kingdom. Tancred was dead, but he had left a number of relatives, who were so barbarously treated that the people were seared with terror, and not even a sentence of excommunication which the pope pronounced against Henry could induce any one to express dissatisfaction with his rule. On his return to Germany it was easy for him, with the prestige he had now acquired, to enforce submission, and so great was his authority that, in 1196, he made attempts to secure that the crown should be declared hereditary in his family. He might have succeeded had he lived some years longer, but in 1197 he died at Messina.

Before his death he was engaged in checking disorder which had arisen during his absence in Sicily, and he even obliged the Byzantine emperor Alexius to pay him tribute. See Toebe, *Lebensgeschichte des Deutschen Königs Heinrich VI.* (Leipzig, 1867), Mücke, *Kaiser Heinrich VI.* (Bamberg, 1876).

HENRY VII. (1282-1313), Holy Roman emperor, was born in 1282. He was the son of Henry II., count of Luxembourg, and was elected king in 1308, seven months after the murder of Albert I. He owed his election partly to the fact that he was comparatively unimportant, which led the electors to suppose that under him the powers of the princes would be exposed to no great danger. When he came to the throne Bohemia was subject to Henry of Carinthia, whom the people extremely disliked. The king at once displaced him and enriched his own family by granting Bohemia, at the request of the Bohemians themselves, to his son John, whose claims were rendered

secure by his marriage with Elizabeth, the daughter of Wenceslaus II. For some time the German king had sought the imperial crown, but Henry, who was of an imaginative temperament, could not forget the splendid dignities to which the wearers of the crown of Germany were entitled. He therefore resolved to revive the traditions which had begun to die out, and with a view to this result did what he could to compose the differences of the nobles and to gain their allegiance. At this time there were signs of rapid progress among the cities, and had a strong king devoted himself to their interests, he might have established his throne on a solid basis. Unfortunately the easiest way in which Henry could obtain immediate power for his plans in Italy was to ally himself with the princes against the cities, and this was in most instances the course which he adopted. His visit to Italy was looked forward to with eagerness by the Ghibellines, whose hopes were expressed in words of glowing eloquence by Dante. He held aloof at first from both the great parties in the state, and was in consequence liked by neither. In 1312 he was crowned emperor in Rome, having previously received the iron crown in Milan. But while he was in Rome, Robert of Naples was there also with a strong army, and in order to obtain adequate support it was necessary for Henry to declare himself on the side of the Ghibellines. He then resolved to conquer Naples, but while advancing on this expedition he died at Buonconvento, on the 24th of August 1313. It was generally believed at the time that he had been poisoned by a Dominican monk, but this is not proved by satisfactory evidence.

See Dümmler, *Acta Henrici VII.* (Berlin, 1840-41), and *Geschichte des Deutschen Kaiserthums im 14ten Jahrhundert* (Berlin, 1841), Thomm, *Die Konigswahl des Grafen Heinrich von Lothringen im Jahre 1308* (Strassburg, 1875), Polmann, *Der Kaiser Heinrich VII.* (Nuremberg, 1875).

HENRY I. (1005-1060), king of France, son of King Knute of Robert and Constance of Aquitaine, and grandson of Hugh Capet, came to the throne in 1031. On his accession his mother, who favoured her youngest son Robert, allied herself with the chief feudal nobles, and drove Henry to take refuge at the court of Duke Robert II. of Normandy. With the duke's help he soon broke up her league. Constance died in 1052, and Henry, by granting him the duchy of Burgundy, secured the goodwill of Robert's brother, who thus became head of the first house of Burgundy. After the death of Robert "the Devil," Henry, who had first supported William the Bastard, in 1053 and 1054, tried to weaken the power of the Normans. Leaguering himself with the count of Anjou, and calling his brother Eudes into the field, he invaded Normandy from Evreux. When, however, Eudes had been defeated at Mortemay, Henry drew back in haste, and left the Normans to themselves. In 1059 he had his eldest son Philip crowned as joint-king, and died in 1060. He was an active prince, with his sword mainly in the scabbard, being little more than a great feudal chief, who enjoyed the feudal pastime of petty war. Henry's acts and character did little to strengthen the monarchy in its relations with its feudal neighbours. His political horizon was very narrow. The Normans were independent of him, with their frontier barely twenty-five miles west of Paris, to the south his authority was really bounded by the Loire, in the east the count of Champagne was little more than nominally his subject. Henry's first wife (if indeed she was more than affianced to him) Mand, daughter (or niece) of Conrad the Salic, died childless; his second, Anne, daughter of Jaroslav, grand-duke of Russia, bore him two sons, Philip his successor, and Hugh, count of Vermandois.

See Rohault-Lolme, *Chronique, Chon Andegavensis, Histoire de Henri I.*, *Epist. Dudoensis*, Dom Bouquet, *Recueil*, tom. xi.

HENRY II. (1519-1559), king of France, the second son of Francis I. and Claude, succeeded to the throne in 1547. When only three years old he was sent by his father, with his brother the dauphin Francis, as a hostage to England in 1550, where they returned after the conclusion of the peace of Cambrai in 1559. Henry was too young to have carried away any abiding impressions, yet throughout his life his character, dress, and bearing were far more Spanish than French. In 1533 his father married him to Catherine de' Medici, from which match, as he said, Francis hoped to gain great advantage, even though it might be somewhat of a misalliance. He did not then think that the dauphin would die so soon, and Catherine thereby became queen of France. Italian manners and politics entered with her into France, and long affected the history and fortunes of the country. Henry gathered round him a court which contrasted strongly with that of his father Francis, with all his grave faults and selfishness, had fostered learning, had treated his people kindly, and had wisely checked even the Reformers. But Henry, under the influence of Diana of Poitiers, headed the strict Catholic movement, the escape of the learned from Paris to Geneva at his accession showed that not merely Huguenot doctrines but Renaissance studies were in part of this court underwent immediate change. The effect was almost disastrous, and men whose France had disliked or banished returned. Catherine de' Medici was at court, but it ceased to be gay and bright, men must be grave and severe, and even then vices. At first Diana of Poitiers and the great old soldier Anna of Montmorency swayed the king, later, the two brothers Francis, duke of Guise, and Charles, cardinal of Lorraine, rose to power, with the marshal St. André, everything was done and given through one or other of these men. Catherine de' Medici was yet completely in the background.

The final union of Brittany with France marks the opening year of the reign. In 1548 Henry won a great diplomatic triumph over the ministers of Edward VI of England, by getting possession of Mary queen of Scots, then only six years old, he had her educated in France, and eventually married to his son the dauphin Francis. In 1519 he appeared in Paris for the first time, and marked his presence by a great banishing of Calvinists, and soon after he banished Lefevre Brague, which had been the cause of the French Revolution. In 1522, after a successful campaign, he made the English Government, then extremely weak, cede Boulogne, and leery entered the place in May 1550.

The time was now approaching when he would enter into contact with him, and permanently advance the borders of his kingdom, while he infused a great blow on the emperor. Though early in his reign he had dealt with the German Protestants, and with the Ottoman power, he had taken no active steps, nor the league of German princes, headed by Maurice of Saxony, offered an opportunity not to be missed. Henry made a compact with the Swiss and Turks, and concluded a secret treaty (September 3, 1550) with the German princes, in 1552, by the league of Chambord he undertook to seize the three bishoprics—Metz, Verdun, and Toul. And so while Maurice drove the emperor from Innsbruck, Henry sent Montmorency into Lorraine. The bishoprics were won almost without a blow, and Henry was acknowledged as "avenger of Germanic liberty." An attempt on Strasbourg failed. After the siege of Metz by Charles V in the winter of 1552-53, this district, French-speaking, though feudally under the empire, remained in

French hands,—Metz till 1870, Toul and Verdun to this day

In 1566 Henry IV, supporting the anti-Spanish policy of the "Theatine" pope, Paul IV, again made war with Spain. Francis of Guise was sent early in 1567 into Italy to oppose the duke of Alva. Anne of Montmoutency went to the northern frontier, Gaspard of Coligny, who commanded in Picardy, was ordered to begin hostilities. These led to the disastrous battle of St. Quentin, in which the French were defeated. In the fall of 1568, the duke of Alva, chief bulwark of France to the north. Francis of Guise, recalled in haste from Italy, redressed the balance at the expense of England by the capture of Calais (July 1568), and the triumph of the house of Guise seemed complete when Mary Stewart was married to the dauphin in the same year, their niece, with her claims on the Scottish and English crowns, would now ascend the throne of France. The defeat of the French at St. Quentin, the desire of Montmoutency to escape from captivity, the wish of the high Catholics to have leisure to evaluate policy, the sympathy of Philip with that aim, the accession of Elizabeth of England—all these things made peace nces sary, and the treaty of Cateau Cambresis (April 1559) closed the war. As a sequel to the peace high feast was held at Paris to celebrate the marriage of Henry's two daughters, in a tournament he received his death-wound from the captain of his Scottish guards, Montgommery. So ended Henry II, his last day's reign. Elizabeth, his daughter, was crowned, and his mark was left on all but forgotten in the stormy days which followed. By Catherine de' Medici he had ten children, three of whom succeeded to the throne,—Francis II, Charles IX, and Henry III. The legislation of his reign was slight, he reduced the number of seignories of state to four, and arranged three functions afresh, he issued an edict in behalf of a better courage, reserved to himself the exclusive sale of salt, and permitted the foundation of the university of Rouen. In 1575 was laid the first stone of the new church established at Paris, the church which was quickly followed by others. He saw the close of the struggle between the crowns of Spain and France.

HENRY III (1551-1589), king of France, third son of Henry II and Catherine de' Medici, succeeded to the throne of France in 1574. In his youth, as duke of Anjou, he was warmly attached to the Huguenot opinions, as we learn from his sister Margaret of Navarre, but his unstable character soon gave way before his mother's will, and both Henry and Margaret remained as choice ornaments to the Catholic court. Henry won two brilliant victories at Jarnac and Moncontour, but, as duke of Anjou, he attracted the eyes of the Polish nobles, who elected him then king in 1573. He went to Warsaw, but, on the death of his brother Charles IX in 1574, came back to France and assumed the crown. He returned to a wretched kingdom, torn with civil war. Now began that "age of favourites" which has made his career a byword with his mother, ever balancing between parties, first favoured the favourites, then went with the Huguenot chief. In those days the famous League was organized (see FRANCE, vol. II, p. 562), and Henry devoted himself to his love life. He took but a feeble part in the wars, and, as duke of Anjou, he was, in 1584, the death of his younger brother, Charles, duke of Anjou, made Henry of Navarre next heir to the throne, and excited to the utmost the fierce passions of the Guises and the League. The

Parisian development of the League under the "sixteen" (1585), with its devotion to Henry, duke of Guise, and its determination to evulse the heretic of Navarre, to depose the wavering Henry III, and to make Cardinal Bourbon king,—thus, as well as the menacing attitude of Philip II of Spain, forced Henry III to draw towards his distant cousin Henry of Navarre. And so he was driven to desperation by the commanding position assumed by the house of Guise, and in 1588 Henry of Guise and his brother the cardinal were assassinated by his orders. Henry III now found himself powerless, early in 1589 he again joined Henry of Navarre, and with him laid siege to Paris. There he was murdered by one Jacques Clement, a priest. With Henry III ended the direct line of the house of Valois. In his young days he had been enthusiastic for learning and the new religious opinions, as he grew older he grew worse, and the last of the sons of Catherine de' Medici was perhaps the most debauched of the kings who hitherto had sat on the throne of France.

St. *Almanach de Tournes, Almanach de Verdille, Almanach de Cheltenham, Almanach de Valenciennes, Almanach de la Rue de la Poire, Thomas (Dr. Thon), Illust. des emp. Labr. O. X. F., Journal de l'Éclair, Almanach de la Ligue, Art de regner, les ducs, les rois, etc.*

HENRY IV (1553-1610), king of France, was born in the castle of Pau in 1553, being son of Antony of Bourbon, king of Navarre and duke of Vendôme, and Jeanne of Albret. By his father he was tenth in descent from Saint Louis, and only a very distant cousin to his predecessor, Henry III. His mother, a grand and noble lady, brought him up as a Calvinist. His education was rough and hard, and he was without any quality of character which so marked his life, his military training was under the great captain, Gaspard of Coligny. In 1571 he was wedded to the daughter of Catherine de' Medici, Margaret of Valois, and on his mother's death in 1573 he became king of Navarre.

The massacre of St Bartholomew found him in Paris, but his life was spared on his making a profession of Catholicism, which he had to do in order to succeed in clearing his head of the Huguenots, and by his dashing bravery kept life in their dispersed forces. No man was better fitted for such work, he had all the qualities of a guerrilla leader, though he was not a great general. His success at Coutras (1587) and the joyousness and generosity of his character endeared him to his followers, while it secured the respect even of his opponents. After the death of Henry III he was recognized as king of France by only a portion of the army then besieging Paris (August 4, 1589), the Catholics "Politiques" in the army stood aloof and disbanded, the Huguenots formed the only sound nucleus of his power. At Agonez (1590) and Ivry (1590) he brilliantly defeated the League, and resumed the siege of Paris, Alexander of Parma, however, prevented him from taking Rouen (1592), much less could he take Paris. Finding affairs hard, and desiring to be a king and not a guerrilla-captain, in 1593 Henry allowed himself to be converted to Catholicism. By this step he struck a deadly blow at the League and made powerless the intrigues of Philip II. For between the fanatical Catholics on one side and the Huguenots on the other lay the great bulk of Frenchmen, the "Politique" party had become more and more powerful, until at length it was felt to be the true national party. The only thing which kept it from Henry was the difference of faith, that barrier removed, all France at once joyfully accepted him as king. The League became almost a foreign body, the Huguenots gloomily accepted his triumph, bought, as they held, at cost of principle. After the battle of Fontaine-Francaise in 1595

the Spanish and League were driven out of Burgundy, and the recovery of Amiens from the Spaniards in 1596 secured Picardy and the northern frontier. The *Satire Menippique*, published in 1593 and 1594, had already condemned the League as hooligans of the Spanish king, and in April 1598 by the edict of Nantes Henry assumed their position to his old Huguenot followers, while by the peace of Vervins (May 1598) he ended the Spanish war, and took from the League its last source of strength.

After 1598 the energies of Henry IV were given to the restoration of his country, which in nearly forty years of civil war had suffered terribly, the organizing genius of Maximilian of Bethune, duke of Sully, restored the finances, agriculture, manufactures, and commerce made marvellous advances. Henry also upheld the authority of France, in 1601 he acquired Bresee, Dugey, and Valomey from Savoy. He supported the Netherlands against Spain, and he was preparing a great army, which, in combination with the Dutch under Maurice of Nassau, was to interfere in the tangled Cleves-Juliers question, when he was assassinated by Ravaillac on the 14th of May 1610. For his character see *FRANCE*, vol. ix, p. 510.

Henry IV left no children by his first wife Margaret of Valois, by his second, Marie de' Medici, he had three sons and three daughters,—Louis, who succeeded him as Louis XIII, a child who died in 1611, Gaston, duke of Orleans, the youngest of the race, Elizabeth, wife of Philip IV king of Spain, Christiana, wife of Victor Amadeus, duke of Savoy, and lastly Henriette Marie, queen of England, spouse of Charles I. He also left behind him several natural children, of whom the most celebrated was Louis, duke of Vendôme, son of the famous Gabrielle d'Estées.

HENRY I (1512-1580), king of Portugal, born at Oporto Lisbon, January 31, 1512, was the third son of Emanuel the Fortunate, was destined for the church, and in 1533 was raised to the archiepiscopal see of Braga. In 1542 he received the cardinal's hat, and in 1578 when he was called to succeed his grandnephew Sebastian on the throne, he held the archbishoprics of Lisbon and Coimbra as well as that of Braga, in addition to the wealthy abbacy of Alcobaz. As an ecclesiastic he was pious, pure, simple in his mode of life, charitable, and a learned and liberal patron of letters, but as a sovereign he proved weak, timid, and incapable. On his death in 1580 after a brief reign of seventeen months the male line of the royal family which traced its descent from Henry, first count of Portugal (c. 1100), came to an end, and all attempts to fix the succession during his lifetime having ungenerously failed, Portugal became an easy prey to Philip II of Spain.

HENRY I (c. 1207-1217), king of Castile, son of King Alfonso "the Noble," by Eleanor, daughter of Charles Henry II of England, succeeded his father in 1214, and was killed by the falling of a tile in 1217, after a reign of only two years and nine months. He was succeeded by Ferdinand III, son of his sister Beatrix.

HENRY II (1333-1370), king of Castile, surnamed *el Bastardo* or *de la Merced*, was one of the six illegitimate sons of King Alfonso "the Avenger," and consequently half-brother to Pedro the Cruel, who legally succeeded to the throne of Castile in 1350. His mother was Leonora

de Gusman. The extraordinary series of cold-blooded murders which earned for Pedro his unenviable surname encouraged Henry, then known as count of Trastámara, to lead repeated rebellions, in which, with the aid of the French under Du Guesclin, and in spite of the opposition of the English under the Black Prince, he was ultimately successful in 1369. He immediately proceeded to direct his arms against the most formidable of his numerous enemies, King Ferdinand of Portugal, and by four campaigns, during the last of which he forced his way to the very gates of Lisbon (March 1373), succeeded in establishing a favourable peace. At the same time he entered into a treaty with the king of Navarre, which was entered, however, for only three years, in 1375 friendly relations with the king of Aragon were formed, which were cemented by the marriage of the daughter of the latter, to Don Juan of Castile. The reign of Henry II, which was devoted rather to defensive than to aggressive warfare, was not marked by any of the usual exploits against the Moors, but it is distinguished in the annals of Castile by some noteworthy improvements in legislation and reforms in the administration of justice, sanctioned in the cortes of Toro in 1369 and 1372, and Spanish historians also mention with special pride the defeat of the English by the Spanish fleet at Rochelle in 1372. Henry died, of poison it is supposed, on May 30, 1379, and was succeeded by his son John (Juan) I.

HENRY III (1379-1406), king of Castile, surnamed *el Doliente* (the sickly), succeeded his father John I. in 1390, when only eleven years of age. During his minority, the question of the regency not having been very clearly settled by his father, the kingdom was in a constant state of disturbance, bordering upon civil war, unable to satisfy the rival claims of Don Fadrique, Don Alonso, and the archbishop of Toledo. Henry at last resolved, minor as he was, to take the reins of government entirely into his own hands (1393). By energetic measures he succeeded within two years in quelling the turbulence of his nobles, in establishing his own popularity with the body of the people, and thus in effecting the pacification of his kingdom. The only foreign war during the reign was that with Portugal, which terminated in the peace of 1399, a great expedition against the kingdom of Granada, for which extensive preparations had been made, and for which large grants from the cortes held in Toledo in 1406 had been obtained, was brought to an abrupt termination by the death of Henry at that city on December 25 of the same year. It was during the reign that the sovereignty of the Canary Islands was assumed by Castile, and an interesting indication of at least a widening interest in foreign affairs was afforded by the mission of a solemn embassy to Tunis in 1401. Henry III was succeeded by John II, his eldest son by Catherine of Lancaster, whom he had married in 1393. See Davila, *Historia de la Vida y Hechos del Rey Don Henrique Tercero de Castilla* (1638).

HENRY IV (1425-1475), king of Castile, surnamed *el Impotente* (the impotent) and sometimes *el Liberal* (the spendthrift), the eldest son of John II, by his first wife Maria of Aragon, was born at Valladolid on January 6, 1425. As prince of Asturias he took a prominent and generally an unpopular part in most of the disturbances of his father's reign, in 1445 a pitched battle between the king and the prince was prevented only at the last moment by the intervention of the clergy and some of the nobles, and peace was not finally secured until 1450 when Pope Nicholas V issued his bull of excommunication against all those in the peninsula who, by perplexing the affairs of the sovereign, were disloyally helping the cause of the infidels. In 1440 Henry had in accordance with a treaty signed in 1436 been

united to Blanche of Aragon, but this marriage, which had not been happy and which had given cause to many scandalous reports, he dissolved in 1433 shortly before his accession to the throne on his father's death in July of that year. He began his reign with a great show of energy against the Moors, but the boldness of his intentions contrasted strangely with the feebleness of his execution, and the unsatisfactory character of the results attained tended greatly to bring to a head the discontent which his indolent inattention to home affairs, his reckless extravagance, and the disorders of his private life had not failed to create. In 1465 occurred at Avila the extraordinary scene, so often described, of the king's deposition in favour of his brother Alphonso, this was followed in 1468, shortly after Alphonso's death, by the election of his sister Isabella, who, however, declined to accept the proffered crown. In the same year Henry was forced to repudiate his wife Joanna of Portugal and to disinherit his daughter Juana (Isabella) whom he had unsuccessfully attempted to put forward as also his, and thus the succession became fixed in favour of Isabella, who was married to Ferdinand of Aragon in the following year. Henry died at Madrid on December 12, 1474.

For the events of the reign of Henry IV the contemporary authorities are Alonso de Palencia and Diego Hurtado de Castille, each of whom has left a *Crónica del Rey Don Henrique Quarto*, the best and at the same time the most accessible modern English account to be found in Pichon's *History of the Reign of Ferdinand and Isabella*, parts 1, chapters iii and iv.

HENRY I (c. 1210-1274), king of Navarre, surnamed *le Gros*, third count of Champagne, was the youngest son of Theobald I of Navarre by Margaret of Flanders, and succeeded his oldest brother Theobald II in December 1270. His proclamation at Pamplona, however, did not occur till March of the following year, and his coronation was delayed until May 1273. After a brief reign, characterised it is said by dignity and talent, he died in July 1274, unmarried, according to the generally received accounts, with his own fat. In him the male line of the counts of Champagne, kings of Navarre, became extinct. He was succeeded by his only legitimate child Joanna, born in 1270, by whose marriage to Philip le Bel in 1281 the crown of Navarre became for a time united to that of France.

HENRY II (1603-1655), or Henri d'Albret, titular king of Navarre, born at Sanguesa in April 1603, was the eldest son of Jean d'Albret by Catherine of Navarre, and on the death of the latter in exile in June 1610 succeeded his parents in all their claims against Ferdinand the Catholic, assuming under the protection of Francis I of France the title of king of Navarre. After the intellectual conference at Noyon (1616) and at Montpellier 1618, an active effort was made in 1621 to establish him in the *de facto* sovereignty, but the French troops which, under André de Béarn, had saved the country were ultimately expelled by the Spanish victory, the duke of Najera. Henry, who along with Francis was taken prisoner at the battle of Pavia (1525) but afterwards contrived to escape, married Margaret, the only sister of the latter, in 1526, and by her became the father of Jeanne d'Albret, the mother of Henry IV of France. He died at Pau on May 25, 1555.

HENRY III of Navarre. See HENRY IV of France.
HENRY, PRINCE (1394-1460), of Portugal, surnamed "the Navigator," to whose enlightened foresight and perseverance the human race is indebted for the maritime discovery, within one century, of more than half the globe, was born at Oporto, on the 4th of March 1394. His father was João I., under whose reign Portugal first began to recover from her subjugation by the Moors, and to assume a prominent position among the nations of Europe, his mother was Philippa, daughter of John of Gaunt. Prince Henry and his elder brothers, Duarte and Pedro, were sent

out in 1415 on an expedition against the important Moorish city of Ceuta, which, after much hard fighting, they succeeded in taking in one day. All the princes distinguished themselves at the siege, but Prince Henry so pre-eminently that, but for his own intestates, his father would have knighted him in precedence of his brothers. His renown after this became so high that he was invited severally by the pope, the emperor, and the kings of Castile (Juan II) and England (Henry V) to take the command of their respective armies. The prince, however, had set his mind on other and larger plans, involving more than the hope of reaching India by the south point of Africa. To this end he had several encouragements: the geographical position of Portugal was in his favour, the large revenues of the order of Christ, of which he was grand-master, provided him with means, and he had contrived to gather important information from the Moors with regard to the coast of Guinea and the populous nations of the interior of Africa. Accordingly in 1418-19 he took up his abode on the extreme south-western point of Europe, the promontory of Sagres, in Algarve, of which kingdom he was made governor in perpetuity, with the purpose of devoting himself to the study of astronomy and mathematics, and to the instruction and encouragement of the expeditions which he proposed to send forth. There he erected an observatory, the first set up in Portugal, and at great expense procured the services of one Mestre Jacome from Majorca, a man very skilful in the art of navigation and in the making of maps and instruments, to instruct the Portuguese officers in those sciences. An account has already been given of his principal explorations in the article GEOGRAPHY, vol. x p 180 (q v). At first his efforts seemed to be crowned with little success, and his various expeditions called down upon him much obloquy from the nobles, who complained of such an amount of useless expenditure, but on the prince's intreaties fell harmless. The king died in 1433, and the troubles which followed occupied Prince Henry until 1440. In the following year Cape Blanco was reached, and in 1443 intercourse was established with negro states in Senegal and Gambia. In 1442-3 Henry VI of England conferred on the prince the riband of the order of the garter. In 1444-5 was discovered the river Senegal, Cape Verde, Cape St Anne, Cabo dos Mastos, and the Rio Grande. During the later years of his life Gomez and others made important voyages of discovery. Prince Henry's services (see vol. x p 180). He died November 13, 1460, in his town on Cape St Vincent, and was buried in the church of St Mary in Lagos, but a year later his body was removed to the superb convent of Batalha. His great-nephew, King Dom Manuel, had a statue of him placed over the central column of the side gate of the church of Belem. On July 24, 1840, a monument was erected to him at Sagres at the instance of the Marquis de S. da Bandeira.

The glory attaching to the name of Prince Henry does not rest merely on the achievements effected during his own lifetime, but on the stupendous subsequent results of his maritime discovery, to which his genius and perseverance had laid the primary foundation. The voracious loyalty continued what the prince had begun. The millions issued effected within a century from the founding of Cape Bonaville in 1482 formed one unbroken chain of discovery, which originated in the genius and the efforts of one man. They were the stupendous issue of a great thought and of indomitable perseverance, in spite of twelve years of exile, famine and distressing ridicule. As Mr Major, in his *Life of Prince Henry*, has justly said, "Had that famine and that ridicule produced on Prince Henry the effect which they ordinarily produce on other men, it is impossible to say what delays would have occurred before these mighty events would have been realized - for it must be borne in mind that the aid, not only of his own sailors, but of surrounding nations, owed its impulse to this pertinacity of purpose in him."

HENRY THE LION (1129-1195), duke of Saxony and Bavaria, son of Henry the Proud, was born in 1129. After the death in 1139 of his father, who had been deprived of his possessions by Conrad III, the bravery and energy of his mother Gertrude and his grandmother Richenza seemed to him the dukedom of Saxony. Shortly after coming of age he at the diet of Frankfurt in 1147 demanded also the restoration of Bavaria, but was refused, upon which, along with his uncle Welf VI, he made an unsuccessful attempt to seize it by force of arms. In 1154 he, however, received from Frederick I the formal recognition of his claims to its possession, and in 1156 Henry Jasomirgott was compelled to deliver it up to him. Besides distinguishing himself in the wars of Frederick in Italy, Henry now devoted his energies to establishing his power in his own dominions, both by conquest and by encouraging agriculture and trade. He extended the boundaries of Saxony beyond the Elbe by successful battles against the Slavs, founded Munich in Bavaria, colonized Mecklenburg and Holstein, and fostered the growth of Hamburg and Lubeck. His ambitious projects and his arrogant bearing awakened, however, the hostility of several of the secular and ecclesiastical potentates, who in 1166 concluded a league against him at Meissenburg, and a stubborn contest of two years' duration ensued, which was finally ended by Frederick in 1169 deciding at the council of Bamberg in Henry's favour. In February 1168 Henry, having previously divorced Clementia of Zähringen, married Mathilda, daughter of Henry II of England, and, elated by such an influential alliance and by the increasing resources of his dominions, he shortly after his return from a pilgrimage to the Holy Land in 1172 began to manifest a tendency to treat the emperor with coldness and to revive the traditional rivalry of his race with the Hohenstaufens. He took no part in the Italian expedition of 1174, and in 1176 his sudden denunciation of Frederick in the crisis of his struggle with the Lombard cities resulted in the disaster at Legnano. On Frederick's return from Italy in 1177 Henry was summoned to appear before him at the diet of Worms, and declining to do so he was placed under the ban of the empire, and his lands were divided among other princes. For more than a year he endeavoured to resist the execution of the imperial decree, but he found it necessary at last, in November 1181, to give in his submission to Frederick, who, on condition that he remained three years in England, agreed to reinstate him in the possession of Brunswick and Lüneburg. Having in 1189 refused to accompany Frederick on his crusade, he was again compelled to withdraw to England, but shortly after Frederick's departure he returned, and, concluding an alliance with the archbishop of Bremen, made a second attempt to recover his territories, but, though at first he gained several important victories, he was ultimately compelled in July 1190 to conclude a peace at Fulda, which secured to him scarcely any advantages from the contest. Emboldened by the hostile alliance formed against the emperor Henry VI in 1192, he again renewed the struggle, but after Richard of England fell into the hands of the emperor in the following year, he found it necessary again to give in his submission, and shortly afterwards a pledge of amity between the two houses was given through the marriage of the eldest son of Henry the Lion to Agnes, niece of Frederick I, and cousin of the reigning emperor. Henry died 6th August 1195 at Brunswick, and was buried in the church of St Blasie. Otto, his second son, became emperor under the title of Otto IV. A colossal statue of Henry was unveiled at Brunswick 4th July 1874. Though ambitious, headstrong, and pugnacious, Henry showed that while he possessed no small skill in the art of war he could appreciate the arts of peace, and he gave

the clergy not being enforced in England till 1103, this potency was considered no disgrace, and our author in several passages of his writings refers to his father with much filial respect. Received as a male child into the household of Robert of Blois, bishop of Lincoln, Henry not only continued to enjoy the advantages of its culture and affluence till the bishop's death in 1123, but he also secured the patronage and friendship of Alexander of Blois, who next succeeded to the see. There is reason to believe that he accompanied Alexander to Rome, probably in 1125 and 1111, and it was to him that he dedicated his *Historia Anglorum*, which was issued four times during the author's life, and in the last form came down to the accession of Henry II. (1154). The date of the author's death has not been preserved, but it is probable that the close of his life is approximately marked by the close of his history.

Henry of Huntingdon's *Historia* was first printed by Strick, *Rare Anglo-Saxon Manuscripts post Bedam* (London, 1866), and it was republished at Frankfurt in 1693. Books i, ii, iv, v, and vi were edited by Mr. Prieur for the Record Commission Collection, vol. i, 1841, and the whole work has been prepared for the Rolls Series by T. Arnold, 1880. An English translation by Thomas Forester forms a volume of Bohn's *Medieval Library* (1855). We have besides from Henry's pen in English to Henry I. on the accession of the Danish, Austrian, Plantagenet, and Roman kings and emperors (written in 1107), an Epistle to Wulfstan (one of his friends) containing an epitome of the British History of Geoffrey of Monmouth, which he had drawn from the *Annales* of the Ages of Ages, written then either, as Eusebius to his friend Walter on *Contempt of the World* or on *Bishops and other Illustrious Men of the Age* (written in 1117, and edited by Wharton in his *Anglia Sacra*, 1691). Nor must Henry's poetical pieces be forgotten, as they speak well for his culture and taste. Two 318 copies of his complete works preserved at Lambeth deserve to be specially mentioned, and the British Museum possesses several important receipts of his History. See Wright, *Biography of Henry of Huntingdon*, 1846; Foster, *Notes*, i, James Guillelmus, *Early Chemists of Europe* (England, 1879); and Arnold's elaborate introductions.

HENRY, JOSEPH (1797-1878), an eminent American physicist, was born in Albany, the capital of the State of New York, on the 17th of December 1797. He received his education at an ordinary school, and afterward at the Albany academy, which enjoyed considerable reputation for the thoroughness of its classical and mathematical courses. On finishing his academic studies he contemplated adopting the medical profession, and prosecuted his studies in chemistry, anatomy, and physiology with that view. He occasionally contributed papers to the Albany institute, in the years 1824 and 1825, on chemical and mechanical subjects, and in the latter year, having been unexpectedly appointed assistant engineer on the survey of a route for a State road from the Hudson river to Lake Erie, a distance somewhat over 300 miles, he at once embarked with zeal and success in the new enterprise. This diversion from his original bent gave him an inclination to the career of civil and mechanical engineering, and in the spring of 1826 he was elected by the trustees of the Albany academy to the chair of mathematics and natural philosophy in that institution. In the latter part of 1827 he read before the Albany institute his first important contribution, "On some Modifications of the Electro-Magnetic Apparatus." Struck with the great improvements then recently introduced into such apparatus by Mr. William Sturgeon of Woolwich, he had still further extended their efficiency, with considerable reduction of battery-power, by adopting in all the experimental circuits (where applicable) the principle of Schweigger's "multiplier," that is, by substituting for single wire circuits, voluminous coils. *Trans. Albany Institute*, October 10, 1827, vol. i, p. 29, 28. In 1828 and in March 1829 he exhibited before the institute small electro-magnets closely and repeatedly wound with silk-covered wire, which had a far greater lifting power than any then known. Henry appears to have been the first to adopt

insulated or silk-covered wire for the magnetic coil, and also the first to employ what may be called the "spool" winding for the limbs of the magnet. He was also the first to demonstrate experimentally the difference of action between what he called a "quantity" magnet excited by a "quantity" battery of a single pair, and an "intensity" magnet with long fine wire coil excited by an "intensity" battery of many elements, having their resistances suitably proportioned. He pointed out that the latter form alone was applicable to telegraphic purposes. A detailed account of these experiments and exhibitions was not, however, published till January 1, 1831 (*Silliman's Am. Jour. Sci.*, xiv, 400-408). Henry's "quantity" magnets acquired considerable celebrity at the time, from their unprecedented attractive power,—one (August 1830) lifting 750 pounds, another (March 1831) 2300, and a third (1834) 3600.

Early in 1831 he arranged a small office hall to be tapped by the polarized rotation of an "intensity" magnet, whose coil was in continuation of a rule of inviolable copper wire, suspended about one-third of an inch from the surface of the hall, and of magnetizing iron at a distance, or of a suitable combination of magnet and battery being so arranged as to be capable of such action. It was, therefore, the earliest example of a true "magnetic" telegraph, all depending on the induction of the Hall's law on the galvanometer or needle principle. About the same time he devised and constructed the first telegraphic circuit, with intermediate pole-changes (Silliman's *Am. Jour. Sci.*, July 1831, p. 810-812, and Silliman's *Annals*, *Electricity*, 1830, p. 604). He also discovered the induction of a current on itself, in a long helical wire, giving greatly increased intensity of discharge (Silliman's *Am. Jour. Sci.*, July 1832, xiv, 108). In 1832 he was elected to the chair of natural philosophy in the Albany College of Liberal Arts. In 1831 he continued and extended his researches "On the Influence of a Spinal Conductor in increasing the Intensity of Electricity from a Galvanic Arrangement of Single Pairs," a mention of which was made in the *American Philologist*, at New York, 1832, 1835 (*Trans. Am. Phil. Soc.*, v, 223-231, n. y.). In 1835 he continued the short circuit of his magnetic magnet (of 1831) with the small "intensity" magnet of an aqueous solution of sulphate of zinc, thereby establishing the fact that very powerful mechanical effects could be produced at a great distance by the agency of a very feeble magnet used as a current maker and breaker, or as a "trigger"—the action of latent forms of delay and receiving magnets. In 1837 he paid his first visit to England and Europe. In 1838 he made important investigations in regard to the conditions and range of induction from electrical currents,—showing that induced currents, although merely momentary, produce still other or tertiary currents, and thus on through successive orders of induction, with alternating signs, and with reversed initial and terminal signs. He also discovered similar successive orders of induction in the case of the presence of functional electricity (Proc. Am. Phil. Soc., 1838, p. 10, n. y.). Among many minor observations, he discovered in 1842 the oscillatory nature of the electrical discharge, magnetizing about a thousand needles in the course of his experiments (Proc. Am. Phil. Soc., 1841). He traced the induction of induction, by varying distances, magnetizing needles in the lower story of a house through several intervening floors by means of electric discharges in the upper story, and also by the secondary circuit. In 1841 with 220 feet distant from the wire of the primary circuit. In 1841, by experiments on the tenacity of iron-bubbles, he showed that the molecular cohesion of water is equal (if not superior) to that of steel, and hence, generally, that solids and thin liquids have an equal resistance to the application of cohesion (Proc. Am. Phil. Soc., iv, 66, 67, 68, 64, 85). In 1846 he showed, by means of a thermo galvanometer, that the solar spots radiate less heat than the general solar surface (Proc. Am. Phil. Soc., iv, 173-176).

In December 1846 Henry was elected secretary and director of the Smithsonian Institution, then just established. While closely occupied with the exacting duties of that office, he still found time to prosecute many of his original inquiries, and to the completion of accounts to public buildings, and the best construction and arrangement of lecture-rooms, into the strength of various building materials, he having only devoted much attention to meteorology, observing and in 1846 he was elected into the Smithsonian Institution, he (among his administrative acts) organized a large and widespread corps of observers, and made arrangements for simultaneous reports by means of the electric telegraph, which was yet in its infancy (Swinden, *Report*, 1847, p. 14). In 1847 he was the first to apply the telegraph to meteorological research, to have

the atmospheric conditions daily indicated on a large map, and to utilize the general barometric results in weather forecasts, and the first to embrace a continuous and a single system.—British America and Mexico being included in the field of observation. In 1869, on the reorganization of the American high-altitude system, he was appointed a member of the new board, and on the resignation of Adolphus Schuchert as its chairman, Henry, in 1871, became the presiding officer of the establishment—a position he continued to hold during the rest of his life. His diligent investigations into the efficacy of various illuminants under differing circumstances, and into the best conditions for developing their several maximum points of brilliancy, while greatly improving the usefulness of the art of burning, also led to the extensive use of the United States, effected at the same time a great economy of administration. His equally careful experiments on various acoustic instruments also resulted in giving to his country the most serviceable system of fog-signals known to maritime powers. In the course of these varied and prolonged researches from 1865 to 1877, he also made important contributions to the science of acoustics, and he established by several series of laborious observations, extending over many years and along a wide coast range, the correctness of Professor Stokes's hypothesis (*Report Brit Assoc.*, 1877, pt 2) that the wind exerts a very marked influence in reflecting sound beams. The complex conditions of such acoustical action he found to be exceedingly variable and capricious (*Report American Lighthouse Board*, 1874, 1876, and 1877). From 1868 Henry continued to be annually chosen as president of the National Academy of Sciences, and he was also president of the Philosophical Society of Washington from the day of its organization in 1871.

Henry was by general consensus the foremost of American physicists. He was a man of varied culture, of large breadth and liberality of views, of great force of argument, of great gentleness and courtesy of manner, combined with equal firmness of purpose and energy of action. He died at Washington, May 13, 1878. (S F B)

HENRY, MATTHEW (1652-1714), the author of the well known and justly popular *Exposition of the Old and New Testaments*, was born at Broad Oak, a farm-house on the confines of Flintshire and Shropshire, on the 18th of October 1652. He was the son of Philip Henry, one of the 2000 ministers who were ejected from their livings in 1662 for refusing to conform to the Act of Uniformity. Unlike the majority of his fellow-sufferers, Philip Henry, who through his wife was the possessor of private means, was spared all personal privation or hardship as the consequence of his nonconformity, and was thus enabled to give a good education to his son. Having received his preliminary education from his father and a tutor named Turner, Henry was next removed to an academy at Islington, whence he proceeded to become a student of law at Gray's Inn. His legal studies, however, not advanced far when he relinquished them for theology, to which he thenceforth devoted himself. In 1681 he became minister of a Presbyterian congregation at Chester, whence in 1712 he was translated to Hackney. Two years later (June 22, 1714), he died suddenly of apoplexy at Nantwich while on a journey from Chester to London. Henry's *Exposition*, the work by which he is now chiefly remembered, is a commentary of a practical and devotional rather than of a critical kind, ranging over the whole of the Old Testament and extending into the New as far as to the end of the Acts. At this point it was broken off by the author's death, but the work was finished by a number of clergymen, whose names are recorded in most editions of the book. In a critical point of view, it may be said to be quite valueless, yet its unflinching good sense, its discriminating thought, its high moral tone, its simple piety, and its altogether singular felicity of practical application, combine with the well sustained flow of its easy English style to secure for it, and deservedly, the foremost place among works of its class.

Besides the *Exposition*, Matthew Henry wrote a *Life of Mr Philip Henry*, *The Comforter's Companion*, *Directions for Daily Communion with God*, *Method for Prayer*, and *A Seraphical Catechism*, all of which, along with numerous sermons, have been frequently reprinted, both separately and in complete editions of his *Miscellaneous Works*. His life has been written by W Tong (London, 1818), by Davy (added to *Exposition*, ed 1841), by Hamilton (*Christian Biography*, 1859), by C Chapman (1860), and by J B Williams (1828, now ed 1866).

HENRY, PATRICK (1736-1799), an American statesman and orator, was born at Studley, Hanover county, Virginia, May 29, 1736, the second son in a family of nine children. His father, John Henry, an emigrant from Aberdeen, Scotland, was a nephew of Robertson the historian, and had risen to some eminence in the county, filling the offices of surveyor and presiding magistrate. Patrick Henry was educated at a little school near his home, and, after the age of ten, by his father, who had opened a grammar school at his residence. In early life he showed no marked proficiency in his studies, except perhaps in mathematics, but was noted chiefly for a love of outdoor sports. At fifteen he became a clerk in a country store, and at sixteen he entered into partnership as a stockeep with his elder brother, but the business was unsuccessful, and a second attempt at stockeeping ended likewise in failure. Meanwhile the indifference to learning which marked his boyhood was replaced by a love of history, especially that of Greece and Rome, and his habitual idleness was overcome by his admiration for Livy, whose history he thenceforth read through once every year. At twenty-four, by his admission to the bar, Henry entered on the career that eventually brought him fame and fortune, although his income for some years was in keeping with his lack of previous preparation. At twenty-seven he was called to the bar, as counsel for the collector of the county, in what became known as "the prison's cause." His unexpected display of eloquence on the side of the people procured him an extravagant recognition and the title of "the orator of nature." Business poured in upon him, his popularity concealing his deficiencies, and his success was assured. In 1765 he was elected to the House of Burgesses, where he distinguished himself as the author of certain resolutions against the Stamp Act, the last of which,—providing that "the General Assembly of this colony have the sole right and power to lay taxes and impositions upon the inhabitants of this colony,"—though passed by a majority of only one, was the key note of the struggle for independence. In 1769 he was admitted to practice in the general court, where he attained eminence in criminal cases before juries. In 1773 he was a member of the "committee of correspondence for the dissemination of intelligence between the colonies." In the following year he was chosen delegate to the Virginia convention, which was the first public assembly to recommend an annual "General Congress," and to the "Old Continental Congress," but his success there as an orator failed to conceal his defects as a practical statesman. In 1775, in the Virginia convention, he delivered a remarkable speech in moving that the "colony be immediately put in a state of defence," and at the head of a body of militia he forced the royal officials to pay £330 for powder clandestinely removed by order of Governor Dunmore. He was appointed by the convention colonel of the first regiment and commander of all the forces to be raised in Virginia, but a misunderstanding with the "committee of safety" led to his resignation. He was a member of the second Continental Congress of 1775, and of the Virginia convention of 1776, which had been elected "to take care of the republic," the royal governor having fled. They framed a new constitution, and elected Henry the first republican governor, on the first ballot. He was re-elected in 1777 and 1778. In 1780 he became a member of the legislature, where he continued until he was again elected governor in 1784. In 1786 he withdrew through the pressure of debt, having "never been in easy circumstances." In 1787 he was chosen a delegate to the "Federal Constitutional Convention," but did not attend. He had resumed his practice to better his fortunes. In 1788 he was a delegate to the Virginia convention for ratifying the Federal Constitution, which he vehemently

opposed as dangerous to the liberties of the country. In 1791 he declined re-election to the legislature, continuing, "though necessity rather than choice," the practice of the law, but usually in great and unremunerative cases only. Finally, in 1794, having not only paid his debts but secured affluence, he withdrew to private life. In 1795 he declined the position of secretary of state in Washington's cabinet, in 1796 the nomination for governor of Virginia, and in 1797 the mission to France, offered by President Adams. In 1799, however, he suffered himself to be elected to the State legislature, where he wished to oppose what he deemed the dangerous doctrine of the Virginia resolutions of 1798, but he did not take his seat, his death occurring on the 10th June. Henry's manners were plain, his temper cheerful, and his habits temperate. His eloquence, of which some fragmentary specimens have become household words among his countrymen, was vivid and striking. Almost entirely a gift of nature, it was equal to every occasion, and, with the aid of a clear voice and perfect articulation, it was of marvellous power in bringing his hearers to a quick decision.

HENRY, ROBERT (1718-1790), the author of the *History of Great Britain written on a new plan*, was the son of a farmer, and was born in the parish of St Ninians near Stirling, 18th February 1718. He received his early education at the school of his native parish, and at the grammar school of Stirling, and after completing a course of study at Edinburgh University, became master of the grammar school of Annan. In 1740 he was licensed to preach by the Annan presbytery, shortly after which he was chosen minister of a Presbyterian congregation at Carlisle, where he remained until 1760, when he was removed to a similar charge at Berwick-on-Tweed. It was during his stay at Berwick that the idea of his *History* first occurred to him, but the death of books and the difficulty of consulting original authorities compelled him to postpone the execution of his design till his removal to Edinburgh, as minister of New Greyfriars, in 1768. The first volume of his *History* appeared in 1771, and the others followed at irregular intervals until 1785, when the fifth was published, bringing down the narrative to the Tudor dynasty. The work was violently assailed by Gilbert Stuart, but the attack was overdone, and although it for a time hindered the sale, the injury effected was only temporary. For the volumes published in his lifetime Henry realized as much as £3300, and through the influence of Lord Mansfield he was in 1781 rewarded with a pension of £100 a year from George III. In 1784 he received the degree of D.D. from the university of Edinburgh. He died in 1790 before his tenth volume was quite ready for the press. Four years after his death it was published under the care of Malcolm Laing, who supplied the entire chapters v and vi, and added an index. A life of the author by Sir Henry Wallwood Moncreiff was prefixed to the volume. The novel feature in Henry's *History* was that he combined with the narrative of the great political events of each era an account of the domestic state and social progress of the people within the same period. His researches were conducted with great care, and his work embodies much novel and curious information, but the comprehensiveness of his plan, and the limited character of the historical sources then available, greatly militated against the accuracy of his narrative. Notwithstanding also that the work is well arranged, and written with clearness and simplicity, its defects as an authority are not compensated for by any peculiar excellences of style, by originality or vigour of reflexion, or by any special skill in the delineation of character.

A Continuation of Henry's History to the Accession of James I., by J. Pettit Andrews, appeared in 1796. An account of the attack of Gilbert Stuart on Henry is given in Dunell's *Colloquies of Authors*.

HENRY, WILLIAM (1775-1896), a distinguished chemist, son of Thomas Henry, an apothecary and author of some works on chemistry, was born at Manchester, December 12, 1775. After completing his education at an academy in Manchester, he was for some years private secretary to a physician, and in 1795 he began the study of medicine at the university of Edinburgh. Prudential considerations compelled him, however, to interrupt his studies at the conclusion of his first session, and he did not resume them till 1805, two years after which he received the diploma of M.D. For some time he practised as a physician in Manchester, but on account of delicate health, caused by an accident, he was ultimately compelled to retire from his profession. He nevertheless carried on his original researches in chemistry, for which he found great facilities in connexion with his father's business, and from 1797 till his death he continued to enrich the *Transactions* of the Royal Society with contributions on his favourite science, especially in regard to aeriform bodies. His first communication was an attempt, in opposition to Austin, Beddoes, and others, to establish the title of carbon to rank among the elementary bodies, but discovering afterwards a fallacy in his reasoning he corrected it in a subsequent paper. In 1800 he published in the *Philosophical Transactions* his experiments on muriatic acid gas, made with the view of disengaging an imaginary unknown element supposed to be associated with oxygen in the composition of the gas, but after the discovery of the real nature of the acid by Davy he was one of the earliest converts to the new theory. In 1803 he published his elaborate experiments on the quantity of gases absorbed by water at different temperatures and under different pressures, with the result of establishing the law that "water takes up of gas, condensed by one, two, or more additional atmospheres, a quantity which would be equal to twice, thrice, &c., the volume absorbed under the common pressure of the atmosphere." In 1808 he described in the *Philosophical Transactions* a form of apparatus adapted to the combustion of larger quantities of gases than could be fitted in endometric tubes. In the same year he was chosen a fellow of the Royal Society, and in 1800, for his valuable contributions to the *Transactions* of the society, he was awarded the Copley gold medal. For the next fifteen years he continued his experiments on the gases, making known the results of them from time to time to the society. In his last communication, in 1824, he claimed the merit of having conquered the only difficulty that remained in a series of experiments on the gaseous substances issuing from the destructive distillation of coal and oil, and proved the exact composition of the fire-damp of mines. But though Henry's experiments had reference chiefly to aeriform bodies, his acquaintance with general chemistry is proved by his *Elements of Experimental Chemistry*, a work which combines great literary elegance with the highest standard of scientific accuracy. He had also collected materials for a history of chemical discovery from the middle of last century, but did not live to carry out the project. It is indeed to be regretted that he did not contribute more to the literature of science. His biographical notices of Priestley, Wollaston, and Davy may be regarded as models in that species of composition. At intervals during his lifetime Henry suffered much from neuralgic pains. These became so severe as to render the extirpation of the principal nerves of the hand necessary, but this failed to afford the expected relief, and ultimately the irritation of the whole nervous system deprived him of sleep, and caused his death on September 2, 1896.

HENRYSON, ROBERT (c. 1425-1506), one of the early Scottish poets, and the author of the first specimen of the pastoral poetry of his country, is usually designated schoolmaster of Dunfermline, and according to tradition

he was the ancestor of the family of Henryson or Henderson of Fordell, in the county of Fife, one of whom, James Henryson, was king's advocate and justice-clerk in 1494. Of the poet's parentage and early history, however, no certain information can be discovered. From various circumstances known about him he must have been born about the year 1425. He seems to have been educated abroad, as his name does not appear in the registers of the university of St Andrews, the only one then existing in Scotland, and from an allusion in one of his poems, his attention was probably given to the study of law. In 1462 his name appears in the list of members of the newly founded university of Glasgow as "Magister Robertus Henyson in artibus licentiatu8 et in decretis Bachelarius." Henryson seems, in a literary public, to have practised at Dunfermline as a notary public. His decease in or shortly before 1506 is alluded to by Dunbar, who, in his lament for the "makaris" or poets, says of Death—

"In Dunfermline he has done iver
Gud Maister Robert Henyson"

Of the writings of Henryson that have come down to the present time, his *Treatise of Cresseid* may be considered the chief. It was composed as a continuation, or supplement to Chaucer's *Probes and Cresseid*, which was one of the most popular poems in the English language. Henryson resumes the story where Chaucer leaves off, and completes it by inflicting a suitable punishment on the false Cresseid. This continuation displays so much skill that it has been included in all the best editions of Chaucer, as if it had been the work of that poet himself. Another poem, *Robene and Makyne*, though slight, is remarkable, as it is the first known specimen of pastoral poetry in Scottish language, while his *Dirige Noctis* is amongst the oldest examples of ballad poetry. His metrical version of thirteen of the *Fables of Aesop* is perhaps the best known of his works. To each fable is appended an application of moral. It shows his allusion to the opinions of the people and the moral state of the country during the feeble reign of James III. His excellent *Fable of Ophione*, though a vulgar performance, exhibits his familiarity with the school of the La Fontaine of his time. Some of the poems of Henryson have been preserved in the Bodleian MS. in the Auchinleck Library, the Bannatyne MS. in the Advocates' Library, Edinburgh, the Maitland MS. in the Pepysian Library, Cambridge, and the Harley MS. British Museum. His *Ophione and Every One* was printed at Edinburgh by Clepmack & Myllar in 1568. The *Treatise of Cresseid* was printed at Edinburgh by Henry Charteris in 1593. The poem of *Robene and Makyne* and the *Treatise of Cresseid* were reprinted for the Bannatyne Club in 1821. The *Life of Fables* were printed at Edinburgh by Leckie in 1870, at London by R. Smith in 1877, and again at Edinburgh by Andrew H. in 1881. This first edition was reprinted for the Maitland Club in 1832. A collection of the poems of Henryson, containing nothing to be denied, was printed at Edinburgh in 1885, under the editorial care of Dr David Laing.

HENSLOWE, PHILIP, a contemporary of Shakespeare, whose name continues of interest from his intimate association with the history of the theatre during the great dramatist's career. Originally, it would appear, a dyer and afterwards a starchmaker, he is ready to turn to any profitable speculation, he probably began his connexion with the stage in 1584 by becoming "joint lessee of the Swan theatre on the Bankside, or of the ground on which it stood." From 1591 to his death in 1616 he was in theatrical partnership with the more famous Edwin Alleyn, who in 1592 married his step daughter, Joan Woodward. In 1613 he was appointed sergeant of the king's bear-warden, to take charge of a lion and certain other beasts presented by the duke of Savoy. Henslowe's business diary from 1593 to 1609 has happily been preserved in Alleyn's College at Dulwich, and, though evidently the work of an ignorant man, it is of prime importance for its miscellaneous store of items in regard to the first appearance of plays, the sums paid to the authors, the theatre receipts, and so on. It was edited for the Shakespeare Society in 1841 by J. Payne Collier, who, however, found that the MS. had suffered considerable mutilation at the hands of mercantile antiquary hunters since the time when it was employed by its original discoverer Malone. See ALLEYN.

HENZADA, a district in Pegu division, British Burma, lying between 16° 49' and 18° 30' N lat., and between 94° 51' and 96° 7' E long., with an area of 4047 square miles. It is bounded on the N by the Prome district, on the E by the Pegu Yomas, on the S by Rangoon, Thonkwa, and Bassoon districts, and on the W by the Aitken Yoma range. Henzada district stretches from north to south in one vast plain, forming the valley of the Irawadi, and is divided by that river into two nearly equal portions. This country is protected from inundation by immense embankments, so that almost the whole area is suitable for rice cultivation. The chief mountains are the Aitken and Pegu Yomas ranges. The greatest elevation of the Aitken Yomas is Hensada, situated in the latitude of Myan-cung, is 4003 feet above sea-level. Numerous torrents pour down from the two boundary ranges, and unite in the plains to form large streams, which fall into the chief rivers of the district, viz., the Irawadi, Hlang, and Bassein. The forests comprise almost every variety of timber found in Burma.

The inhabitants of Henzada district in 1876 numbered 501,218. The number of immigrants into the district during the ten years ending 1876 was 90,797. The chief occupations of the people is agriculture. Nearly all the large towns are on the right bank of the Irawadi. The chief towns have populations as follows—Hensada, 16,807; Kyau-kling, 8761; My in-cung, 6578; and Mong-ye, on the left bank of the Irawadi, 16,779. The principal crops of the district are rice, assamum, cotton, and tobacco. The total area under cultivation in 1876 was 803,018 acres. The other products are cotton, mungo, oil seeds, pepper, milk, pulses, corn, and betel nut, gun vine, &c. The revenue in 1876-77 was £132,748. In 1876 the police force consisted of 400 men.

The district was once a portion of the Tiling kingdom of Pegu, afterwards annexed to the Burmese empire in 1755, and has no history of its own. During the second Burmese war, in 1824, it had been seized, the Burmese on the right bank of the Irawadi crossed the river and offered resistance to the British, but were completely routed. Meanwhile, in Tharwadi, on the country east of the Irawadi, and in the south of Henzada, much disorder was caused by a revolt, the leaders of which were, however, defeated by the British, and their gangs dispersed.

See LINGWONN.

HEPHESTION, son of Amyntor, a Macedonian, a friend of Alexander the Great. The two, according to Quintus Curtius (iii. 12), were companions in childhood, but beyond this old-standing connexion we find no evidence of such qualities in Hephestion as deserved the passionate attachment of Alexander. The king, however, seems never to have been blind to his real character, and to have made a marked distinction between him, as the friend of his private life, and his intimate hours, and such men as Craterus, whom he could entrust with important enterprises. We do not hear again of Hephestion till 334 B.C., when he accompanied the king on his visit to Troy.

Many tales are told of the close intimacy subsisting between them; for example, Plutarch says that when a letter of very delicate and private nature from Olympias was handed to Alexander, Hephestion, according to his custom was reading it over his shoulder, when Alexander without uttering a word took his ring off his finger and pressed it on his friend's lips. In the later campaigns of Alexander in Bactria and India, we find Hephestion charged with important commands. He was rewarded with a golden crown and the hand of Dryopis, the daughter of Darius and sister of Alexander's own wife Statira (324 B.C.). In the end of the same year he died very suddenly at Babatana. Alexander tried to relieve his grief by paying the most extravagant honours to his friend. A general mourning was ordered over Asia, at Babylon a funeral pile was erected at a cost of 10,000 talents, and temples were erected to him as a hero.

HEPHESTION, a grammarian of Alexandria, author of a work on Greek metres called *ὑπερμετρον ἡμετρον*. This work is most valuable as the only complete work on the subject that has been preserved. The author is pro-

bably the same as the grammarian that acted as tutor to the emperor Vespasian about 150 A.D.

HEPHAESTUS, a word of uncertain derivation but certainly pre-Greek in formation (Kuhn, *Zeitsch.*, v. 214), denotes among the Greeks a god who represents the power of fire and its appliance in the operations of daily life, corresponding to the Latin Vulcan. A clear distinction must be drawn between the Hellenic god and the deity worshipped by the Pelagic races. Though the word Hephæstus is used by Homer in the sense of fire, yet in the Hellenic god no elemental idea is at all prominent. The Hellenic religion had raised itself far above such conceptions of the divine power, and its gods were moral powers.

Zeus, the ruler of the world, whose will, according to the finest Hellenic conception, is fate, is surrounded by a court in which Hephæstus appears as the divine artificer, an object rather of laughter than of respect to the other gods. No worship was paid him, for his altar at Olympian seems not to have been an ancient institution. The fire of the hearth, as the centre of family and city unity, is now personified under a purely Greek name, Hestia, but here again it is not the elemental but the moral conception that is the predominant idea in the goddess (see Hæstia). The similarity between the divine artificer of the Greeks and the Finnish Iimaine or the German Wieland, who has degenerated finally into the Weyland Smith of Scott's *Kennilworth*, has been often pointed out, and the standpoint of them all is the smith who makes the new sun every morning (see Manhardt, *Zeitsch. f. Ethnol.*, 1875, p. 221). The round disk of the sun has in poetic treatment become the shield of Achilles, whose fabrication is the great deed of Hephæstus in the *Iliad*. This artificer is naturally represented as married to the dawn, Aphrodite or Chæris (see Hæclys), as Wieland marries the Swan maiden, and the guild of Aphrodite which Hephæstus made is the halo of rays that heralds the rising sun. All wonderful works came to be attributed to the divine smith, in particular the house of the gods has been made by Iimaine and by Hephæstus, and they also, like Wieland, have made metal figures that move and almost equal living beings. In general the art of working metals by the hammer is under his patronage—a fact which points out that at as one of the very oldest known to the race (Conze, *Götter- und Helden-Gestalten*, s.v.). In local traditions a set of oldish creatures like the Indian Dactyles or the dwarfs in German legend were often put in place of this divine smith. The belief which in Lipara and Strongyle was associated with Hephæstus, that any one that put a lump of iron in a certain spot at night found next morning the article he wished ready made, provided he paid the required price, is in some parts of Germany attached to a corresponding set of dwarfs. An all-omniscient character often attached to the works of Hephæstus, as to that of the Telchines or the German dwarfs. Other points in the Hellenic Hephæstus can be explained only by a reference to the worship of the older Pelagic tribes. When Homer (*Il.*, i. 593) says that he was ruled by his father Zeus down to the earth, the reference to the lightning is unmistakable (Welcker, *Gr. Gott.*, i. 601). Again the weak legs always attributed to Hephæstus remind us of the serpent legs of his son Enchithomus, and serpents occur often as symbols of lightning. Homer (*Il.*) says that Hephæstus fell on Lemnos, whose inhabitants tended him, he evidently considers that the Hellenic deity was identical with the Pelagic god. Wherever a Pelagic race is most certain, that the god is found, associated with the Cabiri, he is the Cabirus *par excellence* (Hæclys, iii. 87). Among these tribes the power of fire was considered the life-giving and reproductive power of nature, and the deity in whom it was embodied became the chief object of their worship.

Inance on the coasts of Imbros an idyllic Hephæstus appears. As Greek influence prevailed among the kindred Pelagic tribes, their native worship survived in the form of mysticism, and their proper gods, whose nature was revealed to the initiated, became in popular tradition heroic or demonic figures who were the founders of the mysteries (v. Hæclys, and comp. Lenormant in D'Alembert's *Dict. des Antiquités*, at "Cabéri"). This Hephæstus or Cabirus is the lightning that has descended to earth and become the origin of all life, and according to Pindar (*P.*, 162) the first man. The original conception, vague and wide like all primitive ideas, is that the heavenly and the subterranean fire are identical with the fire on earth. In both theunderstorm and dawn the fire of the sun is relighted after being for a time extinguished. In both the alternation of light and darkness was the prominent fact. In the thunderstorm the sparks emitted from the sun descend as the lightning to earth. This original power of fire has been developed in various ways, the higher thought of the Greeks rejected such a naturalistic deity as the Pelagic found congenial, while in Athens, where the Pelagic element was very strong, Hephæstus occupied a correspondingly high place, and is in close relationship with Athena. In many economies, as the Lampadephoria, they were associated, and at the Apollonia honour was paid to Zeus Phædrus, Athena, and Hephæstus. In the oldest traditions they were a pair, married, and then son Enchithomus was the parent of the Athenian people. When the Hellenic conception of the maiden-goddess Athena prevailed, the connexion was transformed into an unsuccessful attempt of Hephæstus at a union with Athena. But the marvellous birth of Enchithomus is an ancient feature, as it occurs in Vedic tradition (Kuhn, *Zeitsch.*, i. 413).

Small images of Hephæstus stood on every hearth at Athens, and the Amphidromia round the hearth he was the deity whereby the newly-born child was adopted into the family. In the oldest Greek art Hephæstus is a bearded man fully clad, carrying a hammer. This hammer, which the Cabirus of Thessalonica carries, is doubtless in its origin, like the hammer of Thor, the lightning-bolt of hammer with which was shivered the tower when the sun was hid during the winter darkness. An undignified and comic character is, however, often apparent, when he wears short, workman's clothes, and is the dignity proper to a god. The rising type in later art is a bearded man with a certain resemblance to Zeus, wearing a close cap, carrying the traditional hammer, and clad in a short, girton tunic which leaves the left shoulder free. (W. M. R.)

HERA, a word of which many different derivations have been proposed, is the name of a Greek goddess, corresponding to the Latin Juno, who according to the conventional type is the wife of Zeus and queen among the gods of Olympus. In the literature of the Greeks Hera fills a very conspicuous place—the strong, haughty, and rebellious character, full of intense hatreds and likings, which was associated with her, made her a picturesque and dramatic figure. According to this conception of her, she was daughter of Cronus and Rhea, and at once sister and wife of Zeus. She was always the bitter enemy of all the heroines who were the successive objects of her husband's love, and her persecution of them and of their children often forms the theme of poems from the *Iliad* (xxiii. 119) downwards. This type, which is the familiar one in all literature, had never any real existence in religion, but had been gradually elaborated by poets from the actual deity worshipped in various parts of Greece, and from the legends transmitted to the Greeks from earlier races.

The most characteristic and fundamental point in the worship of Hera is the *tepe γάμος*, her marriage with Zeus, and from this any explanation of the conception involved in the goddess must start. Again in Greek legend we learn that a close connexion exists between Hera and the cow, and that probably she was originally thought to have the

form of a cow. These facts at once direct us to the ancient Aryan idea, described in detail by Gubernatis (*Zoolog Mythol.*, i.), that the divine power as the origin of all life is embodied in a pair of gods male and female, whose fertility leads to the conception of them as a bull and a cow. This pair, the bull and the cow, appear in various fantastic developments in Greek legend. For example, Zeus himself in the form of a bull carries off Europa, and we learn from Hesychius that Europa is an epithet of Hera. Looking at the matter from this point of view, we find that the question so much disputed among mythologists, whether the naturalistic conception out of which the Greek goddess has developed be earth or moon, is a mere matter of words, and that there is no real discrepancy between the two views. The fine and vague conceptions of primitive men refuse to be shut into the precise and unsuited terminology of modern thought. Ideas which to us are very different were once expressed by the same root (see Curtius, *Grundr.*, iii. 284, No. 415). Thus we have in the *Rig Veda*, vi. 51, 5, a clear trace of the view so common in all mythologies, whether in the theology of Heaven or of the New-Worlders, that Heaven and Earth are the primitive pair of deities, parents of all existence and first of the gods. This view is of peculiar importance in old Roman religion (cf. Schwegler, *Rom. Gesch.*, i. 328, 422, 430), and also among the older Italic tribes of Greece. But this same divine power, the primitive Aryan, beheld in all the great operations of nature in each they saw the prototype of all earthly works, and in seeking here the origin of life, they found it in the same divine pair, the bull and the cow. In particular, the various alterations of light and darkness appealed to their minds most strongly, and occupy great part of their mythology. In the transitions between light and darkness, and especially in the struggle between night and day, the idea of a pair is not so prominent, and in legends the marriage of moon and sun does not figure very conspicuously. Yet we sometimes find the marriage of the moon and sun described exactly in the way of this *tephs yugas*. In *Rig Veda*, x. 85, it is the type of all earthly marriages (see Weber, *Ind. Stud.*, v. 178). A Slavonic story makes the marriage of moon and sun annual: they part every winter and meet again in the first days of spring, and a Lettish song makes the marriage of moon and sun in spring (Mannhardt in *Zft f. Ethnol.*, 1875, p. 316). The moon too is often symbolized as a cow. The mystic union takes place in the spring when life returns to the earth, and the voice of the cuckoo is heard in the land. Hence in the legend Zeus, enamoured of his sister Hera, is said to have flown to her in the form of a cuckoo dipping wet, and to have been in pity received into her bosom. In various parts of Greece where traces of the under tribes are strongest, there remains a coarser conception of this union, and in the popular accounts the marriage customs of the country are reflected (see Welcker, *G. Götterl.*, i. 364 ff.). Lectum in the Trojan Ida and Ochia in Euboea, on the summits of which this union is placed by the legends of the countries, received their names from it. As we might expect, this idea is too purely naturalistic to form any part of the moral Olympian religion. Hera appears thus as the wife of Zeus, but all deeper meaning has disappeared. The old tale remains in the mythological legends, which always cling as a degrading appendage to this religion, and we find it in Homer (*Il.*, xiv. 294) transformed into an incident of the Trojan war. In the popular religion, however, Hera, as first the virgin, then the sacred bride, and finally the lawful wife of Zeus, and the patron of all marriage, is a very prominent figure. Every year the festival of Hera was celebrated with special reference to this union in Argos, Samos, Elis, Plataea, and many other parts of Greece. The festival took place in a month named

Targhmon at Athens, *Hepaios* in some other parts of Greece. Hence we have such epithets of Hera as *Nūphora*, *νυμφεομένη*, *τελέια*, *γαμήλια*, and the bridal veil is one of her most frequent attributes. Hera was married to Zeus in early youth, and knew no other marriage. Hence she is the patron goddess of all married women, the protectress of the sanctity of marriage, and she demands the utmost purity from her votaries. In this respect Hera approaches closely to Demeter Thesmophoria. As the winter is a time of barrenness and separation, so we have in Attic drama, Aegive, and Samian legend the angry Hera, the widow Hera, separated from her husband.

Other points in Hera again point directly to the moon. Like all other forms of the moon goddess (see *HEGATIS*), she presided over child birth, and under the epithet *ἐλεθβια* was invoked by women in labour. This idea arises from the moon's use as measure of time and number of the months. Then the epithet became gradually developed as a daughter, or set of daughters, of Hera, named *Eileithyia*. Beauty is another characteristic of all moon-goddesses, and of Hera also. In her festival at Lemnos prizes were assigned after a contest to the most beautiful woman. Large eyes were part of the artistic type, and *βόρεια* is one of her most constant epithets in literature.

Euboea, the very word being an epithet of the goddess, was one of the chief seats of her worship, of Hera. So in Boeotia, her temples both at Thebes and at Plataea were famous. In the *Ilwad*, Argos, Sparta, and Mycenae were the cities which she specially protects and loves. Argos was always one of the chief seats of her worship, and the Heraion there was one of the chief temples of Greece. At Olympia also was a very ancient temple, the Heraion, the ruins of which have been recently brought to view by the German exploring expedition. At the Laconian promontory Hera was the patroness of the union first of the Achaean cities and afterwards of a wider circle of the Greek colonies. But the Hera of Samos was perhaps the most famous, and most characteristic appearance of the goddess. There the Greek goddess was amalgamated with another, who was worshipped by the kindred tribes among whom the Greeks settled, and who is clearly the same as the Atimone of Ephesus or Clazomenae, and so on coins of Samos we find Hera standing with the sun and moon on either side of her head, exactly like Artemis on coins of Ephesus.

We find such rude images of Hera as a plank at Samos, or a branch at Thebes. A very ancient statue by Smilis stood in her temple at Samos, the golden, veiled, stood erect, clad in a long chiton, holding in each of her outstretched hands a sphinx. In the earlier vase paintings she is hardly to be distinguished from Artemis. She appears, just like Artemis, raising torch and bow, and wearing the kalathos on the stephanos, and several figures which others consider to be Artemis are by Overbeck explained as Hera. In representations of the Judgment of Paris there is often nothing to distinguish her from Aphrodite. Her characteristic symbols are the veil or sceptre, and she often carries a fruit. Numerous vase paintings, representing a bridal procession, which *Forster* (*Zeus und Hera's Hochzeit*) believes to represent the *tephs yugas*, are by Julius Overbeck (*Hera*, p. 174) maintained that only three certain representations of this scene exist. The oldest statue by Polykles in the Heraion at Argos showed her enthroned, wearing the *ερεφρόδη*, holding in one hand a pomegranate and in the other a sceptre, on the top of which was a cuckoo. There is no evidence to determine what was the character of the face, nor whether it had its distinctive meaning the ideal type of Hera (Overbeck, *Zeus*, p. 51). The *Parthenon* bust at Naples represents a type more antique than the style of Polykles. Herakles made this great statue of Hera, at Megara, Maroneia, and Plataea. The last, which represented Hera *clara* standing, is known to us by many imitations in the Vatican and elsewhere. From the works of these two great artists we may suppose that the highest type of Hera was elaborated in the Athenian school about the middle of the 4th century, and in the famous statue of the Villa Ludovisi it is probable that we have the actual work in which this type was first attained. Thus bust, which has been often described, and especially by Goethe, was probably one of the head of a colossal seated statue. (W. M. RA.)

HERACLEA, or HERACLEIA (in French, *Heracle*), the name of several ancient cities in various parts of the area of Greek colonization, so called in honour of Heracles, or Hercules.

I HERACLEA, a city of Magna Græcia, which lay between the rivers Aciris and Sius, not far from the shores of the Gulf of Tarentum, near the site of the modern village of Policoio. It appears to have been a joint colony of the Tarentines and the Thurians, and to have risen after the destruction of the neighbouring city of Sius. That it attained to no small prosperity and became the seat of the great politico-religious assembly of the Italian Greeks is notwithstanding all that can be said of its earlier history. By Alexander of Epirus it was deprived of this privilege in favour of Thurii. Pyrrhus was victorious in its vicinity in the first battle he fought with the Romans, 280 B.C., and two years later the city formed an alliance on advantageous terms with the conquerors. In the time of Cicero it was still comparatively prosperous. The *Tabula Heracleensis*, found at Luce near the ruins of the city in 1753, are two bronze tablets, or rather fragments of tablets, containing on one surface a Greek inscription relating to temple domains and on the other surface a copy of the famous *Lex Julia Municipalis* published by Julius Cæsar in 45 B.C. They are preserved in the Museo Nazionale at Naples, and one of them is distinguished as the *Lex Britannica* and the other as the *Lex Neapolitana*. Both inscriptions are given in Marrocci, *Commentarii in un Regni Heracleensis Municipales tabulas Heracleenses* (Naples, 1754-55), and the Latin one will be found in Munro, *Inscriptiões* (vol. II), and Maubold, *Monumenta legalia*. See also Savigny, *Zurichs ur fur geschichtliche Rechtswissenschaft* (vol. IX) and *Vermischte Schriften* (vol. II, Berlin, 1850).

II HERACLEA, a city of Sicily, at the mouth of the Halycus (the modern Platani), not far from the promontory now known as Cape Bianco. It was distinguished from the other Heracleas by the surname of Minoe, which was explained as referring to its foundation by Minos of Crete. Its name frequently occurs in connection with the Carthaginian occupation of Sicily, and it was in the neighbouring sea that the Carthaginian fleet was routed by Regulus and Manlius in 256 B.C. The Romans introduced a colony.

III HERACLEA PONTICA, a city on the coast of Phrygia in Asia Minor, easily identified with the modern Bender Eiegit or Erekit, at the mouth of the Kizil-ye on the Black Sea. It was founded by a Megarian colony, which soon subjugated the native tribe called the Minudynians, and extended its power over a considerable territory. The prosperity of the city, rudely shaken by the Galatians and the Bithynians, was utterly destroyed by Aulus Cotta in the Midtridatic war. It was the birthplace of Heracleides Ponticus. The modern town is best known for its coal mines, from which Constantinople receives a good part of its supply. See Pölsberg, *De Rebus Heracleæ*, Brandenburg, 1833, and O Kammel, *Heracleotica Beiträge zur alten Gesch. der griech. Colonisation im nordl. Klein Asien* (Progr. des Gymn. zu Plauen, 1860).

IV HERACLEIA SINTICA, a town in Thracian Macedonia, to the south of the Styrmon, the site of which is marked by the village of Zerrôrhori, and identified by the frequent discovery of local coins.

V HERACLEA, a town on the borders of Caria and Ionia, near the foot of Mount Latmus, whence it is usually distinguished as the Latmian. In its neighbourhood was the burial cave of Endymion. See Rayet and Thomas, *Mémoires du Golfe Latmique*, Paris, 1877.

For Heracleia Trachina see TRACHIS, and for Heraclea Perinthus see PERINTHUS.

Heraclea was also the name of one of the Sporades, between Naxos and Ios, which is still called Raklia, and

bears traces of a Greek township with temples to Tycho and Zeus Lophites. See Baumerstor in *Philologus*, vol. IX.

HERACLEON, a Gnostic who flourished about 125 A.D., probably in the south of Italy or in Sicily, is generally classed by the early heresiologists with the Valentinian school of heresy. In his system he appears to have regarded the divine nature as a vast abyss in whose pleroma were seeds of different orders and degrees,—emanations from the source of being. Midway between the supreme God and the material world was Demurgus, who created the latter, and under whose jurisdiction the lower, animal soul of man proceeded after death, while his higher, celestial soul returned to the pleroma whence it first issued. Heracleon seems to have received the ordinary Christian Scriptures, and Origen has preserved fragments of a commentary by him on St John's gospel, while Clement of Alexandria quotes from him what appears to be a passage from a commentary on St Luke's gospel. These writings are remarkable for their intensely mystical and allegorical interpretations of the text. The portions of the commentary on St John's gospel have been brought together by Giabe in the second volume of his *Spicilegium*.

HERACLES. See HERACLES.
HERACLESIDES, assumed POMPICIUS, a Greek metæphysical writer who flourished the 4th century B.C., was born at Heraclea in Pontus. Removing to Athens, he is said to have been a disciple successively of Speusippus, Plato, and Aristotle. According to Suidas, the second of these philosophers, on departing for Sicily, left his scholastic in the charge of Heraclesides. The latter part of his life was spent at Heraclea. Of his private history we have few authentic details. He is said to have been vain and fat, and to have maintained such state in Athens that the wits changed his surname into Pompicius, or the Showy. Various idle stories are related about him. On one occasion, for instance, he was afflicted with fumes, and the Pythiess at Delphi, bribed by Heraclesides, assumed his inquiring townsmen that the death would be stayed if they granted a golden crown to that philosopher. This was done, but just as Heraclesides was receiving his honour in a crowded assembly, he was seized with apoplexy, while the dishonest priests perished at the same moment from the bite of a serpent. On his death-bed he is said to have requested a friend to hide his body as soon as life was extinct, and, by putting a serpent in its place, induce his townsmen to suppose that he had been carried up to heaven. The truth was discovered, and Heraclesides received only ridicule instead of divine honour.

He wrote on a great variety of subjects, but only one fragment, *On States of the soul*, is now extant. This was published with the *Varia Historia* of Erihan at Rome in 1546, but the best editions are those of Koller (Halle, 1804), Cony (Paris, 1806), and Müller. See Fr W Schmidt, *De Heracleida Pontico et Diocorici Metempsychosis dialogis*, Breslau, 1857.

HERACLITUS of Ephesus, one of the most subtle and profound of the metaphysicians of ancient Greece, has only of late years had his true position assigned to him in the history of philosophy. To this the obscure and epigrammatic character of his style and the fragmentary condition of his works have in the main contributed, together with the fact that not only his immediate disciples but also his critics, including even Plato, have systematically laid stress upon those features of his doctrines which are least indicative of his real point of view. The true position of Heraclitus is that of the founder of an independent metaphysical system, which sought to get rid of the difficulty, so prominent in the Eleatic philosophy, of overcoming the contradiction between the one and the phenomenal many, by enunciating, as the principle of the universe, "Becoming," implying, as it does, that everything is and at the same time, and in the same relation, is not.

The descendant of a family of leading importance in Ephesus, Heraclitus was born about 555 B.C. His cast of mind was so intensely aristocratic that, filled with contempt for the councils and capacities of his fellow citizens, he made over the hereditary office of *basileus*, which had fallen to him in right of his birth, in favour of his younger brother, and betook himself to a life of solitary meditation. The date of his death was probably about 475 B.C.

To appreciate the significance of the doctrines of Heraclitus, it must be borne in mind that to Greek philosophy the sharp distinction between subject and object, which peculiarly modern thought has fostered, a consideration which suggests the conclusion that, while it is a great mistake to reckon Heraclitus with the materialistic cosmologists of the Ionic schools, it is, on the other hand, going too far to treat his theory, with Hegel and Jowett, as one of pure P-logism. Accordingly, when he denies the reality of Being, and declares Becoming, or eternal flux and change, to be the sole actuality, his whites must be understood to embrace not only the validity of the shallowest notion of being, except as the contradictory of that of not being, but also the physical doctrine that all phenomena are in a state of continuous transition from non-existence to existence, and vice versa, without either distinguishing these propositions or qualifying them by any reference to the relation of thought to experience. "Every thing is and is not," all things are, and nothing remains. With Heraclitus the principle of continuity is opposed to the principle of discreteness taught by the Eleatics, and consequently for him "Being and Nothing, as well as 'Union and Separation,' are logically and physically incapable of distinction. This being so, he naturally enough selects *Eiekt*, as according to him the most complete embodiment of the process of becoming, as the principle of empirical existence, out of which all things, including even the soul, grow by way of a *genesis* condescension, and into which all things must in course of time be again involved. But this is in itself a self that drives rational process, the harmony of which constitutes the law of the universe. Real knowledge consists in comprehending this all-pervading harmony, as embodying in the myriads of perception, and the senses are "bad witnesses," because they apprehend phenomena, not as its manifestation, but as "stiff and dead." In like manner *theoria* consists in the subordination of the individual to the laws of this harmony as the universal power wherein alone true freedom is to be found. "The law of things is a law of reason that men must men live as though they had a wisdom of their own." Ethics here stands in sociology in a close relation, similar, in many respects, to that which we find in Hegel and in Comte. For Heraclitus the world approaches most nearly to perfection when it is most akin to the *logos* upon out of which it was originally created, and as this is most so in death, "while we live our souls are divided in us, but when we die our souls are reunited to life." The doctrine of immortality comes prominently forward in his ethics, but whether this must not be reckoned with the figurative accommodation to the popular theology of Greece which pervades his ethical teachings, is very doubtful.

The only extant work, purporting to have been written by Heraclitus, which can be regarded as genuine, is the treatise *Tetralogoi*, which has come down in a fragmentary condition. It has been edited by Hermann Diels (*Die Fragmente der Vorsokratiker*, Berlin, 1901), and by Hermann Heitsch (*Die Fragmente der Vorsokratiker*, Leipzig, 1907). The *Tetralogoi* are in all probability spurious.

The school of disciples founded by Heraclitus flourished for long after his death, the chief exponent of his teaching being Cratylus. A good deal of the information in regard to his doctrine has been gathered from the later Greek philosophy, which was deeply influenced by it.

In his most complete exposition of his system as that of Lassalle (*Die Philosophie des Herakleitos des Dialektiker*, von Hermann Lassalle, Berlin, 1869) although his latest position is decidedly too strongly dominated by modern Hegelian conceptions, see also Hegel, *Geist der Philosophie*, Berlin, 1831, and Schelling, *Vorlesungen über die Philosophie der Sprache*, Berlin, 1809, and Schelling, *Vorlesungen über die Philosophie*, Berlin, 1809.

HERACLIUS (c. 575-641), emperor of the East, was born in Cappadocia about 575. He was brought into notice by his heading a successful revolt against the emperor Phocas in 610, when he usurped the usurper's throne. At that period the eastern provinces of the empire were being ravaged by the triumphant armies of Chosroes (Khosro) II., which in the first twelve years of Heraclius's reign continued their unrelenting progress to the Bosphorus and the Nile, pillaging Asia Minor and Syria, and reducing Constantinople to the utmost distress by cutting off its Egyptian corn supplies. In 618 the public distributions of grain, which had been carried on since Constantine had instituted them as a bribe to attract citizens to his new city in 330, were suspended, and the bankrupt emperor was heavily dissuaded

by the almost impetuous prayers of his people from quitting his capital in shame and fear for Caithage. Taking courage, Heraclius appears to have set himself to the task of reorganizing both state and army, a labour which had probably occupied him since his accession. He was menaced on the west by the fierce tribe of the Avars, who were casting longing eyes on the riches of the imperial city, but in 620 he succeeded in making a treaty with them, and intempered a human barrier against their further encroachments by inviting the Serbs and Croats to settle in the intervening regions, which they have never since left. In 621 Heraclius led an army into camp at Asas Minor, and devoted himself with a degree to the dulling of his inexhaustible troops. Every military manoeuvre, every useful exercise and even hardship, was ordered and shared by the emperor. He kindled the enthusiasm of his soldiers by his stirring words, and excited their admiration and affection by his deeds. Next year he led his forces against Persia, and within five years, in a series of brilliant campaigns that place him side by side with the greatest generals of the world, he overthrew the pride of that empire, drove its monarch a fugitive from his throne, and enriched his exulting troops with untold wealth. Success, the son of Chosroes, revolting against his unhappy father, put him to death in 628, and speedily made a peace with Heraclius, according to which the Persian empire was to be for ever limited to the frontiers mutually given up, and the true cross, carried from Jerusalem by the Persians, was restored to Christian hands. Heraclius returned in triumph to Constantinople, which had in his absence two years before successfully repulsed a combined assault by the Avars and Persians, and in 629 he proceeded to Jerusalem to restore solemnly the holy relic to its ancient place. But he was not long to enjoy the peaceful fruits of victory. A mighty power had been steadily growing up in the hot sands of Arabia, and was now coming to measure its strength with that of the Roman empire. In 632 the Mahometans invaded Syria, and, overthrowing the armies sent to oppose them, in six years they made themselves masters of the country. Egypt now fell before Islam, and in 640 that fair province of the empire was Mahometan. The people of Asia Minor alone successfully resisted the advancing Saracens. Heraclius seems meanwhile to have sunk into a sort of lethargy, as though his efforts in Persia had completely exhausted him. While his generals and armies were being cut to pieces he was engaged at Constantinople, whether he had retreated in 634, with speculative theological questions. In 638 his *Enchiridion* appeared, which, treated with the heroism of Monothelism, was probably drawn up by the patriarch Sergius. The energy of his earlier life never returned, and in 641 he sank under a long-continued disease. He had been twice married, the second time to his niece Martina, an illicit union which he compelled the reluctant Sergius to celebrate. His eldest son, Heraclius, succeeded him, taking the title of Constantine III.

The character of Heraclius is a curious riddle, which it is not easy to solve. Personally brave, and possessed of tried ability as a diplomatist and a general, in his latter years he passively allowed his empire to fall to pieces before his eyes,—presenting in the periods of his life a contrast that would almost seem to argue the possession of not merely contrary but contradictory qualities. But we must not forget that our information regarding the inner details of his latter reign is very imperfect, and that possibly there may be some reason, though hardly an excuse, for his conduct. It would have been better for his fame if he had died immediately after his Persian campaigns.

See Gibbon's *Decline and Fall of the Roman Empire*, Le Dieu's *Histoire des Bas Empires*, and the works of George of Zambes (cf. vol. v. p. 429).

HERALDRY

HERALDRY, though etymologically denoting all the business of the herald, has long in practice been restricted to one part of it only, and may be defined as the art of blazoning or describing in proper terms armorial bearings. It treats also of their history, of the rules observed in their employment and transmission, of the manner in which by their means families and certain dignities are represented, and of their connexion with genealogies and titular rank.

Particular symbols have in all ages been assumed by the various families of mankind, civilized and uncivilized. Such were the lion of the tribe of Judah, the S P Q R upon the standards of ancient Rome and the eagle surmounting them, the tattoo marks of the savages of America and the Pacific, the Danish raven, and the white horse of Saxony, which still remains carved upon the chalk downs of western England.¹ Heraldry, however, is a purely feudal institution, coeval with close armour, devised possibly in Germany, adopted and improved in France, Spain, and Italy, and imported into England by the Norman invaders and settlers. Its figures have little or nothing to do with the older symbols, though these have occasionally been incorporated into its charges, and an apparent connexion thus established between them. These symbols, as has been well said, were the precursors and not the ancestors of heraldic bearings. The supposed connexion, however, misled the credulous heraldic writers of the 16th and 17th centuries, and caused them to attribute coats of arms to the heroes of sacred and profane history, who were certainly as ignorant of heraldry as even was Adam of genealogy.

"Arms" or "armoures," so called because originally displayed upon defensive armour, and "coats of arms" because formerly embrodered upon the surcoat or camic worn over the armour, are supposed to have been first used at the great German tournaments, and to have reached England, though to a very moderate extent, in the time of Henry II and Count de Lion. To "blazon," now meaning to describe a coat of arms, is the German "blasen," to blow as with the horn, because the style and arms of each knight were so proclaimed on public occasions. The terms employed in heraldry are, however, mostly French or of French origin. Though now notions of form and ceremonial, and subject to the smile which attaches to such in a utilitarian age, armorial bearings were once of real use and importance, and so continued as long as knights were armed in plate, and their features thus concealed. As that time lapsed was recognized in the field by their insignia alone, and these—both figures and colours—became identified with their fame, from personal became hereditary, were subject to certain rules of descent, and to the laws of property and the less certain rules of honour.

Froissart mentions a case in which a knight of the Scopee family could with difficulty be restrained from putting to death a prisoner because he wore the same bearings with himself. The last De Clare owed his death on the field of Bannockburn to his having neglected to wear his *cotte d'armes*, had he been recognized, his great value as a prisoner would have saved him. Also the loss of the battle of Barnet was in part attributed to the similarity between the royal cognomance of a son and that of John

de Vere, a stat with streamers,—Warwick charging Oxford by mistake for the king.

The best if not the only absolutely safe evidence for the origin of armorial bearings is that afforded by seals. Seals were in common use both before and after the introduction of armorial bearings, and they are not so likely as rolls of arms or monumental effigies to be the work of a later age. These are said by Concelles to be extant, appended to charters of 1030 and 1037 A.D., two seals of Adalbert, duke of Lorraine, which bear on a shield an eagle with wings closed. This however wants confirmation, but Anna Comnena, describing the shields of the French knights who visited Constantinople about 1100, gives their surfaces as of metal only, polished but plain, nor have any decided traces of arms been discovered among the early ones. Louis le Jeune, who seems first of the French kings to have used the fleur-de-lys, caused it to be represented in gold over the azure mantle and chausses worn by his son at his coronation. Also, in 1180, he seals with a fleur-de-lys, but it is placed in a cude, not upon a shield. Blanchinot, two seals of Philip, count of Flanders, one plain, in 1157, and another in 1164 charged with a lion, then subsequent bearing. Seton mentions the seal of John de Mundegumbi in 1170 as bearing a fleur-de-lys, which, like that of Louis, has two intermediate flower stems, as seen on Florentine coins. He also gives the seal of Falconer (1170) as bearing a falcon, and that of Corbet bore two ravens perched upon a fleur-de-lys, while his brother bore them upon a tree. This indeed was at a period when fleurs-de-lys, stars, and various animals were commonly represented as mere ornaments on seals, but the peculiarity of the instances named is that the falcon and the raven, like the fleur-de-lys of France, were afterwards the heraldic bearings of those families. The seals of the close of the 12th century, though not generally heraldic, certainly betray many of the elements of heraldry. No doubt, when once introduced, armorial bearings were felt to supply a real and serious want, and came rapidly into use, but Waco, the poet of the reign of Henry II, although he tells us that

"N'a une honte home no Baron,
Ki n'ait le li von gonfoun,
U gonfoun u alre ensengne,"

can scarcely be seriously held to mention armorial bearings.

It is uncertain at what period armorial bearings found their way into England. The Conqueror and his successors certainly did not use them, they did not appear upon their seals, nor so they shown upon the banners of the Bayeux tapestry. The monk of Malmesbury, probably a contemporary, describes Henry I, upon the marriage of his daughter to Geoffrey of Anjou in 1122, as hanging about the bridegroom's neck a shield adorned with small golden lions, "*leoneculos aureos*," and making mention of a combat in which Geoffrey was engaged, he describes him as "*pictos leones praefores in clypeo*." It is true that the number, attitude, and position of these lions on the shield are not specified, but considering that not long afterwards two lions became the arms of Plantagenet, and so of England, thus may fairly be taken as their introduction. Stephen is said to have used a centaur, Sagittarius, as an emblem, because he landed in England when the sun was in that sign, but on his great seal his shield is quite plain, save a ridge down the centre, evidently a part of its construction. On the seals of the Conqueror, Rufus, and Henry I, only the hollow or under side of the shield is shown, so there probably was no design upon the front. There is no seal of Duke Robert, but William, earl of Flanders, his son, shows a

¹ The subject of ancient and especially of Greek "heraldry" is discussed by Curtius in a learned and interesting paper "*Wappengebrauch und Wappentypen im Alterthum*" in the *Abhandlungen der Königl. Akad. d. Wissenschaften zu Berlin* (1874). See also article *Grav.* vol. x. p. 158.

plain shield on his seal. His monumental effigy (1198) bears a large pavese-shield, and upon it an escutcheon, apparently a highly ornamented clasp. The seal of Henry II also shows the hollow of the shield. The first great seal of Richard I bears a lion rampant, who from his position may be inferred to be fighting with a similar lion upon the surmount and concealed half of the shield, blazoned in a MS cited by Mr Wey as "two lions combatants."

Up to this time the king, though represented on horseback and in full armour, have the face uncovered, and therefore their persons would be known. The seal of Richard I in 1189 shows a close helmet, and upon the shield two lions passant guardant in pale, "leones leopardis," as they were then or soon after called. On a later seal, after his return from captivity in 1194, Richard added a third lion. John, while earl of Mortmain, sealed with two lions, but his seal as king bears three, and the coat has so remained. That the two lions were more than a mere ornament is evident from their having been adopted by John's natural son, Richard de Warren, who seals with two lions passant guardant. The seals of the great barons show the growth of the practice. Richard, constable of Chester, contemporary with Stephen, bears a shield covered over with small plates, regulated, like his armour, but Stephen, earl of Richmond, as early as 1137, seals with seven fleurs-de-lys, a very early heraldic seal. Walrein, earl of Moulain (died 1166), also used an heraldic seal. Duchesne gives a seal of Boucard de Montmorency (1182), a contemporary of Louis le Jeune, with a cross between four alerions on his shield, and another in which the cross is charged with roundels. Mathieu, his son, seals also with the cross and alerions, which had evidently become, as they remained, hereditary. In England, William, earl of Essex (died 1190), seals with the escarbuncle of his family. In 1187 Gervase Pagnol, a great Anglo-Norman baron, seals with two lions passant, which his family continued to bear.

With the 13th century arms came rapidly into use. The second seal of Mathieu de Montmorency in 1200 has them introduced upon his horse's furniture, but this practice does not appear upon the seals of the kings of England until the second seal of Edward I. Baldwin de Bethune, earl of Albemarle (died 1214), sealed with three martlets in chief, and many other early examples of regular heraldic seals occur at this period attached to extant charters. The earliest roll of arms is of the reign of Henry III., of a second of the same reign a copy is preserved in the Harleian collection, and a third, in the next reign, is the roll of Carlarivock, 1300 A.D. So that for the reign of Henry and his son the evidence for armorial bearings is copious and excellent. Other rolls exist carrying the practice through the 14th and 15th centuries, before the middle of which there is no known work on heraldry, nor any trace of heraldic regulations save what may be deduced from recorded practice.

Coats of arms were not at first strictly hereditary, nor even always permanent in the same person. Thus William de Ferrars, 6th earl of Derby (died 1246), seems to have borne "argent, 6 fers de cheval, or hoise shoes, 3, 2, 1, sable." William, his son, in consequence of a match with Pevenell, who bore "vair," changed his bearing to "vair, or and gules, on a border azure 8 hoise shoes argent." Robert his son, 8th earl (died 1278), dropped the hoise shoes, and bore "vair, or and gules."

"Ferrars has tobard with redi vair spread."

After the match with Quincy, the Ferrarses laid aside their own coat and bore that of Quincy, "gules, 7 mascles conjoined 3, 3, 1, or." Their male line through a younger branch, — the Ferrarses of Baddeley-Clinton, — commemorates these various changes by bearing "quarterly, — (1st) vair, or and gules, (2d) sable, 6 hoise shoes, 3, 2, 1, argent, (3d)

gules, 7 mascles, 3, 3, 1, or, a canton cinnme." Hugh Lupus, earl of Chester (died 1101), is fabled to have borne a wolf's head, and not improbably his surname arose from some such emblem. Richard, his son, is said to have borne "azure, semee of croissants or, a wolf's head erased argent." Ranulph Meschines, 3d earl (died 1128), was sister's son to the first earl, and to him is assigned "or, a lion rampant gules." Hugh Cyfehuoc, 5th earl (died 1180), certainly bore "azure 6 garbes of wheat, 3, 2, 1, or," and Ranulph Blondeville, his son, bore "azure, 3 garbs or." With him the line failed, but as the wheat sheaf is a common Cheeshire bearing, it is probable that arms came into general use in the palatinate in the time of the last two earls.

St Nicholas Cairn (died 1283) seals with a tricornate lion, but at Carlarivock in 1300 is found with a

"Bannet et juncat bene passibili,
O tunc passant lions de vrbis,

the arms of the Carews of our day. The fess and label of Saher de Quincy, earl of Winchester, in 1170, were changed by Roger his son for the mascles by which they were best known, and which he repeats upon his housings. The fact is that, at the close of the 13th century, arms, though on the whole hereditary, had not quite acquired that fixed character that belonged to them half a century later. That the changes were accidental rather than the rule is, however, clear from the roll of Henry III., and from the arms of the forty great barons which he caused to be painted on the walls of Westminster Abbey, almost all of which, so far as they are on record, are the same with those borne or quartered by their representatives. There exist also in England a few families of Norman origin, the period of whose arrival in England is known, and whose arms are the same with those of the present stock in the parent country. Such are Harcourt of Ankerwyke and D'Aubigny, who therefore bore their arms before the separation from Normandy under Henry III.

Early bearings were usually very simple, the colours in strong contrast, and their form and outline such as could readily be distinguished even in the dust and confusion of a battle. They are mostly composed of eight lined figures known in heraldry as ordinaries. The favourite beast is the lion.

The earliest and most valuable records relating to English armorial bearings are undoubtedly the rolls of arms of the reigns of Henry III. and the first three Edwards, which have been well edited by Sir II. Nicolas. That of Henry III. known as Glover's roll, drawn up between 1243 and 1246, describes or blazons 218 coats of arms, and therefore shows very sufficiently the heraldry of the period. Of these coats nearly one half are composed solely of the ordinaries and subordinaries, and other simple lines and figures. About two score of them exhibit lions, chiefly rampant, and leopard, a form of the same animal. The only other beast is the "teste de sanglier," borne by Swinburne. Of birds there are but the eagle and the jayrager, several martlets, and single examples of the raven, the cock, the heron, and the hoivole. The lucer or jake is the only fish. The cinquefoil and sexfoil, the fleur-de-lys, the rose, and the wheat sheaf, used very sparingly, represent the vegetable world. For the rest there are annulets, manacles, crescents, estoiles, escallopes, fers de cheval, mullets, and water budgets. There is one ray of the sun, and one whirlpool.

The coat of Mortimer "barre, a chief pale, a corner geronne d'or et d'azur, a ung sceulleon d'argent," — or, in modern terms, "barry, a chief pale, its corner gyronny or and azure, an escutcheon argent" (fig. 63), — is the only one at all of a complex character, and this is composed of ordinaries and subordinaries, and though many of the ordinaries bear the smaller charges, or are placed between them, there are very few examples of an ordinary so charged also.

placed between charges, a common usage in later coats. An exception is Chaudois, who bears three eskules on a pile, which again is placed between six others, but this stands alone.

The roll of Edward II. bears 557 coats of the banners of England, so that the use of arms had increased considerably. The lions have risen to 225, the eagles to 43, and there are 102 crosses of various kinds. Of new beasts, fabulous or real, there are the griffin, the wyvern, the stag, wolf, goat, and greyhound, of new birds, the falcon, of fishes, the dolphin. Of other objects the additions are the milliard, buckle, coveined cap, chaplet, gambellet, arrow, trumpet, hammer, battle-axe, palmer's staff, pot, winnowing fans or vains, pens, ensuiler, and chessrook. The character of the arms remains very simple, and the blazon employed agrees in the main with that still in use, and is in general perfectly intelligible. These rolls give various examples of changes of coats, either altogether or by the introduction of a difference to distinguish members of the same family, and it is observable that when the figures are altered the colours are usually adhered to, as though it were considered undesirable to change them. Thus Gilbert de Sognave (died 1254) bore "sable, 3 gables argent." Of his grandsons John and Nicholas, John bore the paternal coat, but Nicholas, at Oselewicock, had exchanged the gables for lions. This afterwards became the family bearing of the noble lion rampant argent, crowned or, the colours being retained.

No sooner had the great barons assumed arms for themselves than they began to grant them to their followers. Arms so granted commonly bore some resemblance to those of the grantor, and hence certain charges prevailed in certain districts. Thus the cleveon of De Clare was common in South Wales, in the Monarchs of Gloucester and Clare, and about Tonbridge. The garb or wheat-sheaf was found in Chesham, the cinquefoils of the Bellomonts in Leicester shire, the annulets of Vipont in Westmoreland, the lion all over England, and the treasure in Scotland, both from the royal arms. Some of those grants remain, others can with certainty be traced. Stephen Cuzson, who held under the earls of Derby, bore "vair, with a border of 8 popinjays argent," and Richard, his brother, bore "vair, on a fess 3 hussar-shoes." Hubert, earl of Kent, bore "7 lozenges vair," and Anselm de Guse, on taking under him land in Berks and Gloucester, assumed the same coat, with the addition of a canton or, charged with a mullet sable. In 1310 Robert Moles granted to Robert de Courby and his heirs the arms "d'argent, over un salient engailé de sable," which he himself had inherited from Baldwin de Mancrois. In 1376-7 William, baron of Greystock, who bore "barry of 6 argent and azure, 3 chaplets gules," granted to Adam de Blencowe and his heirs for ever "un escutcheon sable with a bord clostret [or bordered] argent and azure, with 3 chaplets gules." In 1391-2 Thomas Grenville granted to William Moigno his heirs and assigns, "argent, on a cross azure 5 garbs or," which, as cousin and heir, he himself had inherited from John Beaumays. Finally, in 1442, Humphrey, earl of Stafford, who bore "or, a chevron gules," granted to Robert Whighaveas "un escus d'azure, 3 quatuor points d'or, quatre chevrons de gules," to him and his heirs of Moigno,—in modern terms "azure, a cross quarter-pieced or, on each limb a chevron gules." A coat of arms was not only hereditary, subject to certain heraldic customs, but could be willed or granted away, wholly or in part, like chattel property.

The crusades, by bringing together soldiers of different nations, tended to produce a certain assimilation in their heraldry, but their influence upon the arms themselves has been exaggerated. The stories as to bearings adopted to commemorate feats of arms in Palestine are mostly

inventions. The cross no doubt was a crusading bearing, but it was so because it was the emblem of Christianity, and primarily popular as such. The stars, torteaux, water budgets, and other charges attributed to the crusaders, were of earlier date and of independent origin. There is no evidence that the crosses patée of the Berkleys, or the crosslets of Beauchamp, Clinton, Windsor, and Howard, were added to their simpler bearings in token of services in the Holy Land. The star of De Vere, always attributed to an adventure there, was evidently a mark of cadency, adopted by Robert de Vere, brother of Albemarle, 2d earl of Oxford. The fact appears to be that most of the additions to or alterations in the earlier coats of arms were made for some genealogical reason, to commemorate a match with some great family or to distinguish between the several branches from the parent tree. After, usually long after, the period of the crusades, arms were invented for "fabled knights in battles feigned," and but few of the Saracens' heads which figure so prominently in many coats of arms are contemporary with any Saracenic war.

The diversion of the tournament did even more than actual war to promote the glories of heraldry. On these occasions the presence of spectators, and especially of ladies, encouraged all sorts of heraldic display. At a tournament at Calais in 1381 Richard Beauchamp, earl of Warwick, one of the most accomplished knights of the reigns of Edward III., Henry IV., and Henry V., vied with other knights on shields these several coats of arms, as representing three several knights who professed to be ready successively to meet all comers. Three French knights appeared to the challenge. Against the first the earl came forth as the green knight with a black quarter, bearing "silver, a manich gules," the arms of De Tony, a maternal ancestor, and so overcame his adversary and retired unknown to his pavilion. On the second day he appeared as the green knight, and bearing "silver, two bars gules," the arms of Mauduit of Hainlape, another ancestor, he met a second knight with equal success. On the third day he appeared in his proper person bearing the arms of Guy of Warwick and Beauchamp on his shield, and those of De Tony and Mauduit on his caparisons, and thus with great honour won the third day also.

The shield, as the most obvious piece of the defensive armour, was that upon which arms were first displayed. The Norman shield was of wood covered with hide, and clamped and stiffened in a fashion which is thought to have given rise to the first simple bearings. It was 3 to 4 feet long, pointed below, and 18 inches broad. This shield is common on early monumental effigies armed in chain mail, and it is unusual to find it with armorial bearings. It was succeeded by the small triangular heater shield, and that, in the reign of Edward III., by a somewhat larger and full bottomed shield, which by degrees ceased to be used in war, and became more and more an architectural ornament. The arms were also displayed upon the breast-plate, and upon the camise or surcoat that covered the armour, and were repeated upon the housings of horses both before and behind the saddle. When the Comte d'Artois fell at Damietta, the Saracens showed in triumph his "cotte d'armes toute dorée et flam de-luée." The emperor Henry of Luxembourg is described in the *Chronicle of Flanders* as bearing "an eagle noir, sur un torsele d'or qui pendoit jusq' a mi-jambe." Sir Alexander Neville appeared at Haddon Hall in a surcoat of his own arms, the quarters filled up with the arms of his friends. The flag effigy of William de Wyndesore at Westminster is decorated with small representations of his arms on various parts of his dress and weapons. An actual remnant of the richly embroidered surcoat of William de Ponthus, earl of Albemarle (died 1261), is still preserved, and has been engraved in the

As chasologia It was against the embroidery of the surcoat that the severe sumptuary enactments of Richard and Philip Augustus were mainly directed.

The importance attached to armorial bearings is strongly shown in the uses to which they were applied. A sovereign who wished to assert his claim to a kingdom placed its arms upon his shield. In 1479 when Alphonso of Portugal resigned his claim to Castile, he was required to lay aside its armorial ensigns. It appears that when Edward III. assumed the French lilies, he at first did so simply as representing his mother, who was an heiress, and placed her arms in his second quarter, when, however, he claimed the kingdom of France in her right, he removed the lilies to the first quarter as representing the more important kingdom. A grant of arms at the hand of a sovereign had great value. Among the more solid bribes which Louis XI. bestowed upon the courtiers of Edward IV. occurs a grant of three fleurs-de-llys to a knight of the Croket family. Thus also when Juan de Olieta captured Francis I. on the Terno, he was rewarded by a grant of arms from Charles V., though of so complex a character as to do little credit to Spanish heraldry. In later times John Gibbon, the heraldic author, having a quarrel with two maiden ladies of his name, obtained a licence to convert the scallops in their common coat into the black balls called ogresses,—a most heraldic revenge.

Armorial bearings were largely painted, enamelled, and embroidered upon personal ornaments, furniture, and weapons. The sword of Edward, prince of Wales (died 1483), is a curious example of this, it bears on its pomel the words "avos fozes" and five shields—(1) England, (2) the duchy of Cornwall, (3) England and France with a label, (4) Mortimer quartering Ulster, (5) the earldom of Chester. In the middle is the cross of St. George. The citizens of London were bound to provide their banners, banners, Lord Fitz Walter, with "a saddle with his arms," and the seal of one of that family, about 1300, shows the arms upon the back of one of his war saddles. The seal of Sir Hugh de Despenser, (1392) also shows his arms. Various bequests of plate and furniture with arms occur in the 14th century. In 1368 William, Lord Ferrars of Groby, bequeathed his green bed "with his arms thereon, and his furniture bearing the arms of Ferrars and Ufford, impaled." In 1380 Edward Mortimer devised "à nos tres chier freres John Gubert, eveque de Hereford, une plate de argent upon espices et enamillés over les armes de Mortimer en la face."

Richard, earl of Arundel, in 1392, bequeathed a canopy of the arms of Arundel and Warren quarterly. In 1399 Eleanor Bohun, duchess of Gloucester, had a psalter with her father's arms upon the clasps. In the Decorated and Perpendicular styles of a chaste and simple arms are common ornaments. Those of benefactors were set up in church windows in glass, and those of a family in their houses. In the Scope roll is a list of sixty-six churches in which the Scropes arms were set up, and the histories of Dugdale and Burton show us that nearly every church in Warwickshire and Leicestershire had a multitude of arms on its windows. Those still remaining in the east windows of Bristol cathedral are early and good examples of the arms of great barons, Berkeley, Clare, and Warren. They are also seen upon floor tiles of the same period.

As arms became hereditary, and then use ceased to be confined to the battle-field, but was largely extended to seals and ornaments, it was natural that some notice should be taken of the arms of families, and that the wife's coat should be combined in some way with that of the husband, especially when she was the last of, and represented, her family. This seems first to have been managed by giving the wife a separate shield. The kings of France so bore

the arms of Navarre after the marriage with the heiress of that kingdom. Another very early plan was to form a composite coat. Thus the old coat of Willoughby was fretty, but on their marriage with Dec of Evesby they adopted the coat of Dec, and Sir John Willoughby (13th Edward III.) bears the cross mollet of Dec, but the wings of his crest are fretty for Willoughby, and on either side is a buckle taken from the arms of Roscelin, his wife. Rose of Kilravock bore "or, 3 water budgets sable," but on a marriage with the heiress of Chisholm they added "a boar's head couped gules" from her arms. So also Halibuton of Pitou, who bore "or, on a bend argent 3 longears of the field," after a marriage with another Chisholm heiress, added to their coat "3 boars' heads erased sable." Dobun, who bore "azure, a bond argent, couped or, between 6 lions rampant of the third," is thought to have added the bend on the occasion of a marriage with Maud, daughter and heir of Milo, earl of Hereford. As this, however, led to complexity and indistinctness in the bearings, and the introduction of a second shield was obviously inconvenient, the method of impalement was devised, by which the sinister half of the shield was appropriated to the lady's arms, at first under the process known as dimidiation. When, however, the lady was an heiress, a different plan was adopted which ultimately led to the queuing on the marshalling of many coats in one shield, a practice, when restricted to any extent, quite inconsistent with the original use of coat armour. This also led to a corresponding alteration in the shape of the shield, which was expanded to contain the arms of each heiress who had married into the family, together with such other heiresses as her family had previously been allied with, so that when a Percy heiress married a Seymour, she added her heiress ancestors' arms with her own arms to those of her husband, expanded in a similar fashion by the previous matches of his family. Thus the great shield of a family became a compendium of the family pedigree which, to those who could read its language, conveyed a considerable mass of semi-historical information. The defect of this system was that it only took account of heiresses, and did not provide for the purity of the whole descent, so that under it the children of a man of no birth who married a great heiress, would display all her quarterings, and no account would be taken of the absence of any on his side, and further, if it happened, as was usually the case in the last century with the Wodeys of Rodney stoak, that a family, though ancient, had never intermarried with an heiress, they could display no quarterings.

In France and Germany and to some extent in Scotland a far more perfect system was pursued. The civil logical system included the arms of every ancestor and ancestress, whether an heiress or not, thus one generation gave two coats, two generations four coats, and so on. "Seize quartiers" gave evidence of pure blood for four generations, and thirty-two quarters, the qualification for a canon of Strasburg, for five.

As the combinations out of which the early coats were formed were limited, it occasionally happened that two persons of the same nation bore the same arms, and thus gave rise to disputes which, as matters connected with military discipline, came under the jurisdiction of the earl marshal. One of the earliest of these disputes is mentioned in the roll of Calverley—

"Le beau Bryan de Fitz Aleyn,
De contesie, et de honneur poyne,
Fu o brames barons
De or et le goulz lian puce,
Dont le challenge estoit le poynt,
Fur entre lui et Hue Poynt,
Ki portoit del or plus moyn,
Dont merveille nest memoire et memoire."

Cases of a similar character were decided between

Harding and St Leo in 1312, Warbinton and Gorges in 1321, and Sytylet and Fakenham in 1333, when Sir William Fakenham disputed the arms, "le champ de duse basist argent et azur, supportez de cinq ocochons salios, charges ovesque tant de Lyons pumeis rampant inoeneés gales." They were adjudged by a commission to Sytylet Hugh Malby and Hamon Beckwith had a similar dispute in 1330. But by far the most celebrated dispute of this nature arose in 1384 between Sir Richard Scrope of Bolton and Sir Robert Grosvenor, for the right to bear the arms "aune, a band or." The greatest men in the country, including John of Gaunt, gave testimony on one side or the other, and it was shown that each family had used the coat beyond the memory of man. It was finally adjudged to Scrope, and Grosvenor was directed to bear "les ditz armes ove une playne bordie d'argent." Grosvenor, however, declined to accept the arms so differentiated, and assumed "aune, a gaub or," retaining his colour and making his connection with the old arms of Chester. It was proved, incidentally, that an ancestor of Grosvenor's had granted his coat, with a difference, to William Coton of Coton. It is remarkable that both disputants are still represented in the male line, and continue the arms as then settled. Both families had previously had disputes with other parties, and the Scropes long afterwards had a quarrel with the Stanleys for the right to bear the arms of the Isle of Man. The matter was compromised by Edward IV. The Hastings and Grey de Ruthyn case, which rises to the rank of a tragedy, illustrates still more forcibly the value attached to a coat of arms. On the death, childless, in 1380, of John de Hastings, earl of Pembroke, a dispute arose for his heirship between Reginald Grey, his heiress's son, and Edward Hastings, the heiress's male and of the name, but of the half-blood. A court military decided in favour of Grey. Pending the trial Hastings had ceased to difference his arms as a cadet, and assumed then unbroken. He was, however, ordered to bear them with a label, and for continuity was imprisoned for sixteen years. A suit for arms was decided as lately as 1720 in Blount *versus* Blount, in the earl marshal's court.

The same necessity that made it important to prevent the use of similar bearings by different families in the same country made it also necessary to distinguish between the bearings of different members of the same family, all of whom had a right to the paternal coat. As this right was strongest in the eldest son he alone bore the paternal arms unaltered (in French he aldry "sans bisuise"), and the other sons were obliged to introduce some sufficient change, called in heraldry a "difference." This was at first managed by inverting the colours or substituting one ordinary or one inferior charge for another, as a band for a fess, martlets for mullets, and the like, and sometimes by the use of a coat compounded of the paternal bearing with that of an ancestor. A multitude of these early differences occur in the rolls of Henry III and Edward I, and in various early lists of arms. The family of Grey, always numerous, differentiated their cadets in at least fourteen different ways, almost all preserving in some tangible form the paternal coat, and thus was also the case with the very numerous family of Bassett. Generally no rule is followed, save that on the whole some reference is retained either to the charges upon, or the colours of, the paternal coat. Very frequently, even in the earliest times, the eldest son differentiated his father's coat by a label. In the roll of Henry III the label occurs fifteen times, though not always as a difference. Gradually, however, it came to be used almost entirely for that purpose, and finally a set of marks, called cadency, were devised for each of the sons, the label being the mark of the eldest during his father's life.

All these rules and alterations were, however, the growth

of a later age, and came into use as the bold and simple heraldry of the 13th and 14th centuries began to be overlaid with florid fancies. So long as heraldry represented a real want, its expressions were simple and intelligible, but as "villanous salpêtres" came into use and closed helmets were laid aside, and as skill and strategy rather than personal valour became the attribute of a leader, armorial bearings fell into disuse in war, and were no longer worn upon the person, or upon the horse's trappings. But though armorial bearings ceased to be of actual use, they continued to be emblems of rank and family, and a mark of gentle blood. They became, however, exceedingly and often absurdly complex, partly because simplicity was no longer necessary, and partly because it was scarcely practicable, owing to the enormous increase in the number of the gentry, which produced a demand for new combinations.

The glories of heraldry reached their zenith in the reign of Richard II, with "youth at the plow and pleasure at the helm" of the vessel of the state, but it was not till the reign of Richard III that it was thought necessary to place under specific control the whole heraldry of the kingdom, and thus, in close imitation of the example of France, was done by the incorporation of the heralds into a college placed under the presidency of the earl marshal.

The office of the herald as the messenger of war or peace between sovereigns or between contending armies in the field is of far earlier date than the introduction of armorial bearings, but as those came into use they were gradually placed under his charge, and he took his specific name sometimes from that of the noble or lord who employed him, sometimes from one of his ensigns or titles of honour, and sometimes from one of his badges or cognizances, which the herald wore embroidered upon his dress and by which he was known. In the pages of Froissart and other chroniclers frequent mention is made of heralds at arms and their attendants the pursuivants, and we read of Somerset and York, Windsor, Chester, and Lancaster heralds, Clancour, Arundel, Flou-de-Lys, and Leopard, and of pursuivants, Antelope, Blanch Lion, Falcon, Portcullis, and many more. At an early period the principal heralds, and especially those attached to sovereigns, were called kings at arms, and as early as Edward I an officer, called from his jurisdiction, Noctoy, was placed in charge of the heralds north of the Trent. It is probable that a herald was always attached to each order of chivalry, as Tossou d'O to the Fleeces, and Garter to the chief English order. Garter, however, was only officially appointed by Henry V, when he seems to have been recognised as the principal king at arms—"Principalis rex armorum Angliænoium." At the institution of the college, or soon afterwards, it was decided that six officers should be appointed, principal king at arms, Norroy and Clancour, provincial kings north and south of Trent, six heralds, Windsor, Chester, Lancaster, Richmond, Somerset, and York, and four pursuivants, Rouge Croix, Blue Mantle, Rouge Dragon, and Potcullis, who constitute the present establishment, though some special officers have since been appointed, as a king at arms to the revived order of the Bath, and some others, not members of the college.

It became the duty of the new incorporation to take note of all existing arms, to allow none without authority, and to collect and combine the rules of blazoning into a system. To effect a supervision of the armorial bearings throughout the kingdom, it was necessary to visit the several counties. Such a commission of visitation seems to have been issued by Henry IV. as early as 1419, but the first regular commission acted upon was issued by Henry VIII., 1538-9, and the last early in the reign of James II. The visitations were taken about every thirty years, and for contemporary events are most valuable records. The provincial king, either

personally or by deputy, visited the capital town of each county in his division, and summoned the surrounding gentry to record their pedigrees, and show a title to their armorial bearings. The earl marshal's court survived the fall of the house of Stuart, and a few causes relative to a right to particular arms were decided in the course of the last century, but its powers fell into disuse, and not long since it was finally abolished, and with it fell any pretence on the part of the college to regulate, by compulsory authority, the heraldry of the kingdom. At present, however, notwithstanding the democratic tendencies of the age, armorial bearings are in greater demand than ever in England, and more or less coveted in the United States, and a good deal of the proper business of heraldry is still transacted within the college of arms, and a good deal more, irregularly and improperly, outside it. A considerable number of persons still bear arms derived from an ancestor who bore them before the institution of the college, others bear them under grants and patents from that body, and others still more numerous, who or whose fathers have risen from obscurity, have assumed arms according to their fancy, or under the unadvised advice of some silversmith or finder of arms. The Smiths, said a distinguished member of the family, had no arms, they sealed their letters with their thumbs. It is to avoid so inconvenient a signet that the new men have recourse to the demi-lions and demi-griffins now so much in vogue, and possibly because they are not aware that Garter and his colleagues are still willing to grant arms, crest, and motto, on terms within reach of almost every aspirant to chivalry.

There is no college or corporation of heralds in Scotland or Ireland, but in Scotland heraldry has been to the full as much considered, and at least as well regulated as in England. "Lyon-king-at-arms," "Lyon sex armorum," or "Leo fecialis," called from the lion on the royal shield, is the head of the office of arms in Scotland. When first the dignity was constituted is not known, but Lyon was a prominent figure in the coronation of Robert II. in 1371. The office was at first, as in England, attached to the earl marshal, but it has long been conferred by patent under the great seal, and is held direct from the crown. Lyon is also king-at-arms for the national order of the Thistle. He is styled "Lord Lyon," and the office has always been held by men of family, and frequently by a peer. His powers have been declared by statute, and extend to fine and imprisonment. He is supreme in all matters of heraldry in Scotland. Besides the "Lyon deputy," there are the Scottish heralds, Islay, Rothesay, Macchamont, Albany, Ross, and Snowdown, with precedence according to date of appointment, and six pursuivants, Kintyre, Dingwall, Caithness, Bute, Ormond, and Unicorn. Herald and pursuivants are appointed by Lyon.

In Ireland also there is but one king-at-arms, Ulster. The office was instituted by Edward VI. in 1553. The patent is given by Rymae, and refers to certain emoluments as "parochia officio ab antiquo spectantibus." The allusion is to an Ireland king-at-arms mentioned in the reign of Richard II. and superseded by Ulster. Ulster holds office by patent, during pleasure, under him are two heralds, Cork and Dublin, and four pursuivants, Athlone, and St. Patrick Nos. 1, 2, and 3. Ulster is king-at-arms to the order of St. Patrick. He held visitations in parts of Ireland from 1569 to 1590, and these and other records, including all grants of arms from the institution of the office, are kept in the Birmingham Tower, Dublin, under the charge of the present most courteous and learned Ulster, Sir B. Burke. The precedence of the three chiefs has been the subject of dispute, but is now generally arranged, Garter being followed by Lyon, and he by Ulster.

Heraldry should be studied with reference to the period

in which it was a useful art, and in the simple examples of the 14th and 15th centuries. Before that period it was in a changing and elementary state, after it, it became merely ornamental, and its examples are complicated and debased. In a general treatise on the subject notice must of course be taken of the later as well as the earlier conditions of the art, but the greater number of the illustrations in the following pages are taken from the earlier and best examples.

A curious evidence of the vitality of heraldry, and of the desire of all mankind for ancestral distinctions, is afforded by its extension among the republics of the New World. The United States boast some excellent genealogical societies, and a great and very general desire is shown by individuals to trace their pedigrees to the stocks of the Old World, and to assume the arms proper to their name. The national emblem of the stars and stripes, now so widely and honorably known throughout the world, has been traced back to the paternal coat of the first and greatest president, George Washington, whose English ancestors bore "argent, 2 bars gules, in chief 3 mullets of the second." In Canada, Australia, and other English colonies, the assumption of arms by individuals and by the community is not less general, and the republics of South America, of Spanish origin, almost all have adopted coats of arms. The Peak of Tenerife, the Beave, the Red Indian, contribute to the list of charges, and the clear firmament of Chili is indicated by a star. "Coupé d'azur sur gules, à une étoile d'argent en alme."

DIVISIONS OF ARMS

Arms or bearings may be conveniently divided into those of dominion, of a community, of office, of consanguinity, family or paternal arms, and arms of alliance. To these may perhaps be added arms of attribution. There is also another division, or rather peculiarity, called canting arms, of which many of the former divisions present examples.

1. *Arms of Dominion* are those of a kingdom or a feudal lordship. The origin of such arms is often obscure. Those of the Isle of Man are three legs conjoined in triangle at the thigh (fig. 116), probably borrowed from the cuillom of Sicily, the ancient Trinacra, found upon Greek vases. The Irish harp is an emblem probably allusive to the instrument of Brian Boromha. The origin of the lion of Scotland is the obscure, and of the treasure equally so, though fabled to be

"Fist by Achais borne."

Not unfrequently the arms of kingdoms were those of an early sovereign, adopted by succeeding dynasties to the exclusion of their own coat. The lions of England were certainly personal to the Plantagenet kings, if not to Henry I., but they have become national to the exclusion of the arms of the Tudors, Stuarts, Brunwicks, and Saxon dynasty, just as neither the arms of Babel, Buce, nor Stuart ever became the arms of Scotland. The lion rampant, arms, crowned gules, so long borne by the head of the German empire, belonged originally to the house of Hapsburg, and was not used by such of the early emperors as were not members of it, and the bend and alions of Lorraine only became a part of the arms of the empire after the marriage of Francis of Lorraine with Maria Theresa. It seems indeed to have been the custom of elected sovereigns, as those of the empire and of Poland, to place their paternal arms on a shield of pretence over those of the dominion. Cromwell so placed his arms over those of the commonwealth, and William of Nassau over those of England, but they disappeared with the individual who introduced them. On the other hand the arms of kingdoms and lordships are sometimes continued to be used as personal arms by the descendants of their former lords. The great shield of Mary of Burgundy quarters the arms of a number of

duchies and provinces. Simon de Montfort thus used the arms of the Honour of Hinkley. Richard de Montchomer (who married the countess of Gloucester, and was, by courtesy, earl of that name) at Caerlwyroek, while he bore on his shield his own arms, "or, an eagle displayed vert," on his banner displayed "or, three chevrons gules" for the eridom. So also Humphrey, duke of Gloucester, (died 1446), used on one of his seals the three fusils of Montacute, because he held lands which belonged to that barony. The *Book of St Albans* says that, if the king grant a lordship to a youngman entitling him to bear arms, he may take those of that lordship.

Under this head may be described the armorial shield of Great Britain (fig. 1). The arms, gules 3 lions passant in pale or, are for England, and are so borne by the kings of England till the reign of Edward III., who in 1340 quartered with them, in the first quarter, the arms of France, azure, semée of fleurs-de-lys or. Thus they continued till the latter part of the reign of Henry IV., when the fleurs-de-lys were reduced to three. No alteration occurred in the royal achievement during any of the succeeding reigns till the accession of James VI. of Scotland to the throne of England, when that sovereign introduced the royal arms of Scotland into the second quarter, and the arms of Ireland into the third quarter. The royal arms were thus borne by all the monarchs of the house of Stewart till the reign of Anne, though William III. bore over the quarterings of the royal arms those of his Dutch dominions—the house of Nassau. In the

FIG. 1.—Arms of Great Britain.

reign of Anne a change again took place, occasioned by the union of England and Scotland; and the arms of these kingdoms were impaled in the first and fourth quarters (England on the dexter, Scotland on the sinister); France was removed to the second; and Ireland retained its former position. On the accession of the house of Brunswick in 1714, the fourth quarter in the royal shield gave place to the arms of his Majesty's German dominions, an arrangement which continued till 1st January 1801, when, upon the Union of Great Britain and Ireland, the arms of France were excluded, England occupied the first and fourth quarters, Scotland the second quarter, and Ireland its old position in the third quarter; while over all, on an escutcheon of pretence, were placed the arms of Hanover, ensigned with the electoral bonnet, in 1816 exchanged for the Hanoverian crown. On the death of William IV. Hanover passed away, and its arms were withdrawn, and the present arrangement introduced. In Scotland, and in

Scotch official documents, the Scottish coat is placed in the first quarter. It bears "on a lion rampant, within a double tressure flory-counterflory, gules." There is no positive authority for any early coat of arms being used for Ireland, though the bearing "azure, 3 crowns in pale or" granted by Richard III. to De Vere has been so regarded. From the reign of Henry VII., "azure, a harp or, stings argent," has been regarded as the Irish coat, and as such is inserted into the imperial shield. There is no authority of any standing for a coat of arms for the whole of the principality of Wales, but the coat usually attributed to it is "quarterly azure and gules, 4 lions passant guardant, counterchanged." The ancient princes of Wales would scarcely have adopted the lions of England. Moreover, this coat was never used by any leading chief in either middle or south Wales.

In Scotland arms territorial are much recognized. The dukes of Athole quarter Man. The gairis are quartered by the Erskines for the earldom of Bute. When Archibald Douglas was created duke of Touraine, he placed the arms of that duchy, three fleurs-de-lys, on his first quarter, before those of Douglas, Annandale, and Galloway. The dukes of Richmond bear three buckles for the dukedom of Argyre. "Faly of 6 argent and sable" are the reputed arms of the earldom of Athole, and "a saltire between 4 roses" those of that Lennox.

To this lead belong arms of pretension, when a sovereign claims *de jure* a possession which he no longer holds, and sometimes never held, *de facto*. Thus the kings of England from Edward III. to George III. bore the French lilies, and claimed to be kings of France, and the kings of Sardinia and Naples used the arms of Cyprus and Jerusalem. In fact, nearly all the older sovereigns of Europe used arms of this character. The armorial shield of the house of Austria at the dissolution of the empire afforded a number of curious examples of arms of pretension. Besides Hungary, Bohemia, Dalmatia, and Slavonia, it contained Aragon and Sicily, Brabant, Swabia, Antwerp, Flanders, Burgundy, Naples, Jerusalem, Lombardy, and Milan.

2. *Arms of Communities* are borne by corporations, religious houses, colleges, cities and boroughs, the cinque ports, guilds, and mans of court, some of which were allowed arms from an early period. These are very generally adopted in honour of some founder, great benefactor, or early and distinguished member of the body. Thus Birmingham bears the arms of the barons of the name, Manchester of the Byrons, Leicester of the Bellomonts, Cardiff of the De Clares. Of religious houses Atherton bore the arms of Basset; Garendon of the earls of Leicester; Kirby-Ballers of Ballers. Of colleges, Balliol and All Souls at Oxford, and Pembroke and Clare at Cambridge, so commemorate Balliol, Clitchele, Valence, and De Clare. The Cinque Ports all bear a part of the arms of England. The arms of the guilds and city companies usually contain some allusion to their trade; those of the grocers are 9 cloves; of the fishmongers, 3 dolphins; of the blacksmiths, 3 hammers. Of the mans of court, the Inner and Middle Temples bear badges of that order; Lincoln's Inn uses the purple lion of the De Laoy, earls of Lincoln; Furnival's Inn the bend and martlets of the Barons Furnival. A bishop, as a corporation sole, represents his see and bears its arms. These usually contain some ecclesiastical emblem, keys, crosses, mitres, martyrs' crowns, or the like. Hereford bears the arms of Cantilupe, possibly from its canonized bishop of that family. The arms of Lichfield and Coventry are founded upon those of Jerusalem; London, Winchester, and Bath and Wells assert their temporal power by bearing swords. The English sees were early provided with arms, but in Scotland they were of very late introduction. Bishops before the 17th century seem

to have used their personal arms Thus Gawain Douglas, bishop of Dunkeld,

"Who gave fair Scotland Virgil's page,"

and Alexander Douglas, bishop of Moiry in 1606, placed the Douglas arms upon their seals Sometimes, however, this seems to have been combined with some ecclesiastical emblem, for the archbishops of St Andrews placed the cross of St Andrew on their seals, while below were their personal arms, and the bishops of Glasgow so bore a figure of St Mungo.

3 *Arms of Office* are not uncommon The electors and chief officers of the empire each bore some token of their office The crossed swords so well known on Dresden china were borne by the electors of Saxony, the sceptre by those of Brandenburg, the crown of Charlemagne by the electors of Hanover as arch-treasurers The ancestors of the dukes of Osnabrück were hereditary butlers of Ireland, and bore three covered cups The kings of arms bear arms of office Garter, the principal king, bears "argent, a cross gules, on a chief azure a crown or encircled with a garter of the order buckled and nowed between a lion of England and a lion of France," by no means such an example of heraldry as might be expected from the chief herald of England The knights of St John of Jerusalem augmented their paternal arms with a chief gules, charged with a cross or Several civic offices in France gave a right to bear arms Ménéage observed of a mayor of Angers who died upon his election, and was buried with his newly acquired arms—

"Il étoit de bonne nature,
Et ne fut armé qu'en peinture."

4 *Arms of Concession* were granted by a sovereign or some feudal superior, sometimes in memory of some great deed, but more frequently to indicate the connexion between the lord and his follower, when they are called arms of patronage Of the former character was the heart in the arms of Douglas, first used by William I., earl of Douglas, 1355, in memory of James Lord Douglas's ransom with Robert Bruce's heart, and to this a crown was added in the time of William II., earl of Angus, in 1617 Also the families of De la Warr, Pelham, Vane, and Fane bear arms in allusion to the share of the ancestors of each in the capture of John of France at Poitiers Sir James Audley, after Poitiers, not only divided the Black Prince's present between his four squires, but allowed them to bear portions of his coat armory, "gules, a flet or," in memory of which the family of Delves still bear "argent, a chevron gules, fretty or, between 3 billets sable" (fig 62), and that of Darton, "quately argent and gules, on the 2d and 3d quarters a flet or." It was probably in memory of the same event that John Touchet, Lord Audley, granted to John and Thomas Mackworth, for services performed by their ancestors and themselves to his ancestors and himself, to bear "party dentelle de sable et d'hermines, un chevron de gules fretty d'or,"—arms still used by the Mackworths, with a slight addition, and now blazoned "per pale indented sable and ermine, on a chevron gules 5 crosses patée or." Among many similar instances may be mentioned Tatton of Cheshire, who bears "quately argent and gules," evidently derived from Massey Harvey of Ickworth bears "gules, on a bend argent 3 hawks slipped vert," derived from Foliot, who bore "gules, a bend argent." Stanton of Longbridge, who bore "argent, 2 chevrons within a border engrailed sable," derived from Albin of Belvoir, who bore "or, 3 chevrons and a border gules." Lowther and Musgrave derive their armulets from Vipont Moton of Peckleton, Baisford, Astley of Hillmorton, Besington, bore "argent, a cinquefoil azure," "or, a cinquefoil sable," "azure, a cinquefoil ermine," and "azure, a cinquefoil or,"

all derived from the bearings of the Bellomonts, "gules, a cinquefoil ermine." Hairdress, who held under De Clare at Tonbridge, bore "gules, a lion rampant debased by a chevron or," and the lords of Avan, Welsh barons under De Clare, bore the three chevrons Thus also Flammville and Whaiton used the mannik of Hastings "Ermine and chequy," from the Newburgh earls, were common in Warwickshire, and the "cantons" in Westmoreland, derived from the Lancasters, barons of Kendal In Donglesdale the "stars" of Douglas preponderate, and in Annandale the "sablure" of Johnstone.

Arms also passed from one friend to another by deed or will, even when there was no blood relationship Henry de Lucy, the last earl of Lincoln, bequeathed to his friend and executor Sir H. Scrope a lion passant guardant, in augmentation of his coat, and Sir Henry wore it accordingly, though for life only Maud Lucy, heiress of her brother Anthony Lord Lucy of Coddemouth, married Henry Percy, earl of Northumberland, 1414 She died childless, but bequeathed her lands to the Percys on condition they bore her arms, "gules 3 lions," quately with Percy, which they continued to do, and indeed, though without any right, often styled themselves Barons Lucy To this class also belong arms of augmentation, sometimes called additions of honour Thus Richard II. chose to impale with his only legitimate daughter, the Countess of Arundel, "gules, a cross patée between 5 martlets or," and he granted to Thomas Holland, duke of Surrey, to impale them with a border argent with his own arms Thomas Mowbray, duke of Norfolk, was also allowed to impale the entire arms of the Countess, a fatal gift, as it was one of the charges brought against his ambitious descendant Henry Howard Richard also allowed De Vere, duke of Ireland, to bear for life "azure, 3 golden crowns within a border," which seems then to have been regarded as the arms of Ireland They are found on the marshalled quarterly with De Vere After the victory of Flodden, Henry VIII. granted to the earl of Surrey to augment his arms with a "demi-lion gules passant through the month with an arrow, within a double trefoil flower of the same," to be placed on the Howard bond Henry used both the pile and the branch in his augmentations to the families of his English wives Seymour bore "quately, 1 and 4, or, on a pile gules between 6 fleurs-de-lys azure 3 lions of England, 2 and 3, Seymour." The augmentation to Catherine Howard includes 2 flames, that to Catherine Parr a pale Mannors of Bolton bore "or, 2 bars argent, a chief quately azure and gules, in the 1st and 4th quarters 2 fleurs-de-lys, in the 2d and 3d a lion of England, or." The bars were no doubt taken from the Muschamps The chief and its contents were an augmentation from Henry VIII.

In Scotland an early Lord Seton had a concession from Robert Bruce of a sword supporting a crown, and his descendant in 1601 received as an augmentation "azure, a blazing star of 8 points within a double trefoil or."

Most of the earlier grants or concessions seem intended to commemorate some territorial or genealogical concession, those of later date some connexion with royalty, or some deed of arms in the field Thus Sir Cloudesley Shovel received 2 fleurs-de-lys in chief and a crescent in base in memory of two victories over the French and one over the Turks, and Nelson and other naval commanders received additions rather to be described as sea pieces than as heraldic augmentations.

5 *Family and Paternal Arms* and arms of succession are such a descent by custom to the male heir. The descendants of females, however, have by special licence, can only quarter their arms This rule has indeed been much abused, and on every side are seen good maternal names and arms adopted to the exclusion of those less dis-

tinguished on the paternal side. Paternal arms are of very various dates and origin. There seem, however, always to have existed certain recognized rules which the earl marshal had power to enforce. One of the most important of these was that no two persons in the same kingdom should bear the same arms, a practice clearly subversive of the main use of such insignia. Many were the disputes and challenges that arose out of this regulation, of which two of the most remarkable have already been mentioned.

6. *Arms of Alliance* or *heirship* were used when those of a great heiress were allowed to supersede the paternal coat. Thus the heiress of Mandeville, earl of Essex, married Say, and their heiress, Beatrice de Say, married Geoffrey Fitz Piers. Geoffrey (died 14 John) became earl of Essex, and their descendants took the name and bore the arms of Mandeville exclusively. William II., earl Warren (died 1148), left a daughter and heiress Isabel, who married Hamelin, natural son of Geoffrey of Anjou and brother to Henry II. He became earl of Surrey, and bore the name and arms and continued the line of Warren. The De la Bisse family, who claimed to descend from the male stock of the De Clares, bore the 3 chevrons differenced with a label of 3 points, though when, in the reign of Richard II., they intermarried with the Staffords, they laid this aside, and adopted "a chevron between three roses." When Gilbert Talbot (died 1274) married Gwenllian, or Gwendoline, the heiress of the Welsh prince Rhys ap Griffith, he laid aside his paternal coat, "bendy of 10 pieces, argent and gules," and adopted that of the lady, "gules, a lion rampant or, within a border engrailed of the field," as still used by the earls of Shrewsbury.

7. *Arms of Attribution* are altogether fictitious, and such as the heralds of the 15th and 16th centuries indulged in to an absurd extent, providing every hero of antiquity with a coat of arms. The same age that represented the Virgin Mary as vested in the canon law declared that Solomon, as the wisest of men, must have been a good herald, and described the armorial bearings of Achilles and Hector. Perhaps the most extravagant example of this fashion is contained in the work of Dame Juliana Berners, who says: "Of the offspring of the gentleman Japhot, comes Habraham, Moyeses, Aron, and the profeteys, and also the kyng of the right line of Mary, of whom the gentillman Jhesus was borne, very God and man; after his manhood King of the londs of Jude and of Jude, gentillman by his modre Mary prynce of coat armure;" and again, "The four doctors of holy church, Seynt Jeromy, Ambrose, Augustyn, and Gregori, vray gentillmen of blode and of cotarmures." At an earlier period, in the reign of Richard II., it was believed that many of the bearings in use had been borne ever since the Conquest, as appears from the evidence in the Scrope and Grosvenor controversy. Almost all the older genealogists attribute coats of arms to ancestors long before they were in use. On the tomb of Queen Elizabeth are emblazoned the arms of William the Conqueror and Matilda of Flanders, and of Henry I. and Matilda of Scotland, all of course pure inventions. It is only of very late years, since a critical spirit has found its way even into heraldry, that these absurdities have been exposed.

8. *Canting Arms*, the "armes parlantes" of French heraldry, are common to all the preceding classes of arms, and most common in those of the earliest date. Such were the castle and lion for Castle and Leon, the fers de cheval of Ferrers, the lion (lwe) of Louvaine, the lucas of Lucy, the sharp-pointed row of fusils of Montacute, the carbeu or raven of Corbet, the herons of Heron, the falcon of Falconer, the greyhounds (levriers) of Manleverser, the hamolets of Bernak, the castle of Chastell, the swine's head of Swinbourne, the pentateuths of Compennie, the birondelles of Arundel, the storm-fishes of Tempest, the hammers of

Hamerton, the tyrwhits of Tyrwhitt, the hanks of cotton of Cotton, the fusils of Trefusis, the oren of Oxenden, the fer de moline of Molyneux, the hazel leaves of Hazlerigge, the Danish axes of Hakiuyt, the bozons or bird bolts of Bolteham and Bozon, the bend wavy of Wallop, or Well-hope, the whelk-shell of Shelley, and many more, mostly early coats, and borne by considerable persons and families. In fact the practice was introduced whenever the name admitted of it, and sometimes when the allusion is very far-fetched indeed, as in the boar pig "verres," the crest of De Vere, and the cock for Law, alluding to his cry, cock-a-leary-law! Canting arms were equally common in other countries. In Italy the Colonne, Frangipani, and Ursini families bore a column, a piece of broken bread, and a bear. They were also common in France, Spain, and Germany.

TINCTURES.

Tinctures (in French, *émaux*) include metals, colours, and furs. The Metals are—

Or	Yellow	Topaz	Sol.
Argent	White	Pearl	Luna.

The Colours—

Azure	Blue, azur	Sapphire	Jupiter.
Gules	Red, gules	Ruby	Mars.
Purple	Purple, pourpre	Amethyst	Mercury.
Sable	Black, sable	Diamond	Saturn.
Vert	Green, sinople	Emerald	Venus.

The Furs—

Ermine, Vair, Ermine or Counter-ermine.	Ermine, Pean, Vair-a-point, Counter-vair, Potent-counter-potent.
---	--

Gules is thought to come from the Persian *gul*, "a rose," but more probably from *gula*, "the throat." The other terms are French. To the older colours have been added "sanguine" and "tenné" or tawny, a compound of red and yellow. They are almost unknown in English heraldry, and are symbolized, the one by sardonx and dragon's tail, and the other by jacinth and dragon's head. The blazoning by precious stones and planets, and even by the virtues, was a foolish fancy of the heraldic writers of the 16th century, and applied to the arms of peers and princes. Gwillim condescends to use it.

A shield is rarely of one tincture only. In the roll of Caerlaverock, however, Sir Euerminus de la Brette "La baniere ent toute rougea."

The original bearing of the Gournays of Norfolk seems to have been sable. De Barge of Lorraine bore "azure." The Captal de Buch, who figures in Froissart as a Guyenne knight, bore "or," and Bogue, a Norman knight, bore "argent."

The furs (fig. 2) are all supposed to be formed of the skins of small animals fastened together. Ermine and vair were long the only furs acknowledged, and even now the rest are not common. Ermine (a) represents the skin of the animal of that name, and is white powdered with black spots.

In vair (b) the skins in shape resemble small escutcheons, the wings representing the forelegs and the point the tail. The fur is that of a sort of squirrel, bluish-grey on the back and white on the belly, and thence called "vairus." The skins are arranged alternately argent and azure; and if of other colours they must be specified. There are varieties of vairs, as vair-er-

FIG. 2.—FURS

There are varieties of vairs, as vair-er-

point, where the point of one escutcheon is placed opposite to the base of that below; counter-vair (*b*), where those of the same colour are placed base to base and point to point. At first the vair was drawn bell shaped (*c*).

In ermine (*c*) the field is sable and the spots white, in ermine (*d*) the field or and the spots sable; pean (*f*) is the reverse, having golden spots on a black field. Erminites resembles ermine, save that the two lateral hairs of each spot are red. This fur, however, is seldom if ever used in English heraldry. Guillim in blazoning a fur prefixed the word "purled."

Potent (*e*) is a variety of vair, and often blazoned as "vair-potent." There is also a form of it called "counter-potent" (*g*). Manchester, of the county of Stafford, bore "potent-counter-potent, argent and sable, a bend gules." The escutcheons or skins are T-shaped, and resemble a "potence," that is, a gallows or a crutch head. Ermine and vair are used almost to the exclusion of all other furs. Even ermine is very rare.

The dukes of Brittany, earls of Richmond, bore "ermine" (this was the coat of John de Montfort, duke of Brittany, whose widow married Henry IV.); Latin, "per pale argent and sable, a saltire engrailed ermine and ermine;" Beauchamp (old), "vair, a label gules;" Grevel of Drakelow, "vair, ermine and gules;" Calvert, "paly of 6 ermine and pean, a bend engrailed counterchanged."

Of the colours, gules, azure, and sable are by far the most common in early bearings. They contrasted strongly with each other and with the metals. To preserve this contrast, arose the very early and general rule not to place metal upon metal, and colour upon colour. Scott takes the license of a poet to break this rule in *Armistice*, whose falcon

"Scar'd sable on an azure field,"

and in *Ivanhoe*, where the black knight bears "a fetter lock and shackle bolt azure, on a field sable." He pleasantly defended himself by quoting the arms of the kingdom of Jerusalem, "argent, a cross potent between four crosses, all or," which thus violates this fundamental canon. The French call such coats "armés à engueris." There are a few other less illustrious but early instances.

Venour, warden of the Fleet, 1480, bore gules on a fess sable, five escallops or, 2, 2, 1.

Lycester of De Tablay: azure, a fess gules between three fleurs-de-lys or.

Sir Richard de Rokelo, temp. Edward II.: "d'azur, a six lionsels d'argent, a une fesse de gules."

When an object is given of its natural colour it is blazoned as "proper." Thus in the insignia of the order of St George and St Michael we have "the archangel encountering Satan, all proper;" though the German family of Teufel displays a teufel or devil gules. A very striking contrast of colour is produced by a process called "counterchanging," where a shield is divided between two colours, and a charge placed over the dividing line is also divided between the same colours transposed.

Chetwode of Chetwode: quarterly, argent and gules, four crosses patés counterchanged.

Peyto of Chesterton: Barry of six party per pale dancette, argent and gules counterchanged.

A very convenient practice of representing the tinctures by certain marks and lines arose in the 16th century, and is attributed to Padre Silvestro de Petro Sancto, an Italian. It was devised to allow of the representation of armorial bearings in drawings or engravings where it was inconvenient to colour them. Planché states the earliest known instance of the use of this method in England to be in an engraving of the seals of the regicides attached to the death warrant of Charles I. Sir E. Bysshe in Upton, 1664, gives a representation of these marks. Or (*fig. 8*) is represented by hatched points; silver is plain; azure is represented by horizontal lines, gules by vertical lines; those for purpure are drawn diagonally from sinister to dexter,

and those for vert from dexter to sinister. For sable, the lines are vertical and horizontal; for sanguine, diagonal,

FIG. 2.—Representation of Tinctures. a, ori; b, argenti; c, azuri; d, gules; e, purpure; f, sable; g, vert; h, sanguine; i, tanné.

or in saltire, from right to left and left to right, a compound of purple and vert; and for tanné, diagonal from sinister to dexter, and horizontal, a compound of purple and azure.

PARTS OF ARMS.

These are (1) the escutcheon; (2) the ordinaries; (3) partition lines; (4) charges.

The Escutcheon.

The *Escutcheon*, écu, or shield, called in blazon the field, upon which all lines are drawn and charges delineated, represents the shield borne in war upon which the arms of the knight were displayed. The figure of the shield varied in heraldry as in war. First came the long-pointed, kite-shaped shield or "pavane," slightly convex, and used with chain armour. As late as the reign of Richard I. and John

FIG. 4.

FIG. 5.—From the Bayeux tapestry.

such may be seen on early effigies, commonly but by no means always without armorial bearings, which were not then generally in use (*fig. 4*). Varieties of this are the heart-shaped or pear shaped shields (*fig. 5*), and sometimes a shield representing a third part of a cylinder with square top and bottom, much used in siege operations. Early in the 13th century was introduced the small heater-shaped shield, also triangular but narrow, short, and somewhat lance-shaped. This was in use in the reign of Henry III., and in the Early English period of architecture (*fig. 6*). The three water budgets of Ros appear on a shield of similar form of the date of Edward I. in the Temple Church (*fig. 7*). As coats

FIG. 6.

FIG. 7.

FIG. 8.

of arms were then simple, this shield was large enough to contain them without crowding, and therefore with sufficient distinctness. When drawn or carved in architecture it is suspended by its "gules" or shield straps, either upright or by the upper sinister angle, when it is said to be "conché." *Fig. 8* is from the great seal of Thomas de Beauchamp, earl of Warwick, and shows the form of shield in use during most of the Edwardian period.

As stuted and fancy plate armour came into fashion, the shield also altered its figure and became four-sided, and concave in the top and side edges, with a central point below; a notch also was cut in the upper dexter corner to

allow the lances to reach its rest, which projected from the breastplate, as in the shields upon the tower of the chapel of the Babingtons at Dethick, and on their tombhouse at Kingston (fig. 9). Such shields were called "chancree," or "à la bouche." They are frequently carved as an ornament in the Perpendicular style of architecture. As the shield ceased to be used in war, and was only known as a representation upon tombs or in pedigrees, it was altered to suit the fashionable practice of introducing large numbers of quartered coats, frequently twenty or thirty, and sometimes a hundred, as in an escutcheon of the earls of Huntingdon in Burnham church.

Fig. 9.

In the construction of the shield, while actually used in war, great strength had to be combined with as much lightness as possible, and this was attained by the use of cuirbouilli and plates of horn stretched upon a wooden frame. The cramps and cross pieces employed to stiffen the whole are sometimes seen upon early shields, and are supposed, with much reason, to have been painted or gilded as ornaments, and to have given rise to the bars or ordinaries which predominate in the first simple coats. Our acquaintance with the forms and fashions of the earlier shields is chiefly derived from their representations on tombs, but the actual shield of John of Gaunt was long preserved in old St Paul's, and that of the Black Prince still hangs above his tomb at Canterbury, as do those of his father and of Henry V. at Westminster. An unmarried woman did not place her arms upon an escutcheon, but, whether maiden or widow, upon a lozenge, an early practice in allusion probably to a fuil or distaff. When married she shared the shield of her husband.¹ The lozenge is an ancient usage, being found in the seals of English ladies of the middle of the 14th century, and in Scotland a century later. In modern heraldry the shields of knights of an order are usually oval or circular, called "cartouches" shields, and encircled with a ribbon bearing the motto of the order. When married the knight's arms are blazoned alone within the ribbon, and again represented with those of his wife in a second shield encircled with a plain ribbon, and placed on the sinister side of the other. The dexter side of the escutcheon is that on the proper right of the bearer and therefore on the left of the spectator.

To secure due precision in blazoning, nine points, indicated by as many names, are taken on the surface of the shield. These (represented by the letters in fig. 10) are—at the top in a horizontal line three, the middle, dexter, and sinister chief; at the base three, also horizontal, the middle, dexter, and sinister base; and in the central or vertical axis also three, of which the upper is the honour point, the lower the nornbril point, and the middle the fess point—the central point of the shield. The last three are of course in a line with the chief and base middle points.

Fig. 10.

Before passing to the ordinaries, it will be convenient here to mention a species of decoration applied to the shield, which, though not strictly heraldic, is often used in early heraldry and called "diaper." A shield "diapered," "bracteatus," is covered with a ground pattern usually in squares or lozenges with a flower or scroll work in each

compartment. The idea is said to be copied and named from the linen cloths of Ypres. An often-quoted example of diaper, and a very good one, is the shield of Robert de Vere upon his tomb at Earls Colne (fig. 4). Also the shield of William de Valence upon his effigy in Westminster Abbey is a very fine example of diaper. There the ground is divided into small squares, and each contains a pattern. The row of shields in the tabernacle work of the old chapel of St Stephen's, Westminster, exhibits some fine specimens of diapered work in squares, lozenges, and circles. The shield of Earl Warren at Castle Acre Priory is a good example of diaper, as is the counterseal of Thomas le Despenser affixed to a Kenig charter in 1397 (fig. 11).

FIG. 11.—Counterseal of Thomas le Despenser.

Ordinaries and Partition Lines.

The Ordinaries, or, as they are called in most heraldic books, "the honourable ordinaries," have been supposed to represent the clamps or fastenings of the shield, converted into ornaments by painting or gilding. They may be regarded as nine in number—the chief, the pale, the fess, the chevron, the bend, the cross, the saltire, the pile, and the quarter. When charged they are drawn somewhat broader than when blank, and each has one or more diminutives. All were more or less in use in the earliest times of heraldry, and they were then drawn more boldly and narrower than is now the custom. When such of the ordinaries as admit of it are cut short so as not to reach to the margin of the field, they are said to be humettée or coupée.

Partition Lines, closely allied to the ordinaries named from them, are the lines by which shields may be divided, and which vary both in direction and pattern. It will be convenient to notice these before proceeding to a detailed account of the ordinaries, as the partition lines will be constantly referred to in the examples. When the field is divided in the direction of an ordinary it is said to be "party per" that ordinary, as party per fess or per bend. Party per chief is rare, party per pile or per quarter unknown; party per cross is called quarterly; party per cross and per saltire is gyronny. When the partition line is mentioned without qualification, it is a straight line, but it may be broken in a variety of ways, as indented, dancette, engrailed, invected, undy, nebuli, embattled, dove-tailed, and raguly. These partition lines in some cases, if not in all, have arisen from the outline of a charge or bearing. Thus Charnels of Saresston at first bore eleven

¹ When an eminent geologist and proprietor of a well-known patent machine left his business for the militia, and after a short time returned to civil life, it was said:

"So maidens who to Hyppon yield
Exchange the lozenges for the shield,
But, when they lose the best of men,
Return to lozenges again."

lozenges conjoined in crosses, which at a later date became a cross engrailed, and finally in the same way became converted into dancette. In English heraldry the partition lines are per pale, per fess, per chevron, per bend dexter and sinister, quarterly, per saltire, and gyronny.

The annexed shield (fig. 12) represents these partition lines. It may be blazoned—quarterly of nine coats: 1. Butler: or, a chief indented azure; 2. Fleetwood: party per pale abably, azure and or, six martlets counter-changed; 3. Vavasseur: or, a fess dancette sable; 4. or, a chevron inverted azure; 5. Boyle: party per bend embattled, argent and gules; 6. Trever: party per bend sinister, ermine and ermine, a lion rampant or; 7. Lawrence: argent, a cross raguly gules; 8. Bodestoun: or, a saltire engrailed sable; 9. —party per fess dovetailed, or and sable. A good example of a cross raguly, not an armorial bearing, is found upon a 12th century tomb in the church of Llanllunogel-y-Gwynn in Pembrokeshire.

Fig. 12.

The French use *parti* and *coupé* for per pale and per fess; they do not *parti* per chevron, but per bend and per bend sinister are *tranché* and *taillé*; quarterly is *écartelé*, and per saltire *écartelé en sautoir*; gyronny is *gironé*. Besides these the French have a number of other divisions, as "tierce" when the shield is divided into three parts, as "tierce en pal, tierce en fesse, &c." Tierce en pal is convenient when the coats of two wives are to be marshalled on the husband's shield.

Formerly such broken lines as were used were not mere margins, but affected the whole ordinary; a fess indented was a zigzag and called a *dancette* or *dancette*. This practice is still preserved with the line undy. A bend undy or wavy is not a mere bend with a wavy edge, but the whole bend is in waves, whereas a bend nebuly or raguly has merely a particular kind of edge.

Returning to the ordinaries, it may be remarked that very many both of these and of the subordinaries in heraldry are very frequent constituents in mouldings in the Norman style of architecture. The chevron and the billet are amongst the most common. The roundel forms the hood moulding of a door at Peterborough, and is inserted in a moulding in the intersecting arches of St. Augustine's, Canterbury. The fret, the billet, and the roundel or palle are largely used in the oldest parts of Malmesbury, and on Lincoln tower is a good example of undy,—and this before the regular employment of heraldic bearings.

Fig. 13.

Fig. 14.

Fig. 15.

Fig. 16.

1. The *Chief*, chief, caput, is the upper part or head of the shield, covering one-third of it, and parted off by a horizontal line. It is found in the earliest examples of arms. In the roll of Henry III. it occurs fourteen times, in that of Edward II. twenty-one times. De Viroon: ermine, a chief gules (fig. 13). Butler (see fig. 12).

Arden: argent, a chief (fig. 14). St. John of Mochbourne: argent, a chief gules, two martlets played or (fig. 15). Cornwall of Tretwell: party per chief, gules and argent, a bend azure (fig. 16). might also be blazoned as gules, a chief argent, and a bend azure (fig. 16).

Heraldic writers give the *fillet* as a diminutive of the chief. It was a narrow strip laid upon the chief, a little above its lower margin. Guillim mentions, but gives no examples of it.

2. The *Pale*, pal, palme, is a vertical strip set upright in the

middle line of the shield, and one-third of its breadth. One of its earliest examples, if indeed it be not a mere gilt ornament, is ascribed to Grafsmannel, baron of Hinkley, who is reported to have borne gules, a pale; or, but the banner of the barons of Hinkley carried by Simon de Montfort was per pale indented, gules and or. The "sable pale of Mar" is the well-known bearing of Raskine, argent, a pale sable (fig. 17), but when it was introduced into Scotland is not clear. In the roll of Henry III. there occurs no pale, but there are three examples of pale. Party per pale is also there found. In the roll of Edward II. there is also no pale, but pale or party per pale occurs thirteen times. The latter is called simply "party"—Phyn, "party d'or et de gules."

Fig. 17.

Fig. 18.

Fig. 19.

Fig. 20.

The diminutives of the pale are the *pallet*, one-fourth, and the *endore*, one-eighth, of the breadth of the pale, both unknown anciently. The pallet may be used singly, the endore only in pairs, one on each side of the pale.

Marschal: parti Marschal and of Pembroke: party per pale or and vert, a lion rampant gules. Fleetwood (see fig. 12).

When the pale is repeated, it is blazoned as "paly," and the number of pieces specified.

Kingdom of Aragon: paly of ten argent and gules (fig. 19). Gurney: or, two pallets saur.

Phylis of Dunbar: argent, on a pale endorced sable three greyhounds' heads erased or, collared gules (fig. 19).

Phylis of Dunbar: argent, a pale finelly sable. Dalet of Cheshire: argent, a pale finelly sable.

Lighthof: azure, a pale rayonné or (fig. 20).

Fig. 21.

Fig. 22.

Fig. 23.

3. The *Fess*, fesse, fasces, is a strip placed horizontally across the middle of the shield. It occurs about twenty-five times in the roll of Henry III., and the diminutives about twenty-three times, or forty-eight times in all, against ninety in the roll of Edward II. Hagworth: gules, a fess argent (fig. 21).

Charlotte, queen of George III., on her shield of Mecklenburg-Strelitz placed a section of pretence party per fess, gules and or, for Sargard.

Yarrow (see fig. 12). Henry de Wroth, ancient blazer: azure, a fess engrailed or (fig. 22). This is a way of describing what is better known as azure, five fessules conjoined in fess or.

The seal of Walter son of Alan, steward of Scotland, 1160, gives a fess chequy, probably the earliest trace of the fess chequy.

Wald of Lulworth: azure, a fess rabilly between three crescents ermine (fig. 23). De la Planchette: argent, a fess embattled gules.

Permarston: argent, a fess embattled counter-embattled, between three esultes or. The Temple banner "Boissoneau" was party per fess sable and argent.

Riches in Cril: per fess or and gules. Swinburne (modern): party per fess gules and argent, three cinquefoils counter-changed.

Deanton: argent, a fess, quarterly, sable and or (fig. 24).

The diminutives of the fess are the *bar*, covering one-fifth of the field; the *barraule*, one-half, and the *cloze*, one-quarter of the bar. The cloze is used in pairs only, usually called *ganicles*, and these are sometimes quadrupled, two pairs on each side, and sometimes are used without the bend between them. The bar is rarely used singly, the number must be specified, if above four, when the coat or "barry" of the given number. The term *fassy* is not used.

Harcourt of Ankerwyke: gules, two bars or. Besset of Tekky: or, three bars wavy gules.

Elmest: barry nebuly of eight pieces, or and gules. Fitz Alan of Bedale: barry of six, argent and or.

Dehampton: argent, three bars hamely gules, barry in pale. Dehampton: argent, a fess gambled, gules (fig. 25). This is from the roll of Chatterbeck, but the more used blazon is—argent, a fess and two bars gambled gules, which might be given as a fess divided.

Peitrex of Denton: argent, three bars gambles gules, surmounted by a lion rampant sable or.

Huntrecombe: ermine, two pairs of gambles gules.

Edmondson and some other writers describe the gambles as *collets*.

4. The *Chevron*, chevron, cantelier, from whatever source derived, seems to have been named from its resemblance to the main rafters or principals of a roof, a familiar sight in early buildings. It is common to find orders on the royal forests for so many pairs of chevrons. Mr. Flanck points out that in the earliest English examples of this ordinary, in the seal of Gilbert, earl of Pembroke, in the reign of Stephen, the upper edge of the shield is pointed like a ridged roof, and the chevrons are parallel to it, and divide the

Carclebrook Latimer is described as bearing a cross patée, whereas the regular coat of the family was gules, a cross pattee or. Wm. de Fortuna, before 1241; gules, a cross pattee vair (fig. 48).

The cross fleury or fleurée is copied in a similar way by Beurs-dolys.

Lengthing of Lengthing: argent, a cross fretty sable (fig. 49).
Michael Savant or Sherd at Carclebrook bore sable, a cross fretty argent.

The cross moline is so called from the *for* de moline, or millrind, the iron clamp of the upper millstone. When the millrind itself is borne it is pierced, but the cross moline is not necessarily so. Its extremities are split, curved outwards, and end off square. It is an early bearing. When pierced this must be specified.

See of Evesley: gules, a cross moline argent.
Rogers of Selkirk: argent, a cross moline quarter-pierced or (fig. 50).

The cross potent, pattee, or eruchi or gibbet headed, has its extremities T-shaped.

An early example is seen in the arms of Jerusalem, argent, a cross potent between four crosslets or (fig. 51). Originally, however, the arms of the cross ended in knobs like the handle of a pilgrim's staff, thence called "bourdoine."

The cross rochevide has the ends split and curled outwards, but differs from the cross moline in having thorn pointed. The two bearings were occasionally confounded, and while the Baron Bess bore a cross moline, Bishop Antioch, his brother, is described as bearing a cross rochevide.

The cross voided is the outline only, called by the French "un croix faux;" the field is seen through it. The cross rochevide is usually also voided.

The lords of Grevenour bore "d'or, une croix void de gules, rochevide" (fig. 52).
Basing, temp. Edward III.: azure, a cross rochevide and voided or.

Fig. 50. Fig. 51. Fig. 52. Fig. 53.

The cross formée is peculiar among these varieties, inasmuch as its extremities reach the edge of the field. In other respects it resembles the cross patée.

Lewsey of Spensbury: argent, a cross formée chequy, or and sable.

Among the other, later, and but little used varieties of the cross may be mentioned the aveline, ending in filbert hanks; the cross anchored, of which the limbs terminate in anchors; the cross of the crucifixion or of Calvary, mounted on steps. A cross with a narrow border of another color is "fimbriated;" a cross pointed is where the ends are so cut.

7. The *Salvatore*, savior, or saviour, is known as the cross of St. Andrew, and is a common constituent in Scottish coats of arms. The origin is said to be a sort of stirrup or crossed loop suspended from the saddle by the stir of which the knight leaped into his seat. Such a stirrup certainly appears on the steed of Patrick, earl of March, on his seal, and on the seal of an early Despenner, and this is the only suggestion that accounts for the name. The *salvatore* is in breadth one-third of the field.

The Scottish emblem is azure, a *salvatore* argent; that of St. Patrick, argent, a *salvatore* gules. Now bore:

"A *salvatore* *salvatore* upon martial red,"

that is, gules, a *salvatore* argent (fig. 55).

Boisemont: or, a *salvatore* enfilé sable (fig. 56).

Gages: party per *salvatore*, argent and azure, a *salvatore* gules (fig. 57).

Charville of Gathfrinch: azure, three *salvatores* hemy or (fig. 58).

Brace: or, a *salvatore* and chief gules.

Fig. 54. Fig. 55. Fig. 56. Fig. 57.

Common charges placed upon a horizontal or vertical ordinary, as a fess or chief or cross, are placed upright; if on an inclined ordinary, as a bend or *salvatore*, their position should be specified; if upright, they are palewise; if inclined, bendwise or antipalewise. On the chevron they are upright unless otherwise specified.

Here the charges slope with the limbs of the *salvatore*, that in the center being upright. The deanery of Hingham, dedicated to St. Andrew, bore on its seal a *salvatore* raguly. The *salvatore* has no regular diminutives, but when several are borne they are conped.

8. The *Pile*, pile, is a triangular strip, its base one-third of the breadth of the shield, and usually applied to its upper margin, the point coinciding with the lower point of the shield. It has been

derived from the Roman *pilum*, a military weapon, and from the *pile* of the engineer. The origin is obscure, but it is a very early bearing. It has no diminutive.

Sir John Chandos, as Froissart often tells us, bore "d'argent, a saup ple de gules, a un label d'azuro" (fig. 57), and his ancestor Robert, temp. Henry III., bore or, on a pile gules three estoiles, between six of the same, counterchanged, an unusually complicated bearing for that age.

Waterhouse: or, a pile engrailed sable.

Frequently more piles than one were used, generally three, when they are to be blazoned as meeting in base.

Isabel de Armois: three piles saile meeting in base (fig. 58).
Thais: argent, three piles saile, one issuant from the chief between two from the base.

When the base of the pile is applied to any other part of the shield than the chief it must be specified. The pile was used by Henry VIII. as a vehicle for some of his grants of augmentation.

9. The *Quarter* or franc-quarter covers the upper dexter quarter of the shield. If placed in the sinister quarter, this must be specified. Its diminutive is the *crozier*, of two-thirds its area. Both are early bearings, but in the roll of Henry III. the quarter appears in several coats which in later rolls are blazoned with the cantons. Both are frequently charged. When either occurs in conjunction with another ordinary or subsidiary, they are placed above it, and therefore blazoned as is, as further from the field. Both are used as early differences, as in the families of Zouch and Bassett, and both are always borne with straight edges. A canton is also called a corner, and a cross between 2 crosses is said to be cantoned of them.

De Clare (old): or, a quarter gules (fig. 59).
Shelvey of Eastington: pale of six or and azure, a quarter ermine.

Barton of Strevord: argent, a canton sables; or a canton ermine Samuel Clark, the martyrologist: gules, a fleur-de-lis or, a canton ermine (fig. 60).

Fig. 58. Fig. 59. Fig. 60.

Subordinate Ordinaries.—These are the border, the inescutcheon, the orle, the treasure, the fret, the gyron, the fess, the lozenge, the fustil, the mascle, the minto, the roundel, gules or drops, the billet, and chequy.

The *border*, *bordure*, *fimbria*, or *limbus*, though a very old and independent bearing, was frequently used as a difference, and occasionally as a mark of illegitimacy. It is what its name expresses, and its breadth is one-fifth of the field. When used in an inquired coat the border is not continued round the inner side; in fact it is diminished. In old examples this was not always attended to. In a quartered coat the border is borne complete.

Sir Perdices d'Alnet, temp. Edward III.,
"Who only shield about his neck did fling,
Would he had done so better, never sinning,"
bore "gules, a border indenté argent."

Beault: ermine, a border argent, or sable saile (fig. 61).

Hamelin, illegitimate brother of Henry III., seems to have borne around his arms, on a border gules, eight *houlets* passant or. This was before quartering came into use. The augmentation granted by Henry VIII. to Courtenay, marquess of Exeter, was a *houlet* quarterly of England and France, the fleur-de-lis and *houlet* enmy, or in orle (fig. 62).

Fig. 61. Fig. 62. Fig. 63.

The *inescutcheon*, or *escusson*, is a small shield borne within and upon the greater one. It occurs in the earliest coats, and when voided becomes an orle.

Mentmore: Barry of 6 or and azure an inescutcheon argent, a chief of the first pale of the second between two gyrons of the same (fig. 63).

Albret of Albiac: argent, a chief azure, on a bend gules three inescutcheons party per chief, vert and argent (fig. 64).

The arms of Malahy, Lord of Kierro and earl of Nisbinnich, afford a good example of this subsidiary. They are, argent, an orle displayed sable, beaked and membered gules, surmounted with an inescutcheon of the first, charged with a *salvatore* of the second, surcharged with a *lozengy* of the first.

The *Orle* is the edge or hem, curl, of the inescutcheon, voided, and is therefore blazoned by the French as a *faux escutcheon*.

John de I. Chel "De goudes oec eenen fien oecochon d'argent, that is, "gules, in chief argent" (fig 65)
Winnerton of Stamford argent, an inescutcheon voided, within an esto of mail (sable) (fig 66)

The *Tremula* is in fact a native tree, almost always being double, and usually flowered. It is a favorite Scottish bairn, and is set with flowers de lys placed diagonally, the upper and the lower half on each side of the tremula, when it is blazoned "floy counter-floy." It is a native tree, and is found in the same early alliance between that country and France. The bearing is the only remnant within a double tremula, floy counter-floy, gules (fig. 67). The tremula was a common grant of augmentation from the crown for services of an military or of an ultimate. Scott of Thintine, had for arms France and bore on a bend arm, charged with a mullet, a floy counter-floy, and on a chief three floy counter-floy. The tremula floy counter-floy, the canting of the second.

"The threatened future of the claimant
to wealth by his child

The *Fied* was originally borne fectly, representing a fectle. The single fect is very rare in ancient times, but many of those families who at first bore fectly afterwards bore a fect. Fectly is usually composed of eight pieces.

Malthracia, sable, fectly or, which soon became and continued sable, a fect or (the fect)

When nailed at the joints it is said to be oloude

Tussel gules, a fiddle (fretty) clonelo on
Harrington sable, a flet argent, called also a Harrington knot (fig. 69)
Version of Sudbury argent, a flet sable

The *gnyon*, also an old being, is the lower half of a quarter divided diagonally. It is a Spanish ordinary, and said to come from "gnyon," a guest. It is seldom borne singly, and usually is gnyonny, when the shield is divided per pale, poi fess, per bend, &c., and per bend sinister into eight sections. If more, the number must be specified. In the earliest examples the divisions are twelve.

The *Flaque*, or flanch, is the segment of a circle taken out of the two sides or flanks of the shield, the margin of which forms the chief. They are always used in pairs, one on each side. This is a mark of great antiquity.

The *Vouge*, the diminutive of the flaque, has a flatter curve. The vouge in defensive armour was a guard piece either of plate or of mail, used to cover a void or unprotected space at the elbow or the wrist.

FIG. 71. gulls, two pairs' faces between as many flaps as (fig 71), alluded to in *Illustrations* by Mr. Hookham ILLU—

"Two leopard's faces were the arms he bore."

When the bearer was asked to give some verses descriptive of his arms to be placed at the head of a history of the family, his answer was—

"The branches, on our field of gales,
Denote, by known heraldic rules,
A race confined and obscure,
In mediocrity true.
By their position showing,
That their fathers' virtues living,
In their inherited wisdom dwindle,
By well judged purchases and matches,
In our ambition and ambition,
Such was the life our fathers led,
That homely life on, deep habited
In our whole moral composition,
Confining us to a like condition."

The lozenge, the masole, and the rustio are all derived from the licet or frutty, and do not appear originally to have been used singly.

The *Forence* is a square, set up diagonally like the diamond in playing cards. It is seldom used alone, and when the shield is covered with it, it is called *lozenge*.

Eltzwillium loryngy, argent and gule (fig 72)
Ho Burch: gules seven lozenges with ensigned 39

The *Masala*, or rather *masculy*, for originally it was so used, is said to represent a net.

De Quincy, earl of Winchester. "Guiles, all muscles d'el, voydes in clump,"
and afterwards, guile, even muscles, pronounced 9.9.1 (cf. 7.1).

The *Buxia* is of later introduction, and is not a common bearing It is a lozenge placed in its centre by a round hole
 Cusance or, a rustic table (fig 75)

The *Fusil* is an elongated lozenge, from the French fuson, a spindle, and is supposed to represent a distaff charged with yarn. A very early example of its use is

William of Wyndham and Wilson Patten family, crinine and sable, a canton or (8a. 7b)

Results of Analysis suggest a division between the spindles table

Fig. 75 Fig. 76 Fig. 77 Fig. 78

The *Roundel*, if of metal, is a simple disk, if of coal, it is convex, hilt & globe. It is seldom borne singly, and is named specially from its colour.

If Oi, a Beant " Argent, a late " Azur, a Hunt " Gnk, a le teau " Suble, a Pillot. Gunstone, oi Orices	If V est, a Pompey " Lenn, an Ongo " Sarguine, a Gufe " Pucpud, a Golpo
--	--

The last four are almost unknown in English lexicology. akin to these is the *fountain*, a dish, buried alive, argent and gules, to represent water. Although laurels, pines, harts, and tortoise were given in early rolls of arms, their names do not always carry their colors. They are blazoned as roundels d'or, pellets d'argent, tortoise de gules. The tortoise is sometimes called a senesc. The pellicot often stands for the roundel, and the bezant is called a talent, from a coin of that name current with the bezant in the East.

Alan In Touch Gules, bezants. This was after his reduced to ten bezants
4,3,2,1, with a quarter and sometimes center of Brittany, that is, "cannoe
(fig 77)

[illegible]

In early lists the annulet is blazoned as a false roundel, thus Vipont is said to bear gules, six false roundels on

Gules or drops are represented point shaped with a tail like a Rupert's drop, or the tears on funeral dirapiers. They are not found in the earliest coats. They, like roundels, are named from their colour, thus or—*gutté d'or*, *gules*—*gutté de sang*, argent—*gutté d'eau*, sable—*gutté de poix*, arme—*gutté de larmes*, vert—*gutté d'huile*.

Malory argent, a cross sable guite d'or
Winterbottom azur, guite d'au
Kington argent, guite de laime, on a chief azuris three barons' coronets, or
(fig 89)

City of Hartford argent, guile de sang, a cross of the same
 Chichester city argent, guile de poir, on a chief indented gules a lion of
 England
 Marchal argent on a fess gules three lions or

The *Billet* or dove is a small parallelogram usually being in numbers and set up on one end

Duke argent, a chevron gules, fretty or, between three doves sable (fig. 82)

Somewhat akin to these subordinaries is a division of the field known as *chequy*, where the field is divided into small squares like a chess-board. Their number is not specified, but usually is made up of seven squares in a line, and in depth according to the length of the shield. Hugh, earl of Vermandois, is said to have borne chequy, or and azure, and as his daughter married Warren, it is possible that the coats of Surrey thence derived their well-known coat.

Warren: chequy, or and azure (fig. 85).

Tutssel: chequy, or and gules, a chief ermine.

Fig. 82.

Fig. 83.

Fig. 84.

Chequy was not confined to the field, but was also applied to the charges upon it.

SHAW: or, a fess chequy, argent and azure.

Where there is but one row of squares, the bearing is called *gobony* or *compony*, if of two rows, *counter-compony*.

Gier: hary of six argent and azure, a bend compony of the first and gules (fig. 86).

THE ROY: gules, a border quarterly, ermine and counter-compony, or and azure.

Common Charges.

Next to the purely heraldic figures connected with the shield and their diminutives and subordinaries, come those imported into heraldry as charges from all quarters, including an immense variety of objects, natural and artificial, beasts, birds, fishes, reptiles and insects, flowers, and the fruits of the field, chimerae, astronomical and celestial figures, man and his parts, arms and armour, implements of war and the chase, ships, articles of dress, and a miscellaneous budget far too heavy to enumerate.

The rules for the placing of these charges are simple. If single, they stand in the centre of the shield; if two, in pale, or one over the other; if three, 2 and 1; if the number is longer the order must be specified (see fig. 85). The French carry the unexpressed understanding much further. With them, four pieces are placed 3 and 2; five pieces, in saltire; six are 3,2,1; seven are 3,3,1; eight are in orle; and nine are 3,3,3.

FIG. 85.—Different arrangements of charges upon a shield:—(1) 3 roses; (2) 3 roses in fess; (3) 3 roses; (4) 3 roses in bend; (5) 4 roses; (6) 6 roses in cross; (7) 6 roses in saltire; (8) 6 roses; (9) 6 roses; (10) 6 roses in orle; (11) 6 roses; (12) 9 roses; (13) 10 roses; (14) 10 roses; (15) 10 roses.

ANIMALS.

The following rules are applicable to the blazoning of animals. Generally, unless otherwise specified, they are shown in profile,

looking towards the dexter side; when to the sinister, the word counter is prefixed, "a lion counter-passant." Animals look to back are "addorsed"; face to face, "confronted"; facing the spectator, "guardant"; or "affronted"; looking away, "regardant"; when rising out of the edge of an ordinary, "assaut"; when out of the middle of it, "naissant." When the claws, horns, tongues, hoofs, or mane are shown of a special colour, the animal is "armed," "corneled," "lingued," or "languessed," "unguled," or "erined." Sometimes he is crowned royally or dually, sometimes "collared," "gorgeled," or "acollé." When wounded he is "vulned." When of its natural colour the animal is "proper," but if any be of any metal, colour, or fur, and divided by any partition lines, "When a head or member is torn off it is "erased." When cut off "couped." When men are clothed, they are "habited"; when nude, they are "atavages."

QUADRUPLES.—Of these the lion is by far the most popular, nor is his popularity confined to England. He appears not only in the British arms, but in those of Spain, Holland, Denmark, Bohemia, and Saxony, and many lesser states. Of Edward II.'s 618 unicorns, 225 bear lions in some form or other. The favourite attitude is rampant, but he may be passant, salient, stuant, sejant, couchant, or dormant. About thirty varieties of attitude are enumerated by writers; but most are rarely if ever used, and indeed it is seldom the lion is, other than rampant or passant. Sometimes he is borne "demi," especially as a crest. His paw or paws are also borne, and his tail.

In one or two well-known instances on the Continent he is "addorsed," that is, his head and neck and the tuft of his tail are cut off. When a member is borne upright, it is "erected." As a set off to this dismemberment, in early rolls the lion is sometimes represented as two-tailed, or "queue fourcée," and there are examples of bipeds and tricephals. In the arms of the Countess of Arundel above three lions are shown, they become lions or lions' whelps, unless otherwise specified.

It has been shown that as early as 1127 Henry I. used the lion as an ornament upon the shield he gave to his son-in-law, who bore those animals upon his brocade, as did the early French kings the fleur-de-lys. Mr. Planche has investigated this early use of the lion by Henry with great accuracy. A prophecy of Merlin, held to apply to that king, designated him as the Lion of Justice; his favourite residence and death-place was in the forest of Leon or Lyons in Normandy; his wife Adeliza was a daughter of Godfrey, duke of Louvain or Léven, a name which certainly gave rise to the lion as a mark of that family.

William, earl of Gloucester, Henry's grandson, sealed with a lion. Richard de Redvers, earl of Devon, who married a granddaughter of Henry, also bore a lion, as did Richard, earl of Chester, who married another grandchild. William d'Aubigny who married Henry's widow, used the same animal. All this occurred at a period when armorial bearings were by no means an established institution, and where every great noble was taking it up, and quite open to assume a bearing.

On the whole, therefore, it seems probable that to Henry I. was due the introduction of the lion into English heraldry. It has been seen that under Richard and John the lion became the actual arms of England, and this will account for the general adoption of the royal beast in English coats of arms. In humility a "lion passant guardant" is always blazoned as "a lion of England."

The identity of the lion of England with the leopard has been the subject of much controversy, and when Napoleon talked of driving the leopards into the sea he evidently used the word in disparagement of our national bearing. The early heralds, who probably were not zoologists, seemed to have confounded the lion with the leopard, and to have used the names according to the attitude of the animal.

When rampant he was a lion, when in any other attitude, as passant, he was leopard or a lion-leopard, but never drawn spotted like a real leopard. As the lion came more generally into use, and was borne in various attitudes, the allusion to the leopard was gradually dropped, though as late as the reign of Edward III. and Richard II. the royal coat was described as a leopard, and Henry V. had a Leopard herald. Among the greater barons of the 13th and 14th century, the lion was borne by the earls of Arundel, Cornwall, Devon, Hereford, Leicester, Lincoln, the Earl Marshal and the earl of Salisbury, as well as by scores of the lesser barons or knights. Sir Tristram, the knight of Isonce, bore a lion when

"Mountant with his majest,
With a lance in hand,
He smote him in the lion."

Fig. 86.

Fig. 87.

Fig. 88.

Fig. 89.

Lewis of Llanthorn and Cornwall their coat bore and bear, and a lion rampant argent a bearing still used by their cadets, the Lewises of Penryn-steads, who migrated above two centuries ago (fig. 89).

of the order of the Temple. A grey horse is a *harn*, a bay a *bayard*. When in the field he is free, when in harness harned and caparisoned.

Trevelyan of Northcombe, whose ancestor is supposed, in Cornwall, to have come out of the east at the Land's End ready mounted, inconspicuously enough, upon a land horse, bears gules, a demi land horse issuant from the water, all proper.

Horsey of Molecombe-Horsey: azure, three horses' heads couped, hatted, and chained or.

The *Ass*, probably the wild ass endowed with sublimity in the book of Job, found a place on the shield of the old Cheshire family of Hocklinton, argent, an ass's head issuant sable.

The *Ram*.—Recently a valuable silver dish was fished up from Whitloose Mere, having marks hatted at each end, evidently once the property of the Abbey.

Ramsey Abbey: "Ramsey the clerk," bore or, on a bend azure three rams' heads couped argent, armed at each end.

The *Sheep* is occasionally seen, but the *Lamb* from its religious association was in general use. The *Pascal Lamb* was one of the cognomines of the Templars, and is adopted with equal propriety by the gentlemen of the Jong role. As the "Lamb and Flag," is known extensively in South Wales. Price of Park and other descendants of Jestyn yn Gwrgan bore it as a crest.

Lambins of Lambton: sable, a fess between three lambs tripart argent.

The fleece of the sheep gave name to the great Burgundian order, and the toison d'or was its jewel. It probably refers to the personal wealth of Burgundy, and is said to have been founded by Philip the Good, in allusion, not to the bad faith of John, but to the prowess of Gildard.

The *Crest*.—William de Caynaville bore a goat "exallons." Thierbold of Barton: sable, three goats issuant argent.

The *Coney*. Coningsby of Hampton Court: gules, three conies argent.

The *Otter*.—Luttre was once as a supporter, by Luttrell of Dunster.

The *Squirrel*. Nuthall: argent, a squirrel rampant holding a nut, all proper, from a hatchment in Claybrook Church.

The *Hedgehog*, heron, abiding in the church of Gamston, Notts, is a fine effigy in chain mail of the end of the 18th century, of one of the family of Horle, and on the shield are three hedgehogs. They bore azure, three hedgehogs or. The hedgehog is also borne by the Maxwells for the lordship of Horle.

The *Mole*. Miers of Mifford: argent, a fess below three mole proper.

The *Prunelle*, the fur of which is worn by the Jews, is occasionally known in heraldry as an animal. The reader will, however, remember the three armures in the windows of Waverley House.

Bears.—The bird of heraldry before all others is the *Rapier*, the symbol of the fourth quarter. It is the lioness and chief popularity was in Germany, where it was adopted by the empire and by many of the principal sovereign princes.

It appears but twice in the roll of Henry III., but after his brother Richard, earl of Cornwall, became king of the Romans, he adopted the eagle, which on that account was to be seen in all the armorial glass of the midland shires, and was widely copied in private coats of arms. His son Edmund, while bearing "Cornwall" for his arms, suggested a shield from the back, and placed it on the breast of an eagle in reference to his father's rank. In the roll of Edward II. there are forty-three examples of eagles.

The nobles of the old Holy Roman empire place their shields upon the breast of an eagle, as may be seen in England in the flag of the duke of Marlborough as a prince, and of the earl of Denbigh and Lord Arundel of Wadour as counts, of that empire.

The imperial eagle is always represented with two heads, the origin of which is obscure. The emperor Frederick II. on his own temporary shield in Westminster Abbey has a single-headed eagle. The second head is supposed to have been produced by the diminution of two coats, such an eagle, but this is certainly probable. The eagle of the house of Brandenburg has but one head. Some of the North Wales gentry, headed by Sir Watkin Williams Wynn, place their shields upon the breast of an eagle, single-headed, and the practice is not unknown in Scotland. The seal of the widow of one of the Warwickshire Harpers in the time of Edward II. gives an eagle, and in his two claws shields of her husband's arms and her own.

Besides the eagle of Austria, Brandenburg, Russia, imperial France, and the United States, the bird was the emblem of Este, Bohemia, and Moravia, of many of the German, Italian, and French nobles, and of many very ancient English and Scottish names, as Montbatten, Redingfeld, Biddulph, Glyn, Weston, the England, and Ramsey, Maxwell, and Carnegie, in Scotland. The great financiers Rothschild use an eagle for their arms.

The eagle is always "displayed," that is, upright, with his breast to the front, and his legs tall, and wings expanded,—what is commonly known as a spread eagle.

When the beaks and talons of birds of prey are specified, they are said to be beaked and armed. In the roll of Henry III., Sir

Dru de Barenton bears sable, three eagles or, and his descendants in the reign of Edward II. had increased the number to six and gave them argent. Piers Gaveston bore six eagles upon his shield and his arms furnished.

Peter, earl of Richmond and Savoy, who built the Savoy Palace in 1250, and was uncle of Eleanor, countess of Henry III., on the shield of his monumental effigy at Aqua Bella bears an eagle for Savoy. The cross, the latter arms of that house, appear on the pennant of his sword. Long before this, about 1142, when Bluetien de Montmorenci married Alice of Savoy, he added four alerions or eaglets to his arms, probably in compliment to his wife, who bore an eagle displayed; and certainly in 1206 the acknowledged arms of the house of Savoy were an eagle.

Parts of birds, especially of eagles, are borne, as the head, wings, legs, and feathers. When feathers are used, and the quill is of a special colour, they are said to be grained. When a bird is leaving the ground it is "rising," when on the wing it is "au vol," when the wings are down it is "closed," when open "displayed."

Bedingfeld of Oxshay: ermine, an eagle displayed hary argent and gules (fig. 104).

Glynne of Tawdram: argent, a two-headed eagle sable (fig. 105).

Coleth of Coleth: argent, an eagle displayed, volant on a child in a mantle gules, beaked or. This is the crest of Stanley, well known in Lancashire as the bird and bearing.

Amory of Llantrithyd: azure, a chevron between three eagles' heads ermine or. Seymour: gules, two eagles wings conjoined in lure or (fig. 106).

Boys of Brier: argent, a chevron between three eagles' feet gules (fig. 107).

Fig. 104.

Fig. 105.

Fig. 106.

Fig. 107.

The *Falcon*, as an accessory to field sports, was much esteemed, and is often borne in heraldry. It is also called a *gerfauc*, *perge*, *falcon*, and *torcelot*. The falcon is usually borne with the jesses or leather thongs about its legs, sometimes with a hood and bells. It is then jessed, hooded, and belled. When feeding it is "at prey." The lure was a bunch of feathers towards which the bird was taught to return. On the seal of Alice, countess of Eu (1284-89), she appears on her husband's arms with the jesses du vert. It was the custom to slip over the claws of the young birds a silver ring, which could not afterwards be removed. Two such rings were found at Castle Hedingham, the seat of the De Vere, engraved "Or—on—la." One of gold found at Biggleswade bears "Sum regis Anglie," and within the ring "et comitis Herefordie." However well trained, these birds were always liable to prove rillers, that is, not to return to the lure—

"For though thou night and day take of him rede,
And strew his cage lure and soft as silk,
And give him sugar, honey, bread, and milk,
Yet right sure as that his dower is up,
So with his feet will spurn down his cup,
And to the wood he will, and wrenner." 82.

Falconer of Halkerton bore originally gules, three hawks' lures or. After a marriage with Douglas they bore or, a falcon's head proper, issuant out of a man's heart gules between three stars azure. The English Falconers bore argent, three falcons gules, jessed, belled, and hooded or (fig. 108).

Fig. 108.

Fig. 109.

Fig. 110.

Deger: or, on a bend azure, three falcons rising argent, beaked and belled of the field.

Bator: argent, on a fess gules three falcons' heads ermine of the field.

Ridder of Blyden: gules, a chevron between three hawk's heads argent.

Alderston: sable, three hawks' lures pointed, stringed, and ringed argent.

The Swan was the cognizance of the Boltons. Thunhyrth, earl of Hereford in 119, bequeathed to his son an arm lit argent with poulx de cygne blanche. "When poulx with a dunl court having a gold chain attached to it, it is called a cygne royal. The swan was marked or ticked according to the rank of its owner. By a statute of 22 Edward IV. no man having less than five marcs

"Herald's office after the blazoning of this coat. The old terms, gules, a pair of wings, and argent, were thought scarcely clear. York described it as gules, two wings conjoined in fess or. Ralph in fess or, a hawk's head with wings. Gene gave a pair of wings inverted and conjoined. Who shall decide amidst so many wars of the herald?"

put unum could lawfully keep a "game" of swans. The keeper who looked after them was the "grumet."

Primal of Deceit—swan, a hand engined between two cygnets royal crest. *swan, a chevron in between three swans, hand charged proper.*

The **Primal**, prou, is more common as a crest than the shield. He is usually represented with his tail spread, and is then blazoned as a "peacock in his pride," is seen in the crest of Mannes.

Purvis—argent, three peacocks in their proud proper.

Yeo of Devon—argent, a chevron sable between three *Twink Cobbs*, this expanded, proper.

The **Plum** is the most common as a crest than arms. When in plum he is usually valuing himself, and when full fledged on his nest he is blazoned as a "peacock in his pride."

Crest of New—gules, a pelican in her piety, or, the 139.

Pelican—argent, three pelicans valuing themselves proper.

The **Ostrich** is the better known as a crest as borne by Digby, as it is supported by the curls of Buchanan. The plum of ostrich feathers, the well known emblem of the Black Prince, gave rise to the arms of his maternal son, Sir Roger Clarendon, who bore on a bend sable, three ostrich feathers argent, passing through as many scrolls of the field.

Devises of Devon—argent, six ostriches, feathers, 8, 2, 1, white.

The **Stork**—blunt is of bluntye. argent a hand borne on a scroll sable.

The **Heard** is one of the few birds found in crests of arms. Crests of Chippas and of deacons in the roll of Henry III. One of the families was the bluntye of the field.

Wings of light—*"Fame"*

at the crest of James IV. they bore gules, three herons argent.

The **Comet**, comet, or comet, appears with a double pen in the arms of Larnell, argent, a hawk sable, billed and legged gules, holding in his bill a bunch of lavae vert.

The **Sheldrake**, a hawk, or hawk, was introduced into heraldry to suit Sheldrake, mayor of London in 1678, who bore a hawk, a hawk between three birds argent.

The **Deer**, a stag, is seen on the bearing of Corbet from the beginning of medieval times.

Crest of Merton—argent, a stag, sable.

Deer—argent, three stags, argent, on each a stag sable.

The **Deer** is a creature, bearing, and sometimes conjointly with the stag, known in the rock in the field.

The **Deer**, a stag, is seen on the bearing of Corbet from the beginning of medieval times.

Crest of Merton—argent, a stag, sable.

Deer—argent, three stags, argent, on each a stag sable.

The **Deer**, a stag, is seen on the bearing of Corbet from the beginning of medieval times.

Crest of Merton—argent, a stag, sable.

Deer—argent, three stags, argent, on each a stag sable.

The **Deer**, a stag, is seen on the bearing of Corbet from the beginning of medieval times.

Crest of Merton—argent, a stag, sable.

Deer—argent, three stags, argent, on each a stag sable.

The **Deer**, a stag, is seen on the bearing of Corbet from the beginning of medieval times.

Crest of Merton—argent, a stag, sable.

Deer—argent, three stags, argent, on each a stag sable.

The **Deer**, a stag, is seen on the bearing of Corbet from the beginning of medieval times.

Crest of Merton—argent, a stag, sable.

Deer—argent, three stags, argent, on each a stag sable.

though this is not always expressed, when but they are "em-bowed" is the dolphin in the crest of Countess.

The **Pike**, or line, is the oldest example of a fish in heraldry. Lady of Gloucester, Shakespeare's "James" (William) gules, a mace of cross.

The **Dolphin**, which on his zoological position may be, is heraldically a fish, as is also the **Walrus**. As the emblem of Dupont, the dolphin was adopted with the name by the arms of Dupont of the old French monarchy, who quartered with the family of the Duke of Lorraine.

Duke of Lorraine—gules, a dolphin passant argent, a dolphin passant argent, a dolphin passant argent.

Duke of Lorraine—gules, a dolphin passant argent, a dolphin passant argent, a dolphin passant argent.

Duke of Lorraine—gules, a dolphin passant argent, a dolphin passant argent, a dolphin passant argent.

The dragon was a favourite standard with the Welsh princes, and used also by the Anglo-Norman sovereigns. He is drawn with four legs and wings, a long barbed tail usually knotted, and a body protected by scales. In English heraldry he is used chiefly as a crest. In Wales, Rhys ap Iudor Mawr is said to have borne "argent, a dragon passant sable."

The *Gryphon* is popular both in romance and heraldry. He is an emblem of vigilance, and inhabited a mountain in Bæstria and guarded much gold there. It was in defence of this that he

"through the wilderness
Pursued the Arminian."

He is drawn with the body and tail of a lion, the head of a cock, a pair of wings, and very long sharp claws. When on his hind legs he is rampant.

Moose of Trelogar: or, a gryphon argent sable (fig. 112).
Eryon of Wotton: azure, a gryphon passant and a chief or.
Cotton of Landwade: sable, a chevron between three gryphons' heads erased argent.

The gryphon was an early cognizance of Rodvers, earl of Devon, and was used stoutly by some branches of the Montagues in the time of Henry III.

The *Wynnan* is a two-legged dragon with the body passing off into a long tail barbed at the end and usually borne bowed or knotted.
Drake: argent, a wyvern statant, tail depressed and noyed, gules (fig. 115).

Cockatrice.

Langley: argent, a cockatrice sable, combed gules.

The *Onyx* or *Hoerne* abounds in Scottish heraldry, and was made the sinister supporter of the arms of Great Britain by James I.

"Ceste merveilleuse beste,
Qui une corne a en la teste
Beneit nostre seigneur.
Icelle Onyx seigneur.
C'est l'hoerne escuier.
Qui entre le vierge prist cestel."

Hasting: argent, a unicorn argent sable, armed and unguled or.

The *Morcad*.

Ellis: argent, a mermaid gules, erised or, in her right hand a comb, in her left a mirror, argent.

The *Marbled*, or *marclotte*, a small bird without legs, and always represented close to the eye of the chief and commencing a charge of armor, but seldom if ever borne singly (see Fleawood, fig. 12).

Furnival of Parnham Bayle: argent, a bent between six marbled gules.
Roger de Mortier, roll of Henry III.: barry of ten, argent and gules, on a border azure eight marbled gules.

FLOWERS AND FRUIT OF THE EARTH.—Of these the palm was an emblem of victory; the laurel, of triumph; the oak, of strength; the olive, of peace; the cyprus, of war; the vine, of fecundity and joy; the lily, of purity; the daisy, of humility; while the holy

"Trefail, St John's work, and gill
Hinder wickets of their will."

Fleur-de-lis.—At the head of heraldic flowers, if flower indeed it be, is the *fleur-de-lis* (fig. 60), the *Flos gladioli* of Upton, said to have been brought down by the arms of France, and was certainly used by Louis VII. and borne singly and in numbers by Philip Augustus. It may be alluded to the lily—

"The lily, lady of the ducery field,
Or four-de-lis, the lovely pansourer."

or its original designation may have been "Fleur de Louis." It was not at first popular in Germany, or in England, occurring but twice in the roll of Henry III., and only twenty times in that of Edward I., nor was it until its assumption by Edward III. that it came into general use in England. The Cantilanes bore three fleur-de-lis before they added the pearls' head (fig. 98).

Dierly of Colchester: azure, a fleur-de-lis argent.
Portman of Orchard-Portman: or, a fleur-de-lis azure.
Beaumont: to show his claim to descent from the blood-royal of France, bears azure, a cinque of fleur-de-lis, a lion rampant or.
Hawkins: argent, an azalee sable, three lilies slipped argent.
New College, Oxford: sable, three lilies slipped argent.

The *Rose* (*Flos florum*) is a very popular charge in English heraldry, though in the roll of Henry III. it occurs but once, and in that of Edward III. only twice. Usually the flower is borne alone and full-faced, with five petals, and berries and seeds between them. If a stalk is shown, it is usually, "slipped," that is, cut off obliquely.

Beaumont of Beaumont-Rose: ormine, a rose gules, barbed and seeded proper (fig. 114).
Ellen, lady of Wyke-Rose: sable, a rose and pomegranate impaled dimittated, gules and or, barbed, seeded, stalked, and slipped counterchanged.

The rose is also used in the chaplet, a favorite head ornament, of which a good example may be seen upon the conical helmet of Humphrey de Bohemia, 1st, in Gloucester cathedral. After the gallant defence of Calais in 1559, in which Edward and the Black Prince served under Sir Walter Manny, the king was so pleased with the valor shown by his prisoner Eustace de Ribourcourt that he took a chaplet from his breast and gave it to Sir Eustace with the liberty, bidding him "be for a year for the love of me."

Greyhound: barry of six, argent and azure, three chequets gules.

The *Trefail*, *Quarterfoil*, *Cinqufoil*, and *Sixfoil* are all common charges, usually but not always borne, like the rose, without a stalk.

Harvey of Tewkesbury: gules, on a bend argent three trefails slipped vert.
Viviot of Stoke Watherton: azure, three cinquefoils argent (fig. 116).
Robert de Ballmoat, earl of Leicester (1191-1220), sealed with a cinquefoil, bearing on an enamel spot; and Robert de Quincy, the son of one of Earl Robert's sisters, bore "de gules une quintefoil de hermyen."

Unfearful of Denmark: gules, a sixfoil or.

Fig. 116.

Fig. 117.

Fig. 118.

The *Thistle*, which gives name to the Scottish order, is also an heraldic bearing in that country.

Leaves, sometimes, are borne by Leveson and Fenlis; hazel leaves by Hazleridge of Noceley; stammbury leaves, or falcia, by Fraser of Lovat; walnut leaves by Waller; oak leaves by Oakes; by Elmes of Lifford, elm leaves; rye and barley or grain by Ijye and Grindridge.

Highland bears three ears of bigg.
Wood and Borough bear trees rooted up or eradicated.
Borough of Chelwyth: gules, the stem and trunk of a tree eradicated and couped, spreading in two branches argent.

When Queen Elizabeth visited Worcester the citizens transplanted a pear tree laden with fruit into the market-place, for which attention she added pears to the city arms. Warden abbey, Beds, was famous for a pear that bore his name and constituted the arms—azure, three Warden pears or. The kingdom of Granada bore argent, a pomegranate slipped proper. Sir Jeanne bore argent, a saltire sable between twelve cherries slipped gules.

The *Garb*, garbe, or wheat-sheaf, was a common bearing, especially in Cheshire. Sometimes the garb is, banded of a different colour.

Grosvener: azure, a garb or.
Venice of Shipwright: or, on a fess three garbs of the field.

CELESTIAL FIGURES.—"The Sun was the cognizance of Louis XIV., with the overbearing motto, "Nec pluribus impar." In heraldry this was blazoned as "the sun in his splendor."

John de la Hay bore argent, the sun in his splendor gules.
Bapt de la Hay temp. Henry II., diffused this coat by bearing only a ray of the sun, "blanc, une ray de soleil de gules."
Sir John de la Hay temp. Edward I., bore a ray of the sun or. In both examples the ray issues from the dexter chief, and is borne handwise. It is usually a pale ray.

John de Fontibus, bishop of Ely, 1290-1304, bore the sun, moon, and seven stars, &c.

The *Moon* is always borne as a crescent, and usually with the concavity upwards. If this be to the dexter it is increasing, if to the sinister, decreasing. It is an early and general charge, though seldom borne singly.

Chapman: per chevron argent and gules, a crescent counterchanged.
Ward: azure, a rose nebula between three crescents ermine.
Baron of de Lincoln: argent, an eliot three moons increasing and decreasing argent in base an escutcheon or.
The seal of Sir Lawrence de Birkbeck, 1292, bears a chevron between three crescents (fig. 118).

The *Star*, or *estelle*, is usually shown with six rays, wavy, and is thus, and by not being pierced, distinguished from the mullet. If there be more rays the number must be given.

Ingilly of Ripley: sable, an azur argent.

One of the branches of De la Hay bore argent, an escutcheon of sixteen rays gules.
Sir Francis Drake, in memory of his voyages, bore twelve stars argent, between the ermine chief and ermine pale ten argent.

MAN AND HIS PARTS.—The full human figure is very rarely borne in coats of arms. In Scotland the DeMills bear sable, a naked man with arms extended, proper; formerly he was borne surrounded by a gilet.

Wood: azure, three salvages men annihilated in fess, proper; in their dexter hands a shield argent charged with a cross gules, in their sinister a club resting on their sinister, also proper.

Mr. Wye mentions an MS. at Malton, in which two knights are represented tilting before a French princess, one of whom looms for a coat three damoiselles argent in a basket.
Garnier of Foxcote: argent, three blackmoors' heads couped sable, capped or, fretty gules.

Fig. 119.

score and proclaimed it, with a valuable ruby, as a prize to be contended for. He saved himself with it, and the lady wore it for his sake. Fig. 123 is from the seal of John de Hastings, 1201.

The *Butterfly-arms* is borne by the Berties, earls of Lindsey, sometimes dukes of Ancaster, with the allusive motto, "Virtus alicui fortior" (fig. 122).

The *Encarnelle-arms* was a very early bearing of the Manlevilles. It is a cross of eight rays, set with knobs and the arms ending in fleur-de-lys. In another form the ends are constructed by cross-bars. The encarnelle of the reign of Henry III. resembles the iron work on doors of that period.

Mount of blazon: argent, two bars azure, over all an encarnelle of eight rays gules, fretty and pommelée or.

Among musical instruments the *Clavirin* is borne by Granville, and is seen on tiles at South abbey. It resembles a pan-pipe. The *Trumpet* is seen on the fine Trumpington brass near Cambridge.

Williams of Thame: azure, two organ pipes saltirewise, the dexter over the sinister, each with a sinister organ.

The *Water Dugget* or bucket is an early charge identified with the names of Ros and Rose. Rose, however, got it from the Trustees of Belvoir, who possibly bore it as lords of Watre in Holderness. Mr Planché has discovered a drawing of a pail of water duggets in actual use. They were of leather, and carried in pails on a stick over the shoulder.

Fig. 123.

DEBASED HERALDRY.

Of debased heraldry there is no lack of examples, and a few are ancient. Thomas de Insula, bishop of Ely (1345-81), bore gules, three bezants, on each a crowned king, robed sable, doubled ermine, sustaining a covered cup in his right hand and a sword in his left, both or. No doubt, like the arms of the counts of Chichester and Salisbury, this extraordinary coat was meant to be painted on a banner. Camden granted a great number of coats, mostly of a complex character, and since his time heraldic taste has not improved. Tetlow (granted 1760) bore "on a book erect gules, clasped and leaved or, a silver penny argent, thereon written the Lord's Prayer; at the top of the book a dove proper, in his beak a crowquill pen sable." Other grants show negroes working in a plantation, Chinese porters carrying cinnamon, &c. The grants to Lord Nelson and his gallant captains, and to the elder Herchel, are utterly unheraldic. It can scarcely be wondered at that Lord Chesterfield, correcting the Garter of his day, remarked, "You foolish man, you don't understand your own foolish business."

DIFFERENCES AND MARKS OF CADENCY.

The object of an armorial bearing having been to distinguish one iron-sheathed warrior from another, it was necessary to provide bearings for the members of a family, all entitled to take the paternal coat. This was managed by the introduction of a difference (French, *brisure*), usually some slight but well-marked alteration, sometimes by inverting the tinctures, sometimes by changing an ordinary or a smaller charge, as a bond for a fess, or a crosslet for a martlet. Where an heiress had been married a part of her coat was often introduced. The object was with a sufficient difference to show the connexion with the head of the house. The following examples are from the families of Hastings and Zouch. Females, who wore no armour, did not need distinguishing marks, and bore the coat unbroken.

Sir John Hastings bore (see fig. 123) or, a martlet gules, called "le phien armée."

Sir William Hastings bore the same, with a label of Pembroke.

Sir John Hastings bore the same, with a border of Valence.

Sir Edmund Hastings bore the same, with a label vert.

Sir Nicholas Hastings bore the same, with a label azure.

Sir Miles Hastings bore or, a fess and a chief, three mullets gules.

Sir Philip Hastings bore the same, with a label azure.

Sir Robert Hastings bore ermine on a chief azure, three mullets or. The label of Pembroke and border of Valence show the match with the heiress of Valence, earl of Pembroke. Sir Miles formed a distinct branch, that of Daylesford, probably before armorial bearings were fixed; his descendants, however, returned to the main line.

Sir Alan la Zouch bore gules, bezanty.

Sir William la Zouch bore the same, with a quarter ermine.

Sir William la Zouch bore the same, with a label azure.

Sir Oliver la Zouch bore the same, with a chevron ermine.

Sir Amory la Zouch bore the same, with a bend argent.

Sir Thomas la Zouch bore the same, on a quarter argent a mullet sable.

The quarter ermine is to show the descent from the dukes of Brittany.

These and many others of an early date are suitable for their purpose; but, as armorial bearings became less actually useful, alterations of a different character crept in. The label, however, retained its place. It closely resembles the strap with pendants which from the saddle crossed the horse's chest. The earliest example of its use is said to be by Geoffrey, son of Henry I., in 1153, but a more certain case is the seal of Saher du Quincy, though whether there borne as a charge or as a difference is uncertain. At Charlrook Maurice de Berkeley bore a blue label "parqueque ses parents." In Scotland William Fraser, in 1295, used a label of three points and on each three roses or mullets, probably meant for "fraises" or strawberry leaves. The mullet, crescent, and fleur-de-lys are used as differences about the same time. The label, even then, was most frequently used by the eldest son, but occasionally he used the crescent, and the label was taken by the second son. The royal house generally used the label, but occasionally the border. Edward I., as prince, bore a label of five points azure; Edmund Crouchback his brother, who married a French princess, charged the label with fleur-de-lys. His second son, Henry, bore England with a bendlet ermine. Thomas and Edward, second and third sons of Edward I., used labels. Edward IV., as prince, bore on his great seal a label of three, and on his countersal one of five points. John of Eltham, his brother, bore England with a border of France. The Black Prince, who bore France and England quarterly, added a label argent, and Richard, during his father's life, placed a cross of St George on the middle point. Lionel, third son of Edward III., having married the heiress of De Clare and De Burgh, used a label and on each point a canton gules, said to be the original arms of De Clare, and on his seal as earl of Ulster each point bore a cross for De Burgh. The number of points was matter of indifference, though usually confined to three. The label itself was, on the whole, and has continued to be, a mark for all the princes of the royal house.

Setting aside the royal family, a new system of differences came into use, and is touched upon by Upton early in the 15th century, though then but imperfect. It gives the crescent to the eldest son, and to the others the label with three or more points in succession. Dame Berners, in 1486, besides employing the billet, crosslet, and other marks, describes a method of differing by "gorrating," that is, powdering the field with billets or other charges, but the good lady's caps are often mere fancies. The first regular appearance of the modern system is on the offices of seven Beauchamp cadets in St Mary's windows at Warwick. There the label, annulet, crescent, martlet, fleur-de-lys, and mullet indicate the several cadets. The label is placed in chief, the rest on the fess point of each surcoat.

The modern marks now regularly admitted are—(1) the label of three points; (2) the crescent; (3) the mullet; (4) the martlet; (5) the annulet; (6) the fleur-de-lys; (7) the

rose, (8) the cross maline, (9) the octofol (fig 134). The eldest son of the eldest son places a label upon a label, the second a crescent, and so on, so that the ninth son of a ninth son would bear an octofol upon an octofol, pointing out the relationship of each member to the parent stock. Practically, however, marks of cadency are but seldom

FIG. 121—Mail's of Cadency

used. The emils of Hamington indeed, descending from the second son of a second son, place a crescent upon a crescent. Lords Abingvouny and Baybrooke difference their Noville saltire with a rose, as springing from the seventh son of Ralph, earl of Westmoreland. On the other hand Lord Derby, though a cadet, bears his arms unbroken. *Arms of Abernethy* are very various, and on the culver conis not to be distinguished from differences. Probably the earliest English example is afforded by Wm Long-poe, natural son of Henry II, who bore six hookeys, no doubt derived from his father, though usually attributed to his wife Ela, heiress of the earldom of Salisbury. His coat of arms bears the long sword whence he derived his name. The sons of Richard, brother of Henry III, bore their father's lion of Poitou, inverting the colour, until Sn Godfrey Cornwall took prisoner the duke of Brittany, when he changed his field to azure. In the roll of Edward II, Sn John Lovel le Bastard bore Argent, usually or gules, with "un label d'azur." Sn Roger Clarendon, son of the Black Prince, has already been mentioned (page 701). John Beaufort, son of John of Gaunt, bore per pale argent and azur on a bend gules three lions of England, with his father's label. After his semi-legitimization he bore England with a border gobony argent and azur, the Lancaster colour. Arthuri, Viscount Lisle, son of Edward IV, placed a baton over his father's arms. Sometimes the father's coat was altered. Sn John Stanley bore a coat compounded of Stanley and Lathom. Sometimes a baton sinister was added, sometimes a border. Strictly a natural son does not adopt his father's quarterings, unless such as are habitually borne conjoined, as the royal arms. The descendants of Charles II bear the whole arms with a baton sinister or border, those of William IV the lion. With the house of Bourbon the baton marked the cadets, the baton sinister the bastards. Sn Gilbert Talbot (1569), son of a bastard son of Sn Gilbert Talbot, was allowed Talbot and the usual five quarterings of the family, with a bend sinister over the whole, but this is unusual.

RULES OF BLAZON

To blazon a coat of arms is to describe it in the technical language of heraldry, and, although the works of the fathers of heraldic lore contain much irrelevant matter, and some confusion of arrangement, the rules of blazon, by whomsoever devised or perfected, are remarkable for their precision, brevity, and completeness. Great and successful one has been taken to produce clear and simple order, to avoid repetition, and to preserve a certain uniformity of arrangement through much complexity of detail. The technicalities arise in great measure from the use of terms once well known, and the language, as was to be expected, shows traces of the French and Franco-Norman channels through which the "gentle art" reached England.

First comes the description of the field, its colour, or the arrangement of the colours (if more than one), and the character of the partition lines when parted. Thus the "palmis inglorius alba" would be blazoned "he beareth argent." The coat of Walsgrave is per pale argent and gules, that of D'Eborac, earl of Gloucester, was "per pale dancette argent and gules."

Next follow the charges, and first those of most importance and nearest the field, their name, number, and position (if an animal, its attitude), and finally the colour. The principal charge is that which occupies the principal position. Thus Beakhouse of Kellet bore patty per saltire, azur and or, a saltire azure, England of England, azure, two ears of hagg or. Where the principal charge is an ordinary placed between smaller charges, it follows the field. Foliot, —or, a fess between two chevrons gules. The same rule holds where the ordinary is charged, as in Benthwaite of High Wyke, —gules, on a chevron argent three cross croslets fitchy sable, or when the two are combined, as Ken of Cessford, —vert, upon a chevron between two three unicorns' heads erased argent, hoined and armed or, as many mullets sable. Where the ordinary may be charged, but does not admit of being placed between charges, it is blazoned thus. Russell, —argent, a lion rampant gules, on a chief sable three escallops of the field. If the field be same of figures (*e.g.*, bespangled with them in regular order) they follow it. Pantonport, —argent, semée of cinquefoils gules, a lion rampant sable. Had the cinquefoils been on the lion instead of on the field the blazon would have run, argent a lion rampant sable, semée of cinquefoils gules.

The arrangement of common charges has already been explained (page 698, fig 85) —if one, central, if two, per pale, if three, 2 and 1, if more, as must be specified, as in Babbington (fig 9). Such diminutives as are borne in pairs follow their ordinary. Cludis, —argent, a bend between four crosses sable. To avoid repetition, if a sentence occurs twice reference is made to the first. Scott of Abbotsford, —or, two mullets in chief and a crescent in fess, azur, within an orle of the last, and so if the same number of oblique occurs twice, the words "as many" are used. Malng of Sealborough, —sinne, on a chevron vert between three hawks' jesses as many ones argent. Upton, who wrote in Latin, is put to strange shifts to express his meaning. He thus blazes the arms of Mortimer (fig 63) —

"Portant arma barbare, et caput semis palmatum et angulum, de azuro et erio, cum quadam serie, quousque in fine." In heraldic French this is, "il portoit barbe et ang chet pale, cunetes d'azur et d'or, et ung escu simple d'argent."

The following, from Menestrier, is the full blazon of the arms of the old kings of France —

D'azur quatre fleurs de lys d'or 2 and 1. Escu timbré d'un casque crevé d'un piéce de front, surmonté de ses lambrequins d'or, et d'azur, couronné de la couronne impériale Française, entouré des colliers des ordres du St Esprit et St Michel, soutenu par deux anges vêtus en Levites, la diminution des branches du fessu tenant chacun un braise de France, le tout placé sous un grand pavillon d'azur fleurdelysé d'or double d'armures, le cimble ayant d'or et couronné de la couronne impériale Française.

Le dit pavillon attaché à la hampe ou couronne du Royaume. Or du guet, "Montjoye St Denis." Devise, "Lion non laborat neque nunt," alluding to the operation of the Salvo law.

MARSHALLING ARMS.

Marshalling is the disposing or arranging of such coats of arms as have to be included in one shield. Blazoning deals with the particulars of each coat, marshalling with its position as regards other coats. Arms may be arranged per pale or impaled, or the shield may be divided into as many squares as may be required, when it is said to be quartered. The first coat, that of the bearer, may or may not be repeated in the last quarter as may be required to make up an even number of squares, which, though not necessary, is desirable.

For a time armorial bearings were purely personal, and intended to supply a want only felt by the wearer of armour. Hence, at first, females do not seem to have used them, and when a place was found for them on armorial seals, the coat was regarded as that of their father, and therefore not differentiated. For a time they seem to have had a separate shield. On one of the seals of Margaret of France, queen of Edward I., his three lions are displayed upon the point of her tunic, and on her right hand is a shield of France, on her left, one with a lion rampant. On the reverse is a shield of England, and around it, outside, a border of France. Margaret Bruce of Skelton married Robert de Ros. Her seal (1280) bears her effigy, somewhat defaced, so that nothing can be distinguished on her dress, but on her right is a shield of Ros, on her left one of Bruce.

A well-known seal, date about 1347, is that of Joan, daughter of Henry count of Bar, by Eleanor daughter of Edward I. by Eleanor of Castile. Joan was widow of Warren, earl of Surrey. Her seal is circular, with nine compartments. In the centre is Warren for her husband; above and below, England for her grandaunt; right and left are two barbels for her father. These four are on lozenges. In the four corner compartments are—(1) and (4) a lion for Leon, and (2) and (3) a castle for Castile, for her grandmother. This is a sort of rebellious quartering.

To this succeeded the allment to the wife of the sinister half of the husband's shield, displayed as though two shields had been divided vertically and united, omitting therefore the adjacent half of each coat. This is called dimidiation, and the shields so joined constitute an impalement. Another seal of Margaret of France illustrates this practice. In it half of England impales half of France. There is a good example of dimidiation in the tomb of William de Valence at Westminster, where Valence impales Clermont-Nesle, both dimidiated. An early German seal combines half an eagle with half a lion in this way. The arms of the Cinque Ports are remarkable examples of dimidiation. In each, the lions of England are dimidiated with the arms of the special Port. That of Hastings (fig. 126) is partly per pale dimidiated, Dexter, gules, three lions passant guardant or; Sinister, azure, three demi-bulks of ships argent. Sometimes one of the coats only was dimidiated. Eleanor (Montendré) was widow of Guy Fure. Her seal (1349) has a shield of Fure, a cross moline, and over it a bâton, dimidiated, impaling Montendré, a lion within an orle of trefoils. The lion is whole. The seal of Elizabeth, wife of Sir Lawrence Berkeley (fig. 126),—azure, a chevron or, between three crescents argent, impaling a lion rampant,—is a good example of an impalement without dimidiation (date 1392).

Usually the lady has the sinister side, but in the seal of Marion, wife of Sir William Dalsiel (1392) this is reversed, as it is in the impaled shield of John of Gaunt, where his wife, a daughter of Peter of Castile and Leon, has the dexter side. Dimidiation is not applicable to all coats. A canton on the sinister coat would be lost, and a chevron be converted into a bend. The tressure, orle, and border were usually, not always, dimidiated; and although this form of im-

plement has fallen into disuse, these charges are still borne dimidiated, as may be seen with the border and tressure on the tomb of Mary, queen of Scots.

When the lady was the last of her race, various modes were devised for the conservation of her name and arms. Thus on the death (1193) of Robert de Lacy, last of the line of Pontefract, John, constable of Chester, half-brother to Robert by his mother, took the name and arms of Lacy, and was ancestor of the earls of Lincoln of that name. In the same century Isabel, heiress of Earl Warren, married Hamelin Plantagenet, who took the name, and their children bore the arms of Warren; and so with the Mandevilles, earls of Essex.

Sometimes a coat was compounded of the two families. Thus Mr Planché is of opinion that the bend was added to the paternal coat of Bohun, on the marriage with the heiress of Milo, earl of Hereford. Scottish seals show many examples of such composition. Eustace Colville, widow of Reginald le Chein, in 1316, bore a cross moline, square pierced, for Colville, between four cross crosslets fitchy for Chein. About the middle of the 14th century began the practice of placing the arms of females upon a lozenge. As early as 1347 Elizabeth D'Arcy so bears her arms, as in 1356 does Maud Fitz Rym. The seal of Joan Beaufort, widow of James I., affords the earliest Scottish example.

The first step towards a regular method of preserving heraldically the memory of a family extinct in the male line seems to have been taken in Spain by a process now known as quartering. Eleanor of Castile, queen of Edward I., has upon her tomb a shield divided into four quarters, in the first and fourth of which is Castile, and the second and third Leon. The practice, though not finally regulated, was approved, for on the seal of the "She-wolf of France," queen of Edward II., the shield is quartered (1) England, (2) France, (3) Navarre, (4) Champagne, taking up confusedly the arms of husband and wife, as they also are upon the shield of Philippe of Hainault, queen of Edward III., who bore quarterly, (1) and (4) England, (2) and (3) Hainault and Holland. A very early instance of regular quartering occurs in the will of Humphrey Bohun, earl of Hereford, dated 11th August 1310, by which he bequeaths a court-point quartered with the arms of England and Bohun. This is five years before the accession of Edward III., and makes it probable that the quartered coat of William de Foix at Winchester is original.

Under Edward III. quartering came into general use. The King led the way by quartering France and England, and the earl of Pembroke followed, quartering Hastings and Valence. John Hastings, his son, commented on his shield his father's match with Ann daughter of Margaret, duchess of Norfolk, a co-heir of Thomas of Brotherton, and this affords an early instance of the precedence often given in quartering to the royal arms. John Hastings bore quarterly of four—(1) and (4) Brotherton (Plantagenet), (2) Hastings, (3) Valence; and, on another example—(1) and (4) Brotherton, (2) and (3) Hastings quartering Valence. This latter arrangement of sub-quartering shows a considerable advance in the system. Henry IV. combined quartering with dimidiation in a shield long preserved in the window of Christ Church, Newgate, which bore France and England quarterly, impaling France with a bend gobony, and Navarre quarterly dimidiated, for Joan of Navarre. In this case the 1st and 3d quarters were removed, and the sinister bearings thus reduced to what may be better blazoned as party per fess, (1) Navarre, (2) France. The French sometimes quartered diagonally, called "Scartile on sautoir." The old kings of Sicily thus divided their shield: party per saltire, (1) and (4) Aragon, (2) and (3) Swabia. This plan never found favour in England, where

FIG. 126.

FIG. 126.

a regular system of quartering sprang up, and has continued in use. A quartered shield, though of no special family, is shown by fig. 12.

At first the arms of an heiress were impaled by her husband, but latterly they were placed on a central inescutcheon designated an escutcheon of pretence. The

children divided the shield into four quarters, and placed the paternal coat 1 and 4, the maternal 2 and 3. If a second heiress came in, she was placed in No. 3; if a third, in No. 4; if more, the shield was divided as required. The following pedigree will explain the system. In it all the descents that did not bring in an heiress are omitted.

4. Walteran de Newburgh

1. Ralph de Monthermer. 5. Wm. Manduit=4. Alice.

2. John de Montacute=1. Margaret. 6. Wm. Beauchamp=5. Isabel. 7. Hugh le Despenser=8. Alianor de Clare.

3. Richard Neville=2. Alicia.

6. Richard Beauchamp=7. Isabel.

8. Richard Neville=6. Anna.

9. Geo. D. of Clarence=3. Isabel.

10. Richard D. of Gloucester (Richard III.)=3. Anna.

1. Monthermer: or, an eagle displayed vert.
2. Montacute: argent, three fusils conjoined in fess gules.
3. Neville: gules, a saltire argent.
4. Newburgh: chequy or and azure, a chevron ermine.
5. Manduit: argent, two bars gules.
6. Beauchamp: gules, a fess between six cross crosslets or.
7. Le Despenser: quarterly, 1 and 4 argent, 2 and 3 gules, a fess or, over all a ribbon saffron.
8. De Clare: or, three chevrons gules.
9. Clarence: quarterly France and England, a label of three points argent, each charged with a canton gules.
10. Gloucester: quarterly France and England, a label of three points ermine, on each point a canton argent.

The armorial bearings of each generation will be as follows:—

1. Monthermer alone.
2. Montacute impaling Monthermer.
3. Neville impaling quarterly, 1 and 4 Montacute, 2 and 3 Monthermer.
4. Newburgh alone.
5. Manduit impaling Newburgh.
6. Beauchamp impaling quarterly, 1 and 4 Manduit, 2 and 3 Newburgh.
7. Le Despenser impaling De Clare.
8. Beauchamp: quarterly of four—1 and 4 Beauchamp, 2 Manduit, 3 Newburgh; impaling quarterly of four—1 and 4 Le Despenser, 2 and 3 De Clare.

3. R. Neville: quarterly of four—1 and 4 Neville, 2 Montacute, 3 Monthermer; impaling quarterly of six—1 and 6 Beauchamp, 2 Manduit, 3 Newburgh, 4 Le Despenser, 5 De Clare.
6. George, duke of Clarence: France and England quarterly, impaling Isabel Neville quarterly of nine—1 and 9 Neville, 2 Montacute, 3 Monthermer, 4 Beauchamp, 5 Manduit, 6 Newburgh, 7 Le Despenser, 8 De Clare.

The above, being a well-known and very noble pedigree, has been selected to illustrate the system of quartering, which is explained by the shield (fig. 127), thus emblazoned:—

1. George, duke of Clarence; 2. Neville, who brings in 3. Montacute; 4. Monthermer; 5. Beauchamp, who brings in 6. Manduit; 7. Newburgh; 8. Le Despenser; 9. De Clare.

Unfortunately the several bearers of these arms were fanciful, and sometimes gave precedence to one and sometimes to another coat, and indeed never used the whole, which would have crowded their shields and caparisons. The four woodcuts, figs. 128-31, will illustrate this.

Fig. 127.

FIG. 128.—Seal of Richard Beauchamp, earl of Warwick.

They represent the great seals of Richard Beauchamp, earl of Warwick, who married Isabel le Despenser, and Richard Neville, earl of Warwick, who married Anne Beauchamp.

Beauchamp quarters the arms of his wife, but makes De Clare impale Le Despenser, while he himself impales Newburgh. The

FIG. 129.—Commemorial of Richard Beauchamp, earl of Warwick.

blazon would thus be quarterly of four grand quarters—1. and IV., Beauchamp impaling Newburgh; II. and III., De Clare impaling Le Despenser (fig. 128). On the commensal (fig. 129) the earl bears on his shield Beauchamp and Newburgh quarterly, and on his caparison Beauchamp, Newburgh, De Clare, and Le Despenser also quarterly.

"1. *Patrit informatio linea De la Pole, et pume quoniam finit mita qd de la Pole, 2do Quoniam finit ejusdem pte et mti, 3do Quoniam finit tunc Thomas Chaucer son mter Alene, et 4to Quoniam finit tunc familiarum Pole, Chaucer, et aliam, qm apponunt in superioribus localum, indicat, aut patris cum debitis coloribus, aut scriptura, per amonum hnt et coloris."*

This sort of escutcheon at once placed before the eye the heraldic history of the family for four generations.

Bishops, deans, kings-at-arms, and the heads of certain corporations wear their paternal arms impaled by those of their office. No provision is made for the wife.

Single women or widows bear their arms upon a lozenge. Widows, and priestesses use their husband's supporters. Peccatores, in their own right use their own. But no lady uses crest or motto.

A commoner who marries a peeress in her own right uses two shields. On the dexter she has her own arms with those of her wife on a scutcheon of pretence ensigned with her coronet, on the sinister the lady's arms alone on a lozenge with supporters and coronet. If the lady be only a dowager peeress, and not an heiress, there are also two shields. On one the husband impales her arms in the ordinary way, on the other are the lady's arms, &c., as a widow, impaled by those of her first husband, with his supporters and coronet, but no crest, and the arms in a lozenge.

A baronet of England or Ireland bears a sinister hand couped gules on an unequipped or a canton. It is blazoned "argent, a sinister hand, couped at the wrist and armant, gules." Those of Nova Scotia bear argent on a shield of pretence, Scotland ensigned with a crown.

Fig. 171

Baron of Ridgrave, the premier baronet, bears gules, on a chief argent two mullets placed sable (fig. 138).

A knight of an order surrounds his shield, usually a collar, with the ribbon and motto of the order. If invited he takes a second and sinister shield, and thereon impales his wife's arms, the whole within a plain ribbon.

A widower marrying a second wife divides his shield twice per pale, and places his own arms in the centre, his first wife's on the dexter, his second's on the sinister side. For a greater number there is no structure. A certain Sir George Clifton who survived seven wives, placed himself in the centre of the shield, and his wives around him. The widow of two husbands may divide her lozenge twice per pale, and place her first husband on the dexter side, her second in the centre, and herself in the sinister place, or she may divide the dexter half on her lozenge per fess, and place the arms of the first husband above, and those of the second below.

APPENDAGES

These include whatever is borne outside the shield, as the crest, badge, motto, supporters, helmet, coronet, and some other additions. Strictly speaking, armorial bearings are confined to the contents of the shield, and heralds have never regarded the appendages as of the same importance.

The *Crest* was the ornament of the *hordpiece*, and afforded protection against a blow. In early rolls of arms it is not noticed. In early seals when it appears it is rarely heraldic. Richard I. wears a sort of fan-shaped ornament, but has a lion passant guardant on the front of his helmet. Edmund Crouchback in 1290 uses distinctly a crest. Of fourteen seals of horsemen in complete armor appended to the barons' letter to the pope in 1301, three only have regular crests, although many have plumes. The three are—Thomas earl of Lancaster and Ralph earl of Gloucester, men of high rank, and Sir John St. John, a great military commander. In the 14th century they became general. In 1355 the count of Hainault presented to Edward III. "unam galeam

protosam cum apparatu quam idem comes solebat in capite suo gestare." This was the crest of the eagle seen on the count's seal, and which the king regarded as the fons of Annan to Montagu, earl of Salisbury. Edward himself used the lion, which has continued to be the crest of the English sovereigns. Adam de Blancow (1366-7) had a grant of arms and crest of the Greyhound bearings from William, lord of Greytoste.

Richard Beauchamp, earl of Warwick (died 1439), rests his feet upon the crests of the bear and griffin for Warwick and Montagu. His paternal crest, the swan's head out of a ducal coronet, is placed upon his helmet, beneath his head. The dragon and wyvern were common crests, and the plume of feathers is still used by Scropes and Courtenay. Ralph, Lord Neville of Raby, used the bull's head in 1355, Hastings, a bull's head in 1347. Crests were, like arms, allusive. Grey of Wilton used a "grey" or badge, Lord Welles, a bucket and chain, Botreaux, a buttice. The crest was sometimes placed on a ducal coronet, sometimes used out of a wreath or touse of the colours of the arms. The coronet below the crest is not a mark of rank. In Chichester cathedral is the crest of Davidson, a bird issuing out of an earl's coronet. This, however, is rare, the coronet so used is generally ducal. Crests were granted and bequeathed. In Germany it is usual to bear the crests of the "near quarters" or some of them. This of course is inconsistent with the actual use of the crest in war. At first crests were confined to persons of rank, but they have long been included in every grant of arms. In England two or more can only legitimately be borne when the bearer has from the crown a grant of name and arms in addition to his own, as Chetwynd-Talbot, Fitz Alan-Howard.

With the crest is usually combined some flowing drapery known as the "panache," "mantling," or *lambequin*. This seems to have served to protect the helmet from heat and dust, and was also ornamental. It is represented in great perfection on tombs of the 15th and 16th centuries, commonly of some brilliant colour with a lining and tassels. The tilting helmet which supports the head of the *chiff* of Humphrey de Bohun (died 1287), at Gloucester, is accompanied by a grand early specimen of the lambrequin.

The *Badge* or *Cognissance* was not worn on the helmet, but displayed upon the persons of the retainers of great barons, and sometimes used to ornament the shield or seal. At the celebrated judicial combat at Coventry before Richard II. in 1385, Henry of Lancaster appeared with his housings of blue and green embroidered with swans and antelopes, his badges, and Mowbray had housings of crimson velvet, embroidered with silver lions and mulberry trees, his badges. The bear was the Beauchamp badge, derived possibly from Uise D'Abet. They also used the ragged staff and the combination of the two.

The seal of Richard III., 1481, as lord of Glamorgan, exhibits the bear as a supporter, and the countess repeats it as a badge (figs. 134, 135). This seal well illustrates various heraldic points. Its blazon is per pale, baron and femme, baron, France modern and England quarterly, over all a label of three points, femme, per fess, Beauchamp, and chequy, on a chevron five pale's heads passant fleurs-de-lis, for Newburgh combined with Cantelme. The same arms are repeated on the shields and caparisons of the countess. Richard married Anne Neville, but the Neville saltire does not appear, only the arms of Beauchamp and Newburgh, both of whom were earls of Warwick.

"The rampant bear chained to the ragged staff" was inherited by the Nevilles and Dudleys, and granted about 1759 to the Grevilles as the owners of Warwick castle. Pelham used a buckle, Percy a crescent, Boucher, Bowen, Daere, Homeage, Hungerford, Lacy, Stafford, Wake, and

Harrington used the knots that bear their names. Gower designates the great nobles of his day by their badges, as is done in the following satirical lines written about 1449:—

The robe is ded, the swan¹ is goon,
The fiery cross² hath lost his light,
Therefore England may mak greet rouse,
Were not the helpe of God Almight.
The castell³ is wonne, where care begoun
The portecolys⁴ is leyde a down;
Yclosed we have oure Vyllette batte⁵,
That keppe us from many stormys browne.
The white lim⁶ is leyde to slepe,
Thorough the envy of the aye dogges⁷,

and so on, through interminable further instances.

The Scottish clans wore native plants for their badges: Chisholm, the alder; Menzies, the ash; McIntosh, the box, &c.

The Motto.—In times when each chief tenant under the crown brought his own tenants into the field, and led them,

distinct war-cries were common. The royal cry was "St George for England." The French cried, "Montjoye St Denis," the *cri de guerre* of Bauffremont was their name; that of Barr, "Au feu"; Seyton, "St Bennet and Set on." The common Highland cry or slogan was "Claymores"; that of the Medici, "Palle, palle," alluding to their arms. The motto succeeded to this (1291); Brace of Ammandale used "Eato fortis in bello"; Courtenay, "Passez bien devant"; Hastings, "Honourans me honorabo"; Kirkpatrick used the crest of the bloody dirk with the motto "I mak sickers." The Warren motto, alluding to the earls' resistance to the "quo warrantum," was "tenebo;" Vernon, "God save the Vernon," ill exchanged for "Vernon scupper vint." The Scottish borderers, who lived by harrying their neighbours by moonlight, used stars and crescents for their arms, and such mottos as "Reparabit cornu Phœbo" for Scott of Harden, or "Watch weel" of Halyburton. In modern times Sir Dudley Ryder died while his patent of peerage

FIG. 134.—Seal of Richard III.

was under seal. It was given to his son, who adopted as a motto "*Fides servata cineri*."

Supporters are now placed on either side of the shield, and are usually animals or human figures. They seem to have arisen from the ornaments introduced by the seal engraver, and became heraldic with the practice of quartering. The seal of Edmund Crouchback bears a shield flanked by two wyverns, probably ornaments. That seal (1388) and the seal of Henry of Lancaster in 1300 contain both crest and helm, lambrequin and supporters. The seal of Catherine, queen of Henry IV., has two antelopes, and her husband as prince used two swans. At Naworth the family supporters, of gigantic size, support the principals of the roof of the hall. Under the house of Tudor many families of knightly rank, as Babington, Stanhope, and Luttrell, used supporters, but at this time supporters are only granted to peers, knights of the garter, grand crosses of the bath, Nova Scotia baronets, and a few private persons who hold them by prescription. In Scotland they are used by heads of clans and by a few lowland families. Fletcher of Saltoun uses two griffins.

Another appendage is the *Eagle*, upon which some North Wales families place their shields, and the double-headed variety so used by nobles of the Holy Roman empire.

¹ Duke of Bedford.

² Bohun, earl of Gloucester.

³ Duke of Exeter.

⁴ Rouen.

⁵ Beaufort, duke of Somerset.

⁶ Cardinal Beaufort.

⁷ Duke of Norfolk.

⁸ Duke of Suffolk.

FIG. 135.—Countersail of Richard III.

The *Livery* has long lost its early signification, and is used only for the dress of the retainers in their lord's colour. At Richard III.'s coronation 8000 badges of the white boar were wrought upon liveries of fustian. A statute of Henry IV. forbade the use of liveries under heavy penalties, but they reappeared in the Wars of the Roses. Richard III. used "collars of livery," but these were for persons of rank. One remains upon a Neville cfigy at Brancepeth.

Crowns, Coronets, and Symbols of Rank.—The crown is the head attire of a sovereign prince. It is usually closed at the top by four arched bars called diadems, and surmounted by a globe and cross. Edward IV. is said to have first closed the English crown. That now in use is a circle of gold, jewelled, edged above with crosses patée and fleurs-de-lis alternate, and closed above with four bars and the cross and globe called in Germany the Reichsapfel (fig. 136). Since the Restoration the crown of the Princes of Wales has been surmounted by two bars, also with the Reichsapfel (fig. 137). They also use the plume of three ostrich feathers, with the words "Ich dien," adopted by the Black Prince (fig. 138). Figs. 139 and 140 give representations of the imperial crown of Austria, and the crown of the old kings of France. The Pope places three crowns over his mitre or tiara (fig. 141), said to have been solemnly assumed in 1205, 1335, and 1411. The crown imperial of Charlemagne may be seen on a sarcophagus of pretence on the arms of Hanover, as the

elector's badge of arch-treasurer. The doges of Venice and Genoa bore a peculiar cap or toque, seen in Greek statuary, and upon the figures on the arch of Constantine

FIG. 136—Crown of England

FIG. 137—Crown of the Prince of Wales

FIG. 138—Crown of Austria

FIG. 139—Crown of Austria

The coronet is the head attire of a noble. In England those of princes of the blood are bordered with crosses

FIG. 140—Crown of a Prince (old)

FIG. 141—The Pope's Crown

FIG. 142—The Sultan's tiara

patée and fleurs-de-lis upon a regulation of 13 Charles II (fig. 143). The princesses alternate the same ornaments with strawberry leaves (fig. 144).

The coronet of a duke is bordered with eight strawberry leaves (fig. 145), that of a marquess with four alternating with four pearls placed on low points (fig. 146). An earl's coronet has eight strawberry leaves alternating with eight pearls upon tall points (fig. 147). The viscount borders his coronet with an indefinite number of pearls,

FIG. 145

FIG. 146

FIG. 147

FIG. 148

set close upon the rim (fig. 148). The baron's coronet, granted to the order by Charles II, carries six pearls placed on the rim at equal intervals,—four being seen at once (fig. 149). These coronets are all lined with ermine, and encircled with jewels. On occasions of state, when not worn by the peer, they are carried before him on a cushion. The oldest sons of peers above the rank of viscount wear the coronet due to their father's second title. The crowns of the kings, at arms are of gold, bordered with and encircled by the motto "Misereatur, Domine." The ducal, as an ancient form of coronet, is often used without reference to rank, as the base for a crest. It was so used by Sir Simon de Felbrugge in 1442.

A bishop has neither crest nor coronet, but assigns his arms with a mitre. The bishops of Durham, while pontifices, placed their mitre in a ducal coronet, as—though without authority—do the archbishops (fig. 150). The Borkley crest is a mitre. The ancient mitre was low, and of linen stiffened with vellum. The central band and the margin, embroidered with fleurs-de-lis or other patterns, were called the ophreys. The pendulous side ribbons were the "infule." Prelates of the church of Rome encircled their shields with a hat, the tassels of which indicate their rank. A cardinal has four rows of red tassels, arranged 1, 2, 4, 8, or 15 on each side, an archbishop the same, but green. A bishop has three rows, an abbot two, the abbot's hat is black. Prelates and legates place a patriarchal cross in pale behind their shield.

The *Helmet* also indicates the rank of the wearer. It

is placed above the shield, and beneath the crest. The sovereign and the royal family bear the helmet full-faced or affrontée with six baits, all of gold (fig. 151). Those of dukes and marquises are of gold with five steel baits (fig.

FIG. 151

FIG. 152

FIG. 153

FIG. 154

152). The lesser nobles have silver helmets borne in profile with gold ornaments and four silver baits. Those of baronets and knights are of steel, full faced and open (fig. 153). An esquire's helmet is of steel, represented in profile, with the visor closed (fig. 154). These distinctions were probably introduced after the Restoration.

The *Mantling* is a sort of cloak or mantle of fur extended behind the shield, and sufficiently ample to include the whole achievement. Those of sovereigns are of gold doubled with ermine, and are called "pavillons." Peers' mantlings are of crimson velvet, doubled with white fur and barred with ermine spots, a duke has four baits, a marquess three and a half, an earl three, a viscount two and a half, and a baron two. Commoners use red mantlings lined with white fur. The prior of St John, whose place was on the right of the temporal barons, used a sable mantling doubled with murrey. The pavilion of France was of blue velvet, powdered with gold fleurs-de-lis, and lined with ermine. Such a mantling may be seen behind the arms of Beaumont in Rothley Temple chapel, in right of their descent from the blood-royal of France.

Certain offices of state accompanied them armorial shields with exterior marks of their rank. The Earl Marshal placed two tunccheons saltwise behind his shield, tipped above with the arms of England, and below with his own arms. His deputy places one tunccheon in bend dexter.

In Scotland the Lord High Constable, the earl of Eriol, places on either side of his shield an arm issuant from a cloud, and grasping a sword. Under the old monarchy the French colonels commanding placed the standards of their regiments saltwise behind their shields.

The Lords High Admiral have been variously distinguished. Thomas de Berkeley bears on his banner a collar of tritons. Thomas, duke of Exeter, sealed with a ship and his arms on the mainsail. The anchor in some form or other was a common emblem.

Merchants' marks are scarcely heraldic, though they took the place of arms with the trading classes. They were usually monograms of the name or initials. They were protected by law as marks on goods, and are seen on merchants' tombs and sometimes in architecture.

FUNERAL ESUTOCHIONS

Some of the most valuable records in the College of Arms are the certificates of funerals conducted under their superintendence and authority. These gorgeous and expensive ceremonies have happily fallen into disuse, save on very rare occasions, and for royal persons or eminent public characters. The last private funeral conducted with anything like the ancient ceremonial was that of Charles, earl of Shrewsbury, in 1828. All that is now usual is the suspension of a shield of arms in a large black lozenge-shaped frame called a hatchment or achievement against the wall of the house of the deceased. It is usually placed over the entrance at the level of the second floor, and remains for from six to twelve months, when it is removed to the parish church. Even this custom, scarcely consistent with lying in hired houses and burying in cemeteries, is falling into disuse, though still not uncommon.

FIG. 150

If for a bachelor, the hatchment bears upon a shield his arms, crest, and other appendages, the whole on a black ground. If for a single woman her arms are represented upon a lozenge, bordered with knotted ribbons, also on a black ground. If the hatchment be for a married man (as in fig. 156), his arms upon a shield impale those of his wife; or if she be an heiress they are placed upon a scutcheon of pretence, and crest and other appendages are added. The dexter half of the ground is black, the sinister white.

For a wife whose husband is alive the same arrangement is used, but the sinister ground only is black. For a widower the same is used as for a married man, but the whole ground is black; for a widow the husband's arms are given with her own, but upon a lozenge, with ribbons, without crest or appendages, and the whole ground is black. When there have been two wives or two husbands the ground is divided into three parts per pale, and the division behind the arms of the survivor is white. Colours and military or naval emblems are sometimes placed behind the arms of military or naval officers. It is thus easy to discern from the hatchment the sex, condition, and quality, and possibly the name of the deceased.

In Scottish hatchments it is not unusual to place the arms of the father and mother of the deceased in the two

FIG. 156.

FIG. 159.—Arms of the Dukes of Marlborough.

The above figure represents the armorial achievement of the dukes of Marlborough, princes of the Holy Roman Empire and of Mindelheim in Swabia. The arms are quarterly—1 and 4, Churchill, white, a lion rampant; and on a chief argent a castle argent; 2 and 3, Spencer, quarterly argent and gules: in the second and third a fess or, over all on a bend sable 5 escallops of the first; in chief, as an augmentation, upon an escutcheon of pretence argent a cross of St. George, charged with six inescutcheons azure, 3 fess-a-dexter or; the whole contained within the garter, ensigned with a ducal coronet, and placed upon the breast of an imperial eagle. Crests—1, Churchill, a lion couchant guardant argent, supporting with his dexter paw a banner; 2, Spencer, a dexter hand armed, assumed of the first, staff or; 3, Spencer, out of a ducal coronet a griffin's head argent, armed or, gorgeed with a her gemelle gules, between two wings expanded of the second. Between the crests the closed crown of a prince of the empire. Supporters—two wyvrens argent, wings expanded. Motto—Fidel pro desidichon.

lateral angles of the lozenge, and sometimes the 4, 8, or 16 genealogical escutcheons are ranged along the margin.

Undertakers are fond of substituting "In oculo quies" or some such commonplace for the family motto. This is irregular.

The literature of heraldry commences with the treatises of Sassoferrato about 1368, De Fosse in the reign of Richard II., and Upton about 1441, all written in Latin and printed by Sir E. Rysshe in 1664. They are followed by the *Traktat von den Wapen*, written by Dams Juliana Berners, prioress of Boywell, and printed in 1486. These, especially those of Upton and Dams Juliana, are valuable. The lady writes in a mixture of early English and Latin, but her descriptions are intelligible and copious. These writers were followed by a crowd of others, of whom the chief were Gerard Leigh, Ferne, and Morgau, who wrote in the latter half of the 16th century. Their great aim was to elevate their subject by tracing back the use of armories to the patriarchs and heroes of Jewish and pagan antiquity, whom they invested with coats of arms on the type of those used by Norman barons. There are traces of this folly in Dams Juliana, but it reached its height in the writings of her successors, and was not quite extinguished when Guillim wrote his *Display of Heraldry* in 1610. Guillim, whose work is still a standard, wrote in English, but as late as 1664 and 1688 Spelman, in his *Aspilogia*, and John Gibbon strove hard to restore the use of a dead language upon a subject to which it was eminently unsuitable. In 1723 and 1780 were published the excellent volumes of Nislet, chiefly relating to Scotland, and of Edmondson, whose list or ordinary of bearings was long very useful to those who seek to identify the mine to which a coat belongs, until superseded by the very laborious and far more complete work of Papworth.

Recently the same critical spirit that has pervaded the works of our historians has been applied, with equal diligence to the whole subject of heraldry; a number of authors, led by Pucknell, Boutell, Seton, Nichols, and Lower, have set aside all the fabulous pretensions and baseless assertions of the earlier writers, have sifted the old evidence and adduced much that is new. The whole subject of heraldic and quasi-heraldic seals has been brought under notice by the publication of Laing's fine plates of Scottish seals; and it may truly be said that the real origin and growth of the use of armorial bearings is placed before the reader in the books of these writers in a truthful and most attractive form.

(G. T. C.)

HERAT is a city of great interest both historically and geographically, and is of even greater interest politically, its importance at the present day being indicated by its popular designation of the "key of India." Its origin is lost in antiquity. The name first appears in the list of primitive Zoroastrian settlements contained in the *Vendidad Sade*, which, however, like most of the names in the same list,—such as *Sughda* (Sogdiana), *Mowâ* (Meiv or Margus) *Haraputs* (Araclotus or Arghandab), *Haetmant* (Ectymander or Helmand), and *Rughra* (or Argha stân),—it seems to apply to the river or river basin, which was the special centre of population. This name of *Haraputs*, as it is written in the *Vendidad*, or *Haraputs*, as it appears in the inscriptions of Darius, is a cognate form with the Sanskrit *Sarasvati*, which signifies "a river," and its resemblance to the ethnic title of Aryan (Sansk. *Ârya*) is purely fortuitous, though from the circumstance of the city being named "Aria Metropolis" by the Greeks, and being also recognized as the capital of Ariana, "the country of the Aryans," the two forms have been frequently confounded. Of the foundation of Herat (or Hêrât, as it is still often called) nothing is known. We can only infer from the colossal character of the earth-works which surround the modern town, that, like the similar remains at Bost on the Helmand and at Ulân Rohât of Ariacostia, they belong to that period of Central-Asian history which preceded the rise of Achaemenian power, and which in Grecian romance is illustrated by the names of Bactilus, of Hercules, and of Semiramis.

The natural advantages of Herat are mainly due to its river, which, rising in the high uplands 350 miles to the eastward, where the Koh-i-Bâbâ, the prolongation of the Hindu-kûsh, bifurcates into the two parallel ranges of the Sufid-koh or "white mountains" to the north and the Syah-koh or "black mountains" to the south, passes in its upper part of its course through a succession of rolling downs of the finest pasture land, and lower down traverses a more contracted valley, unploughed, however, throughout with smiling villages and orchards, till it reaches the eastern limit of the alluvial plain of Herat. Here at the present day nine large canals (in former times there were twenty) carry off the waters of the Herat-rûd for the irrigation of the circumjacent plain, which on a rough calculation may be said to contain nearly 400 square miles of land available for cultivation. M. Khankoff, who visited Herat in 1908, observes that nowhere in the East,—not even at Samarcand or Bokhara or Tashkent, which are at least supposed to be carried to perfection,—had he seen water-works constructed with so much skill, or maintained with so much care, as in the valley of the Herat-rûd, and he adds that, although at the period of his visit nine tenths of the villages of the plain, which in ordinary times amount to nearly 500, were partially in ruins and the adjoining fields laid waste, the cereal produce of the remaining lands was still far in excess of the wants of the settled inhabitants. The Herat-rûd, passing between 3 and 4 miles to the south of Herat, where it is spanned by a magnificent bridge of twenty three arches, called the *Fâh-â-Mâdâ*, continues its course westward to the great empty of this rich and fertile plain, it then turns north through an arid country for some 200 miles to Samkha, leaving two small streams from the west, the Ab-i-Jâm and Ab-i-Meshad, and forming the territorial boundary between Persia and Afghanistan. As the Herat-rûd is formed of the converging drainage of the Sufid-koh and Syah-koh ranges, and its volume thus depends on the extent of snow that falls in the mountains, it is impossible to define with any exactitude the limit of its northern course, but in ordinary seasons water is rarely found in the river bed beyond Saialkha, and never does the stream penetrate to the northward of a line uniting Abberd and Merv,

and it is of the more importance to note this geographical feature, as in many of our modern maps the line of the Herat-rûd, or Tejend, as it is called in its lower course, is prolonged through the desert 200 miles to the north-westward of Saialkha.

The city of Herat is in 31° 22' N lat and 62° 9' E long. It is very centrally situated, great lines of communication radiating from it in all directions—southward to Samtân (200 miles), south-eastward to Kandahar (370 miles), eastward to Cabul (550 miles), northward by Mymenah to Bokhara (600 miles) and by Merv to Khiva (700 miles), while to the westward four routes lead into Persia, by Farbat to Meshed (315 miles), and by Bârgend to Kermân (400 miles), to Yazd (300 miles), or by Isfahân (600 miles). The city forms a quadrangle of nearly a mile square (more accurately about 1600 yards by 1500 yards), on the western, southern, and eastern faces the line of defence is almost straight, the only projecting points being the gateways, but on the northern face the contour is broken by a double outwork, consisting of the *Ah* or citadel, which is built of sun-dried brick on a high artificial mound within the enceinte, and a lower work at its foot, called the *Ah* *now*, or "new citadel," which extends 100 yards beyond the line of the city wall. That which distinguishes Herat from all other Oriental cities, and at the same time constitutes its main defence, is the stupendous character of the earthwork upon which the city wall is built. This outwork averages 250 feet in width at the base and about 50 feet in height, and as it is crowned by a wall 25 feet high and 14 feet thick at the base, supported by about 150 semi-circular towers, and is further protected by a ditch 45 feet in width and 16 in depth, it presents an appearance of imposing strength. Whether the place is really as strong as it looks has been differently estimated.

General Ferrier, who resided for some time in Herat in 1846, states that the city is nothing more than an immense rampart, and gives it as his opinion that as the line of wall is entirely without flanking defences, the place could not hold out for twenty days against a European army, and M. Khankoff, who, though not a professional soldier, was a very acute observer, further remarks that the whole interior of the city is dominated from the rising ground at the north east angle, while the water supply both for the ditch and the city would be at the mercy of an enemy holding the outside country, the wells and reservoirs inside the wall, which would then be alone available, being quite inadequate to the wants of the inhabitants, but on the other hand all experience testifies to the defensibility of the position. Not to speak of the sieges which Herat sustained at the hands of Jenghiz Khan, of Timur, and of Ahmed Shah, we have only to remember that in 1837 the Afghans of Herat beat off the continuous attack for nearly ten months of a Persian army of 35,000 regular troops, supported by 50 pieces of artillery, and in many cases directed and even commanded by Russian officers. The truth seems to be that Herat, though in its present state quite unfit to resist a European army, possesses great capabilities of defence, and might by a skilful adaptation of the resources of modern science be made almost impregnable. A British engineer officer, Major Sanders, calculated in 1840 that at an outlay of sixty or seventy thousand pounds, which would include the expense of deepening the ditch, cleaning the glacis and esplanade, providing flanking defences and repairing the walls, &c., throughout, Herat might be rendered secure against any possible renewal of the attack by Persia, but of course if an attack by a well appointed European army were anticipated, more extensive preparations for defence would be required, including probably the erection of two independent forts on the high ground at Mossallâ and Thaleh-beng.

The city possesses five gates, two on the northern face, the Kutab-chak near the north-east angle of the wall, and the Malik at the interior angle of the Ak-i-nay, and three others in the centres of the remaining faces, the Irak gate on the west, the Kandahai gate on the south, and the Khushk gate on the east face. Four streets called the *Chakab-sah*, and running from the centre of each face, meet in the centre of the town in a small dense quadrangle. The principal street runs from the south or Kandahai gate to the market in front of the citadel, and is covered in with a vaulted roof through its entire length, the shops and buildings of this bazai being much superior to those of the other streets, and the merchants' caravanserais, several of which are spacious and well built, all opening out on this great thoroughfare. Near the central quadrangle of the city is a vast reservoir of water, the dome of which is of bold and excellent proportions. It is stated by General Foyat to have been constructed by command of Shah Abbas, and to be a *chef d'œuvre* of its kind. It is supposed to contain above a twelve months' supply of water for the entire city, but, as M. Khanikoff observes, it is within easy motor range of the high ground at the north-east angle of the city, and might thus be destroyed by a few well directed shells, in which case the ruins of the dome would fill up the basin and the water supply would be lost. The only other public building of any consequence in Herat is the great mosque or *Meydan-i-Jama*, which comprises an area of 600 yards square, and must have been a most magnificent structure. It was erected towards the close of the 15th century, during the reign of Shah Sultan Husseini of the family of Timur, and is said even perfect to have been 465 feet long by 275 feet wide, to have had 408 cupolas, 180 windows, 444 pillars, and 6 entrances, and to have been adorned in the most magnificent manner with gilding, carving, precious mosaic, and other elaborate and costly embellishments. Now, however, it is falling rapidly into ruin, the ever changing provincial governors who administer Herat having neither the means nor the inclination to undertake the necessary repairs. Neither the palace of the Cheragh within the city wall, which was the residence of the British mission in 1840-41, nor the royal quarters in the citadel deserve any special notice. At the present day, with the exception of the *Chakab-sah*, where there is always a certain amount of traffic, and where the great diversity of race and costume impart much liveliness to the scene, Herat presents a very melancholy and desolate appearance. The mad houses in rear of the bazai are for the most part uninhabited and in ruin, and even the burnt brick buildings are becoming everywhere dilapidated. The city is besides one of the filthiest in the East, as there are no means of drainage or sewerage, and garbage of every description lies in heaps in the open streets.

With regard to the population, it fluctuates so rapidly, according to the circumstances of the period, that it is impossible to give any estimate of its normal strength. When Christie visited the city in 1800 it was in a very prosperous condition, having been undisturbed for fifty years, and was supposed to contain 100,000 inhabitants. A Conolly in 1828 reduced the numbers to 45,000. Before the Persian siege in 1837 the population was estimated at 70,000, but at the close of the war 6000 or 7000 were all that remained. In 1846, at the time of General Foyat's visit, the numbers had increased again to 22,000, and continued to increase to the time of the capture of the place by Dost Mahomed Khan in 1863, when there was at least 50,000 inhabitants within the walls. Since that time Herat has been a mere provincial city governed from Cabul, and its average population has ranged between 20,000 and 30,000, within which limits must be confined its present estimate.

The maximum population of which the ancient world seem to be capable may be put at Christie's estimate of 100,000, and it is manifest therefore that when Herat contained a population of a million and a half, as is assumed by so many contemporary writers, the present city could not have been only the citadel of this vast metropolis, the great mass of buildings lying along the slopes of the northern hills, where for a space of some 4 miles in length by 3 miles in breadth the surface of the plain, strewn on its surface with ruins of pottery and crumbling bricks, is also taken here and there by earthen mounds and tumuli, the details of platonic structures which at one time were the glory and wonder of the East. Of these structures and their origin we are enabled to the present day in a sufficiently plain state to bear witness to the grandeur and beauty of the old architecture of Herat. The mosque of the Mosalla, for instance, originally built in the 15th century, and restored or rather rebuilt in the end of the 16th century, and intended for the reception of the body of the Imam Riza who Shah Sultan Husseini wished to remove from Meshed to Herat, is, even at its present state of ruin and decay, one of the most imposing and elegant structures to be seen in Asia. The mosque, says General Foyat, "is completely covered with a mosaic of glazed bricks in varied and beautiful patterns, and the cupola is of varied dimensions. Several niches supported by pillars in brick and silver minarets that surround it may be said to be intact, for the upper part of them only is slightly injured." Scarcely inferior in beauty of design and execution, though of more moderate dimensions, is the tomb of the saint Abdullah Asad, in the same neighbourhood. This building, which was erected by Shah Bahlul Khan, the grandson of Timur, nearly 600 years ago, contains some exquisite specimens of sculpture in the style of the Chaghatay era. Adjoining the tomb also an immense wall, uninclosed, the splendour of princes of the house of Timur, and especially decorated with a royal building tastefully decorated by an Italian artist named Garaldi, who was in the service of Shah Bahlul Khan. The locality, which is further enhanced by gardens and running streams, is named *Guzal-gah*, and is a favourite resort of the Heratis. It is held in high veneration by all classes, and the funeral of Dost Mahomed Khan, who died in the month of the tomb of the saint. Two other royal princes named respectively *Dugh-i-Shah* and *Tahit-i-Safa*, are situated on the same rising ground somewhat further to the west. The buildings are now in ruin, but the view from the summit of the hill, which plan, lies on the terraced gardens formed on the slope of the mountain, is said to be very beautiful.

The population of Herat and the neighbourhood is of a very mixed character. The original inhabitants of Arian were a double of the Aryan family, and immediately cognate with the Persian race, but they were probably intermingled at a very early period with the Scyth and Medes, who seem to have been the founders of the Chahlu from Chahlu from the first days of history, and to whom must be ascribed—rather than to an invasion of Timur Partab—the blood introduced by the names of Timur and Timur—the peculiar blood of the Scyth and Medes, and the eastern provinces of Persia from their common origin in the west. Under the government of Herat, however, there is a very large number of tribes, ruled over by separate and semi-independent chiefs, and who are probably to different nationalities. The principal group of tribes is called the *Chakab-i-Jami*, or "hom azer," the constituent parts of which, however, are variously stated by different authorities both as to strength and nominal status. According to some authorities, by far the best general authority on Afghan questions, gives the original form tribes as the Taimans, the Hachaks, the Taimans, and Zais, Khanikoff, on the other hand, whose list was chronological, and who made his inquiries on the spot, divides the *Chakab-i-Jami* as the Eyvaks (100,000) number, the 14m hills (12,000), the Taimans (60,000), and the *Emur-koh* (10,000 to 12,000), while Pottinger substitutes the Soom-i-Herati of Bahlul Khan for the Eyvaks of Khanikoff, and the *Emur-koh* of the *Amir-i-Herati* to 80,000 Eyvaks. These tribes, all of them numbering to the north-east, the east, and the south-east of Herat, and number in the aggregate perhaps a million souls. Mirza Tayyar, who made special inquiries on the subject in 1876, found that the governors of Herat could use for fighting purposes, from the tribes and the allied Taimans of Herat 47,000 horse and 24,000 foot, but numbers have very much changed since Herat came under the government of Cabul in 1863, the recent policy being to leave the fighting force of the seat independent chiefs, and to substitute infantry regiments raised and paid by the central authority. At present there are perhaps ten such regiments, which can be supplemented by about 10,000 horse and 20,000 irregulars.

The trade of Herat is the subject of great fluctuation. From its central geographical position it must naturally be an emporium of commerce between Persia, Turkistan, Afghanistan, and India, while owing to the richness of the valley, which can supply its stock supplies for 150,000 men over and above the consumption of

the dried inhabitants, as well as to the mineral wealth of the adjoining mountains and the industrial activity of the city population, especially in regard to silk and woollen manufactures (the exports of Hérat being famous throughout the East), the country rapidly recovers from the effects of war, and its normal condition may be said to be that of prosperity and abundance.

In actual territory Hérat extends east and west from near the sources of the Helmand about 300 miles to the Persian frontier beyond Herat, and north and south from the Malay boundary, in about 36° lat., 200 miles to the northern limit of Russian. The inhabitants of the city of Hérat it are for the most part Shikhs, and in regard to language and habits, as well as religion, are Persian rather than Afghan. There are, however, both in the town and in the neighbouring villages a certain number of Afghan colonists, who have been settled there—the greatest part by Nadir Shikhs—during the last 150 years, as well as Hazarehs, Farsis, and Turms, with a fair sprinkling of Hindus and some forty families of Jews. The net revenue of the valley and its immediate dependencies in ordinary times is under £100,000 per annum, but the viceroy Yafar Mahmud Khan is supposed in the plenitude of his power, and when he had for a time brought a great part of Sindian under his sway, to have realized double that amount from the same province.

To give us any detail the fortunes of Hérat would be to write the modern history of the East, for there has hardly been a dynastic revolution, or a foreign invasion, or a great civil war in Central Asia since the time of the Prophet, in which Hérat has not played a conspicuous part and suffered accordingly. Under the 'Abbasids of Khoresm, the best rulers of Sistan, and the Samanids of Belukh, it furnished for some centuries in peace and progressive prosperity, but during the succeeding rule of the Ghaznavids, Kungs its metropolitan character was for a time obscured by the celebrity of the neighbouring capital of Ghor, and finally in the reign of Balban, Sultan of Malw about 1187 the city was entirely destroyed by an invasion of the Ghor, the predecessors, in 1200 as well in the reign of the modern Turcoman. Hérat gradually recovered under the enlightened Ghoriya kings, who not only ruled over the province, though they preferred to hold their court and their treasury in the mountains of Ghazni, so that at the time of Timur Khan its invasion expelled or even exterminated populations and with the few remains of Belukh, Malw, and Sindian, the united strength of the four states being estimated at three millions of inhabitants. But this Mongol invasion was most calamitous, forty persons, indeed, are stated to have alone survived the general massacre of 1212, and as the ruins of Belukh and Sindian overtook the city in the limits of Timur in 1398, when the local dynasty of Kart which had succeeded the Ghoris in eastern Khoresm was put an end to, it is astonishing to find that only in the 15th century Hérat was again flourishing and populous, and the favoured seat of the art and literature of the East. It was indeed under the patronage of the house of Timur that most of the noble buildings were erected, of which the remains still bear an abundant hint at Hérat, while all the great history it owes relative to Amir Timur is the *Book of the Kings*, the *Shah-nama*, the *Ma'athat* or *Sa'adat*, &c., data from the same place and the same age. Four times was Hérat visited by Turcomans and Uzbeks since the fall of the kingdom of the Ghoris, and the Timurid princes and the rise of the Afghan power, and it is here, in modern times claimed to anything like its old importance. Afghan tribes, who had originally dwelt far to the east, were first settled in Hérat by Nadir Shikhs, and since then have been incorporated by the government and formed the dominant element in the population. It will be needless to trace the revolutions and counter-revolutions which have followed each other in quick succession at Hérat and in the province, the first of the French invasion, the capture of the middle of the last century. Let it suffice to say that Hérat it has been throughout the seat of an Afghan government, sometimes in subordination to Kabul and sometimes independent. It was included for in 1819, when a strong disposition to recognize the suzerainty of Hérat which was evinced by the Shah Yusef Khan, but that in this, disapproving of the advance of Persia towards the Indus in front, strictly evoked the encroachment, and, indeed, by helping the Heratians, which the evacuation of the French in 1818, the British at length compelled the Shah in 1857 at the close of his war with Russia to sign a treaty recognizing the future independence of the place, and pledging Persia against any further interference with the Afghans. In 1860 Hérat, which for fifty years previously had been independent of Kabul, was incorporated by Dost Mahmud Khan in the Afghan monarchy, and such is the present condition of the principality, the last Governor Ayub Khan being the throne-holder, and deputy of Yusef Khan, which is engaged with the Government of India the famous treaty of Gandamak. (H. O. R.)

HERAULT, a department in the south of France, formed from parts of the old province of Languedoc, is bounded on the N.E. by Gard, N.W. by Arroyon and Tarn, and S by Aude and the Gulf of Lyons. It has an area of 2444 square miles, and is situated between 43° 10' and 44° N

lat., 2° 30' and 4° 10' E long. Its greatest length is 84 miles, and its greatest breadth 60. About a third of the department consists of moorland, heath, and common, a fourth of arable land, a sixth of vineyards, and an eighth of wood. The southern prolongation of the Cevennes mountains forms the north boundary of the department. The highest point is about 4260 feet above the sea level. The ridges form the watershed between the waters of the Atlantic and the Mediterranean, and from it there flow the Vidouille, Masson, Héaulm, Livron, and Orb. Of these the Héaulm, 80 miles long, is the chief, and gives name to the department. The Vidouille forms the boundary between the department and that of Gard. The high mountains of the north are partly barren, partly wooded. In the extensive plains of the centre the vine and olive flourish, and figs, mulberries, and other fruit-trees are to be met with nearly in all parts. Grain is chiefly produced in the south. The soil of the north is chalky clay, of the centre light gravel, and of the south a strong rich loam. The "garigues" are considerable portions of waste land, covered with heath and shrubs. St. Loup, Conques, and St. Thibéry, the first of which is 750 feet high, are extinct volcanic cones. The greater part of the south coast consists of a series of salt marshes, separated from the sea by a narrow strip of land. The marsh of Than, the largest, stretches from the mouth of the Héaulm, and communicates, through the marsh of Frontignan, with that of Manguon, on the eastern coast of the department. The Canal du Midi, after stretching about 30 miles into the department, terminates at Agde. From Agde the navigation is kept up through the marshes by the canals of Agde and Radelle to Arques Montes. The coast line of the department is 66 miles long. In the valleys and at the foot of the mountains the climate is delightfully mild. Fish abound in the salt marshes. The vegetable productions comprise aromatic and dyeing plants, the alex opals prevail in the forests. The mineral wealth of the department is considerable. Mines of lignite, coal, iron, copper, and lead are wrought. It produces magnificent blocks of marble, also alabaster, gypsum, granite, sandstone, pottery clay, alum, and the marshes supply Franco with salt. At Gabian there is a petroleum well. Wine and oil constitute the chief agricultural wealth of the department. The red wines of St. Georges, St. Didier, St. Christol, and the white wines of Frontignan and Lunel, are held in high estimation. Considerable quantities of wheat, oats, and potatoes are grown. There is a large amount of excellent pasturage, and horses and sheep are extensively reared. Mulberries, pomegranates, figs, raisins and other dried fruits, and olives are prepared for exportation. The chief manufactures are woollen and cotton cloth, silk, paper, gunpowder, soap, and chemical substances. The department has Montpellier for its capital, and is divided into the arrondissements of Montpellier, Béziers, Lodève, and St. Pons, with 36 cantons and 331 communes. The population was 429,878 in 1872, and 448,053 in 1876.

HERBARIUM, or **HERB. SECUR.**, a collection of plants so dried and preserved as fully to illustrate then several specific characters. Since the same plant, owing to peculiarities of climate, soil, and situation, degree of exposure to light, and other influences, may vary greatly according to the locality in which it occurs, it is only by gathering together for comparison and study a large series of examples of each species illustrative of the flora of different regions that the laws of vegetable morphology, and many more points of scientific interest, can be satisfactorily determined. Thus, from the herbarium may be acquired a knowledge of those details concerning the minute structure of individual plants which are of necessity omitted in works of systematic botany, as also of the relative taxonomic importance of the characters to be met with in large groups of forms.

Commencing with British herbaria, the collection of the Royal Herbarium at Kew, generally acknowledged to be at once the most extensive and the best preserved and most orderly in the world, comprises some 100,000 species, many of them represented by numerous specimens. It is arranged, for easy reference, in cases situate between the windows of the building containing it, the atmosphere of which is kept dry by means of hot-water pipes. In the intervening spaces are tables for the purpose of study, which is further facilitated by the presence in the same building of a large and valuable botanical library. Next in importance is the herbarium of the British Museum, which comprises assemblages of specimens gathered by numerous eminent botanists. The collection of Dillenius is deposited at Oxford, and that of the late Professor Harvey at Trinity College, Dublin. The original herbarium of Linnaeus is in the possession of the Linnæan Society of London. With the more important British herbaria are to be ranked also those of Cambridge and Edinburgh. The collections of Jussieu and St Hilaire are included in the large herbarium of the Jardin des Plantes at Paris, and in the same city is the extensive private collection of Dr Cosson. At Geneva are three large collections,—De Candolle's, containing the typical specimens of the *Prodomus*, Delessert's fine scious, and Boissier's Mediterranean and Oriental plants. The university of Göttingen has had bequeathed to it the largest collection (exceeding 40,000 specimens) ever made by a single individual,—that of the late Professor Gisebich. At the herbarium in Brussels are the specimens obtained by the traveller Martius, the majority of which formed the groundwork of his *Flora Brasiliensis*. Other national herbaria sufficiently extensive to subserve the requirements of the systematic botanist exist at Berlin, St Petersburg, Vienna, Leyden, Stockholm, Upsala, Copenhagen, and Florence. Of those in the United States of America, the chief, formed by Asa Gray, is the property of Harvard university; others are to be seen at Yale and Columbia colleges and at New York and Michigan universities. The herbarium at Melbourne, Australia, under Baron Müller, has attained large proportions, and that of the Botanical Garden of Calcutta is noteworthy as the repository of numerous specimens described by writers on Indian botany.

Specimens of flowering plants and vascular cryptogams are, at Kew, generally mounted on sheets of stout smooth paper, of uniform quality, and in most cases 17 inches long by 11 inches broad, the palms and then allies, however, and some ferns, require a size of 22 by 14 inches. The tough but flexible coarse grey paper (Gairman's *Receptum*), upon which on the Continent specimens are commonly fixed by gummed strips of the same, is less hygroscopic than ordinary cartridge paper, but has the disadvantage of affording harborage in the inequalities of its surface to a minute insect, *Atrypa pulsatilla*, L., which commits great havoc in damp specimens, and which, even if noticed, cannot be dislodged without difficulty. The majority of plant specimens are most suitably fastened on paper by a mixture of equal parts of gum tiagacanth and gum arabic made into a thick paste with water. Rigid leathery leaves are affixed by means of glue, or, if they present too smooth a surface, by stitching at their edges. Where, as in private herbaria, the specimens are not liable to be handled with great frequency, a stitch here and there round the stem, tied at the back of the sheet, or slips of paper passed over the stem through two slits in the sheet and attached with gum to its back, or simply strips of gummed paper laid across the stem, may be resorted to. A new adhesive substance, a kind of fish glue, has lately come into use for this purpose, and is highly spoken of. To preserve from insects, the plants, after mounting, are brushed over with

a liquid formed by the solution of 1 lb each of creosote, sublimate and carbolic acid in 1 gallon of methylated spirits. They are then laid out to dry on shelves made of a network of stout galvanized iron wire. After this is written, usually in the right hand corner of the sheet, or on a label there affixed, the designation of each species, the date and place of gathering, and the name of the collector. Information as to economical or medicinal properties may either be added thereto, or mentioned on the back of the sheet. It is especially important to attach to the name of the plant the initials or abbreviated name of the author by whom it was first described, e.g., the words *Ulex fastuosus* alone, might signify either of two distinct plants, the one described by Linnaeus, the other by Agardh. When the generic name has been altered, but the specific name has been retained, the name of the original describer of the plant is placed in brackets before the name of the later author. Thus the *Entromorpha Grevillei* of Thuret, having been renamed, has become *Ulex Grevillei* (Thur). Le Jolis. The value of specimens in private herbaria is greatly enhanced by briefly stating on the lower left-hand corner of the sheet the characters that distinguish it from the plants most nearly resembling it. Other particulars as to habit, local abundance, soil, and claim to be indigenous may be written on the back of the sheet, or on a slip of writing paper attached to its edge. It is convenient to place in a small envelope gummed to an upper corner of the sheet any flowers, seeds, or leaves needed for dissection or microscopical examination, especially where from the fraction of the specimen it is impossible to examine the leaves for ulcepsicles, and whose seed is apt to escape from ripe capsules and be lost. The addition of a careful dissection of a flower greatly increases the value of the specimen. To ensure that all shall lie evenly in the herbarium the plants should be made to occupy as far as possible alternately the right and left sides of their respective sheets. The species of each genus are then arranged either systematically or alphabetically in separate covers of stout, usually light brown paper, or, if the genus be large, in several covers with the name of the genus clearly indicated in the lower left hand corner of each, and opposite to the names or reference numbers of the species. Undetermined species are relegated to the end of the genus. Thus prepared, the specimens are placed on shelves, or movable trays, at intervals of about 6 inches, in an light cupboard, on the inner side of the door of which, as a special protection against insects, is suspended a muslin bag containing a piece of camphor.

The systematic arrangement varies in different herbaria. The works usually followed are,—for dicotyledons, De Candolle's *Prodomus*, and Endlicher's or Bonpland and Hooker's *Genera Plantarum*, for monocotyledons, Kaul's *Enumeratio*, for ferns, Hooker and Baker's *Synopsis Filicum*, for mosses, Muller's *Synopsis Muscorum Fructuosorum*, for algae, Kützinger's *Phykologia generalis*, for hepatics, Gotsche, Lindenborg, and Nees ab Esenbeck's *Synopsis Hepaticarum*, and for other groups of cryptogamic plants the treatises of various authors scattered through numerous scientific publications. In certain herbaria, as in those of Boissier and Delessert at Geneva, the authority of the *Prodomus* is accepted only in the absence of any family. For the members of large genera, e.g., *Papav* and *Ficus*, since the number of copypolition or very widely distributed species is comparatively few, a geographical grouping is found especially convenient by those who are constantly receiving parcels of plants from known foreign sources. The ordinary systematic arrangement possesses the great advantage, in the case of large genera, of readily

indicating the affinities of any particular specimen with the forms most nearly allied to it in type. In the United States the species in the genera, and the genera in the orders, are usually arranged alphabetically, and the orders serially, sometimes, however, the genera are placed alphabetically throughout without reference to the orders. The alphabetical arrangement, provided works on systematic botany are referred to for the identification of particular plants, possesses the advantage of permitting ready reference to any given species, and also of being independent of changes of classification, but in Europe it is rarely adopted, on account of the counterbalancing practical inconveniences it is considered to present. Instead of keeping a catalogue of the species contained in the herbarium, which, owing to the constant additions, would be almost impossible, such species are usually indexed off with a pencil in the systematic work which is followed in arranging them, so that by reference to this work it is as possible to see at a glance whether the specimen sought is in the herbarium, and what species are still wanted. The custom commonly prevalent in Continental, especially German, herbaria of placing the dried specimens loosely between sheets of paper is not always of uniform character is liable to lead to the admixture of nearly allied forms in intricate genera, such as *Rubus*, *Rosa*, *Lieracium*, *Salix*, &c., unless a label is attached to each specimen, a precaution not always observed in German and English herbaria. It is much followed for flowering plants, with the exception of palms, for which Martius's arrangement is preferred. At Geneva Dr Candolle's original herbarium is arranged in exact accordance with his *Prodromus*. In the other large herbaria in that city, the mounting and arrangement of the specimens are conducted much as in England, with the exception that smaller-sized sheets of paper are used for cryptogams.

Specimens intended for the herbarium should be collected when possible in dry weather, care being taken to select plants or portions of plants in sufficient number and of a size adequate to illustrate all the characteristic features of the species. When the root-stems and roots present any peculiarities, they should invariably be collected, but the roots should be dried separately in an oven at a moderate heat. Roots and fruits too bulky to be placed on the sheets of the herbarium may be conveniently arranged in glass-covered boxes contained in drawers. The best and most effective mode of drying specimens is learned only by experience, different species requiring special treatment, and even the same several peculiarities. The chief points to be attended to are to have a plentiful supply of botanical drying paper, so as to be able to use about six sheets for each specimen, to change the paper at intervals of six to twelve hours, and to use one leaf of flowers with another, and to increase the pressure applied only in proportion to the dryness of the specimen. To preserve the colour of flowers pigments of cotton wool, which prevent bruising, should be introduced between them, as also, if the stems are thick and succulent, as in *Digitaria*, between these and the corolla. Flowers dissected and gummed on the sheets will often retain the colour which it is impossible to preserve in a crowded inflorescence. Before placing in a series press, should they be very bulky, the dead or some other suitable weight should be laid upon the top of the pile of specimens, so as to keep up a continuous pressure. Succulent specimens, as many of the *Cruciferae*, and sedges and various other *Cyperaceae*, require to be killed by immersion in boiling water before being placed in drying paper, or, instead of becoming dry, they will grow between the sheets. When, as with some plants like *Persea*, the thick dead stems are liable to cause the leaves to wrinkle in drying by removing the pressure from them, small pieces of bibulous paper or cotton wool may be placed upon the leaves near their point of attachment to the stem. When a number of specimens have to be submitted to pressure, ventilation is secured by means of flannels corresponding in size to the drying paper, and composed of strips of wood or wire laid across each other so as to form a kind of network. Another mode of drying is to keep the specimens in a box of dry sand in a warm place for ten or twelve hours, and then immerse them in drying paper. A third method consists in placing the specimen within bibulous paper, and enclosing the whole between two plates of glass closely pressed and supported in a wooden frame. The zinc plates are then drawn close together by means of straps,

and suspended before a fire until the drying is effected. By the last two methods the colour of the flowers may be well preserved. When the leaves are finely divided, as in *Cornus*, much trouble will be experienced in lifting a half-dried specimen from one paper to another, but this plant may be placed in a sheet of thin blotting paper, and the sheet containing the plant, instead of being turned itself, can then be moved. Thin straw coloured paper, which is used for biscuit bags, may be conveniently employed by travellers unable to carry a quantity of bibulous paper. It offers the advantage of fitting closely to thick succulent specimens, and of drying. A light but strong variegated, to which pressure by means of straps can be applied, and a few quires of this paper, if the paper be changed night and morning, will be usually sufficient to dry all except very succulent plants. When the specimen is too large for one sheet, and it is necessary, in order to show its habit, &c., to dry the whole of it, it may be divided into two or three parts, and each be placed on a separate sheet of paper. Specimens may be judged to be dry when they no longer cause a cold sensation when applied to the cheek, or assume a rigidity not out of the usual stages of preparation.

Each class of flowers or cryptogams plants requires special treatment for the herbarium.

Mosses are usually mounted on tough smooth white cutting paper in the following manner. Growing specimens of good colour and not too far advanced in age are selected, and are cut into a jettable form from adhering foreign particles, either in the sea or a rocky pool. Some species rapidly change colour, and cause the decay of any others with which they come in contact. This is especially the case with the *Scapanus* and *Polytrichum*, and a few others, which should therefore be brought home in a separate vessel. In mounting, the specimen is floated out in a flat white dish containing water, so that foreign matter may be detached, and a piece of paper of suitable size and colour is placed over it, either by the fingers of the left hand or by a pincette. It is then pushed, in order to show the mode of branching, and is squeezed out as much as possible. The sheet of paper is then pressed upon a bone knitting needle, answers well for the coarse species, and a camel's hair pencil for the more delicate ones. The paper with the specimen is then carefully removed from the water by sliding it over the edge of the dish so as to avoid the water as much as possible. If during this process part of the filament together, the beauty of the specimen may be restored by dipping the edge into water, so as to float out the part and allow it to subside naturally on the paper. The paper, with the specimen attached, is then laid on bibulous paper for a few minutes to absorb as much as possible of the superfluous moisture. When freed from excess of water it is laid on a sheet of thick white blotting paper, and a piece of smooth washed cotton is placed upon it (unwashed cotton, on account of its "fanning," adheres to the wet wool). Another sheet of blotting paper is then laid over it, and a number of similar specimens being found into a pile, the whole is submitted to pressure, the paper being changed every hour or two at first. The pressure is increased, and the papers are changed less frequently as the specimens become dry, which usually takes place in thirty-six hours. Strong species, especially stems, or leaves, or leaflets, or flowers, contract so much in drying that without strong pressure the edges of the paper become puckered. Other species of a gelatinous nature, like *Desmouza*, and *Desmouza*, may be allowed to dry on the paper, but will need not be subjected to pressure, as they no longer present a gelatinous appearance. Large coarse algae, such, for instance, as the *Phaeococcus* and *Laminaria*, do not readily adhere to paper, and require soaking for some time in fresh water before being pressed. The less robust species, such as *Sphaerococcus* and *Sargassum*, which do not adhere well to paper, may be made to do so by brushing them over either with milk carefully skimmed, or with a liquid formed by placing tannin (2 or 3) and water (13 or 14) in a small bottle, and shaking the bottle. The whole is then pressed together, and when cold is kept in a stoppered bottle. For use, the moss is removed by means of a camel's hair pencil, and is then laid to the under side of the specimen, which is then laid neatly on paper. For the more delicate species, such as the *Confertissima* and *Desmouza*, it is an excellent plan to place a small fusing fragment, carefully fused, a whole in water, and then press the moss of the same of an ordinary microscopical slide, and allow it to dry. The plant can then be at any time examined under the microscope without injuring the mounted specimen. A few small specimens, which form a most beautiful group, as *Palmetta* or *Saxifraga*, may be placed in a vessel of water, where after a few days they float like a scum, the earthy matter settling down to the bottom, and may be removed by dipping a piece of blotting paper into them, and pressing it dry. *Oenothera* may be mounted by the same position on a silver coin placed on a piece of paper in a plate, and pouring in water until the edge of the coin is just covered. The algae by its own peculiar arrangement will soon form a green scum, perfectly free from dirt around the coin, which may then be removed.

monisms, A and B , then either these are reducible to one, which is the true quality, or they are not, when each is conditioned by the other and their position is no longer absolute. (5) All quantitative conceptions are reducible to one, which implies unity, and they are incompatible with multiplicity. (4) But these may be a plain shilly of "isms," about the mere conception of being can say us nothing as to "isms." This doctrine here developed is the first cardinal point of Herbert's system, and has obtained for it the name of "plurivale realism."

The contradictions he finds in the common sense conception of substance, or of "a thing as the seat of a distribution," will now become obvious. Let us take the simplest thing, say A , having its attributes, a, b, c . We are led to posit each of these because each is present in intuition. But in conceiving A we make, not a position, but less an A than a position. But only one attribute, say a , can remove the absolute position from its original source, as Herbart would say. What we ask, What is the one position? We no longer tell the possessor of a, b, c or in other words, then sent on substance. But if so, then A , as a real, being simple, must a , similarly it must b , and so on. Now this would be possible if a, b, c were but "contingent aspects" of A , as $e, g, 2^1$, $WdA, 4-3-1$ two contingent aspects of B . Still, of course, is not the case, and so we have to multiply contingent aspects in this way thus but, for a we must say A is a , is not a , b is not b , c is not c . Then must then, according to the method of relations, be several A s. For a let us assume $A_1 + A_2 + A_3$, for b , $A_1 + A_2 + A_3$, and so on for the rest. But now what relation can there be among these several A s, which will restore to us the unity of our original A or substance? There is but one, we must assume that the first A of these is identical with the rest, as the center is the same point in every radius. By way of concrete illustration Herbart illustrates "the common observation that the properties of things exist only under certain conditions, we have really a series of facts, but each is nothing without light, and nothing without eyes. They would, but only in a vibrating medium, and for healthy eyes. Color and tone present the appearance of substance, but on looking closely we find that each is really a series of vibrations, which presuppose a communion among several." The result then is briefly thus—In place of the one absolute position, which in some unthinkable way the common understanding substitutes for the absolute positions of the attributes, we have really a series of two or more positions for each attribute, every sense, however, beginning with the sense (as it were, central) led (hence the unity of substance in a given sense) to the fact that each is being conditioned by different A s (hence the plurality and distance of attributes in intuition) which then is the appearance of substance. Therefore, there is always a plurality of reals, no such conclusion to substance as attribute or condition can be situated at all. Substantially is impossible without causality, and to this is its true qualitative we now turn.

The common sense conception of change involves at bottom the same contradiction of opposing qualities in one real. The same A that was a, b, c becomes a, b, d , and thus, which expects one change upon us, proves on reflection unthinkable. The mere physical supplementing is also fundamentally as before. Since a depended on a series of reals $A_1 + A_2 + A_3$ in communion with A , and d may be said similarly to depend on a series $A_1 + A_2 + A_4$, then the change from a to d means, not that the central A has changed, but that there is now a new communion with A_4 , $4c$, and no longer in communion with A_3 , $3c$.

But to think a number of reals "in communion" (*Zusammenhang*) will not suffice as an explanation of phenomena, something or other must happen when they are in communion, what is it? The answer to this question is the second large point of Herbart's theoretical philosophy. What is actually happens is as distinct from all that seems to happen, when two reals A and B are together in the qualities they tend to differ in quality, they tend to disturb each other to the extent of that difference, at the same time that each preserves itself intact by reacting, as it were, the other's disturbance. And so by coming together in communion, the "self preserving actions" of A will vary accordingly, A remaining the same through all, just as, by way of illustration, hydrogen remains the same in water and in ammonia, or as the same line may be now a normal and now a tangent. But as the same line may be now a normal and now a tangent, so the same A may be now a normal and now a tangent of the reals $A_1 + A_2$, we must substitute for these symbols others, which, though only "contingent aspects" of A and B , e, g , representing their relations, not themselves, yet like smaller devices, mathematicians enable thought to advance. Thus we may put $A = \alpha + \beta - \gamma$, $B = m + n + \gamma$, γ then represents the character of the self-preservation in this case, and $\alpha + \beta + m + n$ represents all that could be observed by a spectator in the relation of A to B , but was himself involved in the relations of A to B , and such is exactly our position.

Having thus done what really is and what actually happens, our philosopher proceeds next to express symbolically the objective semblance (*der objektive Schein*) that results from these. But if this construction is to be truly objective, α, β , valid for all intelli-

gences, ontology must furnish us with a clue. This we have in the forms of Space, Time, and Motion which are involved whenever we think the reals as being in, or coming into, connexion, and the appearance of these forms then cannot be merely the products of our psychological mechanism, though they are, but they are also in accordance with these. Moreover, let us call them "intelligible," as being valid for all who comprehend the real and actual by thought, although no such forms are produced by the intellect and actuality solves. The elementary spatial relation Herbart conceives to be "the contiguity (*Aneinander*) of two points," so that every "pure and independent line" is discrete. But an investigation of dependent outlines which we often unconsciously force us to adopt, the contradictory action of mutually overlapping, e, g , divisible points, or in other words, the conception of "Continuity." But the contradiction we cannot eliminate by the method of relations, because it does not involve anything real, and in fact is a necessary outcome of an "intelligible" form, the fiction of continuity is valid for the "objective semblance," and no more to be discarded than α, β, γ . By its help we are enabled to comprehend just actually happens among reals to produce the appearance of nature. When two or more reals are together, each disturbance and self preservation will (in general) be reciprocal, e, g , of less intensity than when only one real is together. But "objective semblance" corresponds with reality, the spatial or external relations of the reals in this case must, therefore, tally with their actual or actual states. Had the actual preservation been perfect, the coincidence in space would have been complete, and the group of reals would have been monoidal, or had the several reals been equally contiguous, e, g , without connexion, then, as nothing could actually have happened, the actual situation of the reals, as it were, would be the same as the manifest attractive and repulsive forces, each action corresponding to the tendency of the self preservation to become perfect, repulsion the actual situation of the "Motion, even more evidently than space, implies the contradictory conception of continuity, and therefore, to be a real products, though valid as an intelligible form and necessary to the comprehension of the objective semblance. For that of the reals is necessary to the comprehension of the reals as entering into connexions. This we can only do by conceiving them as originally moving through intelligible space in rectilinear paths and with uniform velocities. For each motion no cause need be assumed, but each motion, in fact, is no more a state of the moving real than rest is, both also being but relations, with which, therefore, the real has no concern. The changes in this motion, however, for which we must assume a cause, and sequence a cause, are the actual occurrences of the self preservation that actually come when reals meet. Further, by means of such motion these actual occurrences, which are in themselves timeless, full for an observer in a definite time—a time which becomes continuous through the partial coincidence of events.

But in all this it has been assumed that we are spectators of the objective semblance, it remains to make good this assumption, or, in other words, to show the possibility of knowledge, this is the problem of which Herbart treats. Epistemology, and forms the transition from metaphysics to psychology. Here, again, a contradictory conception blocks the way, that, viz., of the ego as the identity of knowing and being, and as such, the standpoint of idealism. The contradiction becomes more evident when the ego is defined to be a subject (and so a real) that is its own object. As real and not merely formal, this conception of the ego is amenable to the method of relations. The solution this method affords is, however, that there are several objects which mutually modify each other, and so constitute that ego we take for the presented real. But to explain this modification is the business of psychology, it is enough now to see that the subject like all reals is necessarily unknown, and that, therefore, the idealist's theory of knowledge is unsound. But though the simple quality of the subject or soul is beyond knowledge, we know what actually happens, and we know that other's reals, for its self preservation, then so what we call sensations. And these sensations are the sole material of our knowledge; but they are not given to us as a chaos but in definite groups and several others, so we come to know the real as it is, though they themselves unknown, our sensations compel us to posit absolutely.

In his *Psychology* Herbart rejects altogether the doctrine of mental qualities as so refuted by his metaphysics, and tries to show that all psychical phenomena whatever result from the action and interaction of elementary ideas or presentations (*Vorstellungen*). The soul bears one and simple, its representative self preservation or primary presentations must be simple too, and its several presentations must become united together. And this they can do at once and completely when, as in the case, for example, with the several attributes of an object, they are not of opposite quality. But otherwise that a chaos is conflict in which the opposed presentations combat themselves like forces and mutually suppress or obscure each other. The act of presentation (*Vorstellung*) them

¹ Hence Herbart gives the name Synecismology to this branch of metaphysics, instead of the usual one, Cosmology.

becomes partly transformed into an effort, and its product, the vice, becomes in the same proportion less and less intense till a position of equilibrium is reached, and then at length the unaided mind ceases. We have thus a static, and a mechanics of mind which investigate respectively the conditions of equilibrium and of movement among presentations. In the static two magnitudes have to be determined—(1) the amount of the suppression or inhibition (*Demmungskraft*), and (2) the ratio in which this is shared among the opposing presentations. The first must obviously be as small as possible, thus for two totally opposed excitations a and b , of which a is the greater, the *inhibition* $a - b$. For a given degree of opposition this burden will be shared between the competing presentations in the inverse ratio of their strength. When its command after inhibition = 0, a presentation is said to be on the threshold of consciousness, for on a small diminution of the inhibition the "effort" will become actual presentation in the same proportion. Such total exclusion from consciousness is, however, manifestly impossible with only two presentations, though with three or a greater number the residual value of one may even be negative. The first and simplest law in psychology, mechanism, is thus the "sinking" of inhibited presentations. As the presentations yield to the pressure, the psychic stimulus diminishes, so that the velocity of sinking decreases, i.e., we have the equation, $(S - e) dt = ds$, where S is the total *inhibition*, and e the intensity actually inhibited after the time t . Hence $t = \log \frac{S}{S - e}$, and $\sigma = S(1 - e^{-t})$.

From this law it follows, for example, that equilibrium is never quite obtained for those presentations which continue above the threshold of consciousness, while the rest which are not so continue to be very speedily driven beyond the threshold. More important is the law according to which a presentation freed from inhibition and rising away into consciousness tends to raise the other presentations with which it is combined. Suppose one presentation is represented by the total x , and p , then the amount of p 's "help" to x is $\frac{1}{p}$, the portion of which appropriated by x is given by the ratio $p = x$, and thus the mutual help is $\frac{1}{p}$.

But after a time t , when a portion of p represented by w has been actually brought into consciousness, the help afforded in the next instant will be found by the equation

$$\frac{1}{p} \frac{dw}{dt} = w - dw,$$

from which by integration we have the value of w ,

$$w = p(1 - e^{-\frac{t}{p}}).$$

So that if there are several x 's connected with p by similar and similar parts, there will be a definite "zero" order in which they will be raised by p , and on this fact Herbart rests all the phenomena of the so-called faculty of memory, the development of spiritual and temporal forms, and much besides. Emotions and volitions, he holds, are not directly self-presentations of the soul, as our presentations are, but variable states of such presentations resulting from their interaction when above the threshold of consciousness. Thus when some presentations tend to force a presentation into conscious awareness, and others at the same time tend to divert it, that presentation is the seat of painful feeling. On the other hand, if interference is favoured by all, pleasant ideas. Denies as presentations stringing into consciousness against hindrance, and when accompanied by the suppression of success, become volitions. Transcendental freedom of will in Kant's sense is an impossibility. Self-consciousness is the result of an interaction essentially the same in kind as that which takes place when a comparatively simple presentation finds the field of consciousness occupied by a long formed and well-consolidated "mass" of presentations— a, e, p , our's but e as given, the theatre, &c., which promptly inhibit the volition we want when it is incongruent, and invite it to themselves if not. What we call self is, above all, such a central mass, and Herbart seeks to show with great ingenuity and detail how it develops in the first place by the body, then by the sort of ideas and desires, and finally by that first personified self which collects the past and resolves on "completion" are variable, the concrete presentation of self is never twice the same. And, therefore, finding on reflection any year which occupies it, and so reach the speculative notion of the pure Ego.

Efficiency elaborates the "alloy" involved in the expression of taste called forth by the relations of object which acquire for them the attribution of beauty or the reverse. The beautiful (*schön*) is

1. Thus, taking the case above supposed, the share of the *inhibition* falling to the smaller presentation b is the fourth form of the proportion $a + b : a :: b : \frac{ab}{a+b}$, and so b 's remainder is $b - \frac{ab}{a+b} = \frac{b^2}{a+b}$, which only = 0 when $a = \infty$.

to be carefully distinguished from the allied conceptions of the useful and the pleasant, which vary with time, place, and person, whereas beauty is predicated absolutely and involuntarily by all who have attained the right standpoint. Ethics, which is but one branch of aesthetics, although the chief, deals with such relations among volitions (*Willensbestrebungen*) as thus unconditionally place as or displace. These relations Herbart finds to be reducible to five, which do not admit of further simplification, and corresponding to them are as many moral ideas (*Affektideen*), viz.—(1) *Internal Freedom*, the underlying relation being that of the individual's will to his judgment of it; (2) *Perfection*, the relation being that of his several volitions to each other as respects intensity, variety, and concentration; (3) *Democracy*, the relation being that between his own will and the thought of another's; (4) *Right*, in case of actual conflict with another; and (5) *Utilitarianism*, or *Equity*, for intended good or evil done. The basis is, first of all, a system of rewards and punishments, a system of ultimate sanction, a system of culture, and a "moralized society" corresponding to the ideas of law, equity, benevolence, perfection, and internal freedom respectively, beside which are five elements of a number of individuals. Virtue is the perfect conformity of the will with the moral ideas, of this the single virtues are but special expressions. The conception of duty arises from the evidence of hindrance to the attainment of virtue. A general scheme of principles of conduct is possible, but the subsumption of special cases under this must remain matter of fact. The application of these to things as they are with a view to the realization of the moral ideas is moral technology (*Eugenik*), of which the chief divisions are Paedology and Politics.

In *Theology* Herbart laid the argument down from which it is valid for divine reality as for human, and to justify the latter in a super-sensible realm, concerning which he held no religious is not attainable nor on practical grounds denied.

Among the post-Kantian philosophers Herbart doubtless ranks next to Hegel in importance, and this without taking into account his very great contributions to the science of logic. His explicit aspect of things as the "exact philosophy," and the form which expresses their specific excellence and the character of the chief influence he has exerted upon succeeding thinkers of his own and other schools. His criticism is even more than his constructive, indeed for evolution and perfection of thought he is quite on a level with Hume and Kant. His merits in this respect, however, can only be appreciated by the study of his works at first hand. But we are most of all indebted to Herbart for his continuous advance psychology has been enabled to make, thanks to his first full treatment of it, albeit as yet but few among the many who have appreciated and improved his material have ventured to adopt his metaphysical and mathematical foundations. (J. W. S.)

HERBELOT, BARTHÉLEMY D' (1625–1695), Orientalist, was born December 4, 1625, at Paris. As soon as he had completed the ordinary course in classics and philosophy at the university of his native city, he devoted himself to the study of the Oriental languages, and went to Italy to perfect himself in them by converse with the Orientalists who frequented its seaports. There he made the acquaintance of his fellow-savants Lucas Holstenius and Leo Allatius, and attracted the favourable notice of the cardinals Gualandi and Barberini. On his return to France after a year's sojourn, he was received into the house of Fouquet, superintendent of finance, who gave him a pension of 1500 livres. Losing this on the disgrace of Fouquet in 1661, he was appointed secretary and interpreter of Eastern languages to the king. A few years later he again visited Italy, when the grand duke Ferdinand II. of Tuscany presented him with a large number of valuable Oriental MSS., and tried to attach him to his court. Hebertot, however, was recalled to France by Colbert, and received from the king a pension equal to the one he had lost. In 1692 he succeeded D'Arvigne in the chair of Syriac, in the Collège de France. He died at Paris, December 8, 1695. His great work is the *Bibliothèque Orientale, ou catalogue raisonné contenant tout ce qui fait connaître les peuples de l'Orient*, which occupied him nearly all his life, and was published in 1697 by Galland. It is based on the immense Arabic dictionary of Hagi Khalfa, of which indeed it is largely an abridged translation, but it also contains the substance of a vast number of other Arabic and Turkish compilations and manuscripts. With all his learning, the author seems to have been deficient in critical

signity, and there is consequently a want of minute accuracy in many of its details, and of harmony between its various parts. It is, however, even yet the one available source for much information to others than Oriental scholars, and as such it retains its importance.

The *Bibliothèque* has been reprinted at Macclesfield (fol 1776), and at the Hague (4 vols 4to, 1777-89). The latter edition is enriched with the contributions of Schultens, Runko, and others. Herbert's other works, none of which have been published, consist of an *Oriental Anthology*, and an *Arabic, Persian, Turkish, and Latin Dictionary*.

HERBERT, GEORGE (1593-1633), one of the best of English religious poets, was born near the town of Montgomery on the 3d of April 1593. He was a brother of Lord Herbert of Chesham, noticed below. Educated privately till the age of twelve, he was then sent to Westminster School, and in 1608 he became a student at Trinity College, Cambridge, where he was made B.A. in 1611, M.A. and major fellow of the college in 1615, and orator to the university in 1619. In his capacity as orator he was several times brought into contact with King James. About the same time also he appeared as the champion of Anglicanism against Andrew Melville, the famous Scotch Presbyterian. He numbered among his friends Dr Donne, Sir Henry Wotton, Isaac Walton, Bishop Andrews, and Francis Bacon, who consulted Herbert about several of his works, and dedicated to him his translation of the Psalms. During his youth he was a courtier, dancing attendance on King James, and "enjoying his genteel humour for clothes", and the king rewarded his attentions by the gift of a sash worth £120 a year. The death of his patrons the duke of Richmond, the marquis of Hamilton, and King James, approaching ill-health, and the influence of his mother finally induced him, not without a struggle, to take holy orders. In July 1626 he was appointed prebendary of Leyton Ecclesia, in the county of Huntingdon. Shortly before his induction (1630) to the parsonage of Bemerton, near Salisbury, he married Miss Jane Danvers after three days' acquaintance. Mr Danvers had been set on the marriage for a long time, and had often spoken of his daughter Jane to Herbert, and "so much commended Mr Herbert to her, that Jane became so much a Platonic as to fall in love with Mr Herbert unseen." The story of the poet's life at Bemerton, as told by Walton, is one of the most exquisite pictures in literary biography. He devoted much time to explaining the meaning of the various parts of the Prayer-Book, and held services twice every day, at which many of the parishioners attended, and some "let their plough rest when Mr Herbert's sermons bell rung to prayer, that they might also offer their devotions to God with him." Next to Christianity itself he loved the English Church. He was passionately fond of music, and usually went twice a week to attend the cathedral service at Salisbury. Walton illustrates Herbert's kindness to the poor by many touching anecdotes. He had not been three years in Bemerton when he succumbed to ill health. He died in 1633.

Herbert's works are—*The Temple* (1633), a few miscellaneous poems, a collection of sermons entitled *Jesus Preached* (1640), and *The Country Parson*, which did not appear till 1652. *The Temple* is a collection of religious poems marked by unity of sentiment and inspiration. The chief faults of the book are obscurity, verbal conceits, and a forced ingenuity which shows itself in grotesque puns, odd metaphors, and occasional want of taste. In spite of these drawbacks, the quaint beauty of Herbert's style and his genuine poetical feeling give *The Temple* a high place in literature. The following poems are the gems of the collection:—"The Church-Porch," "The Agony," "Sin," "Sunday," "Virtue," "Man," "The British Church," "The Gnat," "The Collar," "The Pulley," "The Flower," "Anemone," and "The Elm." The finest of all his poems on "Man," which is Miltonic in its sublimity of conception, and shows how poets, in their loftiest moods, often anticipate the discoveries of science and the most far-reaching speculations of philosophy. Herbert and Keble are the poets of Anglican

theology. No book is fuller of devotion to the Church of England than *The Temple*. No poem in our language exhibits more of the spirit of true Christianity. Every page is marked by transparent sincerity, and reflects the beautiful character of "holy George Herbert."

Among recent editions of Herbert's works the following may be mentioned:—*Herbert in Prose and Verse*, with life by Isaac W. Allen, and notes by S. T. Coleridge, 1846; Gilliland's edition, in his "Library of the British Poets," 1858; Walgrave's edition, 1854; Professor Nichol's edition, 1868, and the Aldine edition by the Rev Dr A. B. Grosart. For further information consult Walton's *Life*, and England's *Antiquary*, by George MacDonald, 1871.

HERBERT, HENRY WILLIAM (1807-1858), novelist and writer on sports, son of the Hon and Rev William Herbert, dean of Manchester, a son of the first earl of Carnarvon, was born in London, April 7, 1807. He was educated at Eton and at Caius College, Cambridge, where he graduated M.A. in 1828. Having become involved in debt he emigrated to America, and from 1831 to 1839 was teacher of Greek in a private school in New York. In 1833 he commenced the *American Monthly Magazine*, which he edited till 1835. In 1834 he published his first novel, *The Brothers*, a *Tale of the Fionde*, which was followed by a number of others, all of them obtaining a certain degree of popularity. He was also successful in a series of historical studies, such as *The Cavaliers of England*, *The Knights of England*, *France and Scotland*, *The Chevaliers of France*, and *The Captains of the Old World*, and wrote numerous contributions to magazines, but he is best known for his works on sports, published by him under the pseudonym of Frank Forester. These include *The Field Sports of the United States and British Provinces* (1849), *Frank Forester and his Friends* (1849), *The Fish and Fishing of the United States* (1850), *The Young Sportsman's Complete Manual*, and *The Horse and Horsemanship in the United States and British Provinces of North America* (1855). Herbert was a man of varied accomplishments, but of somewhat dissipated habits. He died by his own hand at New York, May 17, 1858.

HERBERT, SIR THOMAS (1606-1682), traveller and author, was born at York in 1606. Several of his ancestors were aldermen and merchants in that city, and they could trace their connexion with the great Herbert family represented by the earl of Pembroke. His grandfather, Alderman Herbert, who died in 1614, left him real estate of considerable value. He went to Oxford in 1621, and became a commoner of Jesus College, but afterwards removed to Cambridge at the invitation of his mother's brother, Dr Ambrose Aylmer. Having gone to London, he was introduced to the earl of Pembroke, through whose influence he obtained an appointment in the suite of Sir Dodmore Cotton, who was about to leave as ambassador for Persia in company with Sir Robert Shirley. Sailing in March 1627, they visited the Cape, Madagascar, Goa, and Surat, having landed at Gombroon, they travelled inland to Achaioff, and thence to Casheen, where both the chiefs of the expedition died. Herbert reached England again in 1629, and in 1630, to his great disappointment, he paid the earl of Pembroke died suddenly. After this he travelled on the Continent for more than a year. From his return in 1631 till about two years after his marriage in 1632 he retained his ambition for court favour, but failing in this he retired, probably to his estate of Trintin in Monmouthshire, till the outbreak of the civil war, when he sided with the parliament. In 1646 he was appointed to attend the king with his other servants. Becoming a devoted royalist, he continued with his majesty during the last two eventful years of his life, and at the Restoration he was rewarded with the title of baronet (1660). He resided at Westminster till the great plague, when he returned to York and bought Petegate House, where he died on the 1st March 1682.

of Buckingham's ill-fated expedition in 1627. *The Life and Reign of King Henry VIII* (1649), in pathy English, is called by Walpole "a masterpiece of historic biography," but is in proportion "and is digested into annals." It abounds in picturesque but merely as counts of sieges and sieges, and is at home and abroad, the sketch of the Reformation history is so dispassionate, as to suggest a lack of keen sympathy with either party. Henry's character is very lamentably judged. *The Life of Herbert by Himself* (first published by Horace Walpole in 1764) gives a very accurate and interesting account of his only life down to the return from his embassy, dwelling mainly, with something of an old man's vanity and a famous man's vanity, on the romantic and chivalrous incidents in his career. Herbert's poetry, Latin and English, is small and unimportant.

There are sketches of Herbert in Leland's *Historical Collections*, Lechlair's *Geschichte des Englischen Dramas*, and elsewhere, but the only valuable work, in M. Charles de Ruvigny's *Lord Herbert de Cherbourg*, in *Pic et de la Normandie* (Paris, 1874).

HERCULANEUM. The ruins of the buried city of Herculaneum are situated about two-thirds of a mile from the Portici station of the railway from Naples to Pompeii. They are less frequently visited than the ruins of the latter city, not only because they are smaller in extent and of less obvious interest, but also because they are more difficult of access. The history of their discovery and exploration, and the artistic and literary relics which they have yielded, are worthy, however, of particular notice. The small part of the city which has been restored to the light of day in the spot called *Gli scavi nuovi* (the new excavations) was discovered in the present century. But the more important works were excavated in the last century, and of the buildings then explored at a great depth, by means of tunnels, none are visible except the theatre, the orchestra of which lies 85 feet below the surface of the soil.

The brief notices of the classical writers inform us that Herculaneum¹ was a small city of Campania between Naples and Pompeii, that it was situated between two streams at the foot of Vesuvius on a hill overlooking the sea, and that its harbour was at all seasons safe. With regard to its earlier history nothing is known. The account given by Dionysius repeats a tradition which was most natural for a city bearing the name of Hercules. Strabo follows up the topographical data with a few brief historical statements—"Ορεινὸν ἔκταν καὶ κατὰ τὴν ἐξέχῃσι περικυκλωμένην τρυφήν καὶ πλεονασμῷ, κατὰ τὰς ἀναστάσεις. But leaving the questions suggested by those names, such as that of the domination of the Etruscans in Campania,² as well as the other questions recently discussed in regard to the origin of Pompeii, which might have an intimate relation with our subject, it is sufficient here to say that the first historical record about Herculaneum has been handed down by Livy (viii. 26), where he relates in what manner the city fell under the power of Rome during the Samnite wars. It remained faithful to Rome for a long time, but it joined the Italian allies in the Social War. Having submitted anew in June of the year 666 (88 B.C.), it appears to have been less severely treated than Pompeii, and to have escaped the imposition of a colony of Sulla's veterans, although Zumpt has suspected the contrary.

¹ A fragment of L. Silienus calls it "Opulenti tumulo in excollo loco prope mare, parvi montis, inter duas flumines, infra Vesuvium collocatum" (lib. vi., fragment 53, Peters). Of one of these rivers the historian again makes notice in the passage where he probably is related the capture of Herculaneum by Minutius Magnus and Titus (Velleius Paterculus, ii. 16). Further topographical details are supplied by Strabo, who, after speaking about Naples, continues—"Ἐκπύρην δὲ ἀποκαλεῖται τὴν ἡμετέραν ἀνακτορὰν αὐτὴ τῆς πόλεως ἀπὸ τῆς κατὰ τὴν ἀνακτορᾶν ἀπὸ τῆς ἀνακτορᾶς ἐκείνης τῆς πόλεως." Dionysius of Halicarnassus relates that Herculius, in the place where he stopped with his fleet on the return voyage from Ilium, founded a little city (πάλαιον), to which gave his own name, and he adds that this city was in his time inhabited by the Romans, and that, situated between Neapolis and Pompeii, it had *ἀνέκτατα ἐν πύρρῳ καὶ βελούρῳ* (i. 44).

² Discussed by Niebuhr, *Hist. of Rome*, vol. i. p. 76, and by Mommsen, *Die Römische Geschichte*, 1860, p. 814.

(*Comm. Epigr.*, i. 259). It afterwards became a municipium, and enjoyed great prosperity towards the close of the republic and in the earlier times of the empire, since many noble families of Rome selected this pleasant spot for the construction of splendid villas, one of which indeed belonged to the imperial house (Seneca, *De Ira*, iii.). By means of the Via Campana it had easy communication north-westward with Neapolis, Puteoli, and Capua, and thence by the Via Appia with Rome, and southwards with Pompeii and Nuceria, and thence with Lucania and the Bruttii. In the year 63 A.D. it suffered terribly from the earthquake which, according to Seneca, "Campaniam nunquam secutum hujus mali, indomem tamen, et totius defunctam metu magna strage vastavit. Nam et Herculaneum oppidi parvi, ut diuque stant etiam quae selecta sunt" (*Nat. Quæst.*, vi. 1). Hardly had Herculaneum completed the restoration of some of its principal buildings (see Mommsen, *I. A.*, n. 2384, *Catalogo del Museo Nazionale di Napoli*, n. 1161) when it fell beneath the great eruption of the year 79, described by Pliny the younger (*Ep.* vi. 16, 20), in which Pompeii also was destroyed with other flourishing cities of Campania. According to the commonest account, on the 23d August of that year Pliny the elder, who had command of the Roman fleet at Misenum, set out to render assistance to the soldiers stationed at Stabiae, near Herculaneum, as there was no escape except by sea, but the little harbour having been on a sudden filled up so as to be inaccessible, he was obliged to abandon to their fate those people of Herculaneum and Stabiae who had managed to flee from their houses, overwhelmed in a moment by the material poured forth by Vesuvius. But the text of Pliny the younger, where this account is given, has been subjected to various interpretations, and from the comparison of other classical testimonies and the study of the excavations it has been concluded that it is impossible to determine the date of the catastrophe, though there are satisfactory arguments to justify the statement that the event took place in the autumn. The opinion that immediately after the first outbreak of Vesuvius a torrent of lava was ejected over Herculaneum was refuted by the scholars of the last century, and their refutation has been recently confirmed by Deulà (*Le Dams du Vesuvius*, p. 240 sq.). And if the last reconstructions of the passage quoted from Pliny are to be accepted, Stabiae is not the name of the harbour described by Deulà (ib., p. 122, 247), but the name of a lady who had implored succour, the wife of Cæsus Bassus, or rather Tascus (cf. Pliny, ed. Keil, Leipzig, 1870, Aulus Persius, ed. Jahn, *Sat.* vi.). The shore, moreover, according to the new and accurate studies of the engineer Michele Ruggieri, director of the excavations, was not altered by the causes advanced by Deulà (p. 125), but by a simpler event. "It is certain," he says (*Pompeii e le Rovine Sotterrate dal Vesuvio l'anno 79*, Naples, 1870, p. 21 sq.), "that the districts between the south and west, and those between the south and east, were overwhelmed in two quite different modes. From Torre Annunziata (which is believed to be the site of the ancient Oplontis) to San Giovanni a Teduccio, for a distance of about 9 miles, there flowed a muddy eruption which in Herculaneum and the neighbouring places, where it was most abundant, raised the level of the country more than 65 feet. The matter transported consisted of soil of various kinds, sand, ashes, fragments of lava, puzolana, and whitish pumice, enclosing grains of uncoloured lime, similar in every respect to those of Pompeii. In the part of Herculaneum already excavated, the corridors in the upper portions of the theatre are compactly filled, up to the head of the arches, with puzolana and pumice transformed into tuff (which proves that the formation of this stone may take place in a comparatively short time). Tuff is also

are in themselves sufficient to show that the library belonged to a person whose principal study was the Epicurean philosophy. But of the great mass of this school only a few works have been found. Of his treatise *Περὶ δόξης*, divided into 67 books, it is known that there were three copies in the library (*Coll. alt.*, vi).

Quite recently Professor Compagnotti, studying the first fasciculus of volume xi. of the same new collection, recognized most important fragments of the *Stoicæ de Pyrrone*, and these he published in 1879 in Nos. ix. and xi. of the *Revue des Études classiques*, Turin. Even the other authors above mentioned are but poorly represented, with the exception of Philodemus, of whom 95 different treatises have been recognized. But all these philosophic discussions, belonging for the most part to an author less than secondary among the Epicureans, fall short of the high expectations excited by the first discovery of the library. Among the many volumes unrolled only a few are of historical importance,—that edited by Bucheler, which treats of the philosophers of the academy (*Acad. phil. stoicæ Herod.*, Göttingen, 1860), and that edited by Compagnotti, which deals with the Stoics (*"Papiri erodiani inediti," in Rivista di Fil. ed. let. class. anno iii.*, fasc. x. xii.). To appreciate the value of the volumes unrolled but not yet published (for 146 vols. were only copied and not printed), the student must await the appearance of Compagnotti's

paper, "Relazione sui papiri erodiani," read in the Reale Accad. dei Lincei, which will appear in the "Proceedings" of the academy for 1879. Contributions of some value have been made to the study of Heracleum fragments by Spongel (*"Die Herakl. Rollen," in Philologus*, 1863, suppl. vol.), and Compagnotti (*Herakl. Studien*, Leipzig, 1866-68, cf. *Zeitschr. f. klass. Philol.*, 1867-1872). There are in the library some volumes written in Latin, which, according to Boet (*Notæ sur les manuscrits trouvés à Herculaneum*, Amsterdam, 1840), were found tied up in a bundle upon the shelves we know 18, but they are all so damaged that hardly any of them can be deciphered. One with verses relating to the battle of Actium is believed to belong to a poem of Valerius Flaccus. The preponderance of the works of Philodemus led some people to believe that this had been the library of that philosopher. But quite recently Professor Compagnotti has come to the conclusion that the library was collected by Lucius Piso Cessionius (see *Papiri e in Regius Sottorata dal Vesuvio*, Naples, 1879, p. 150 sq.). A new support to the theory of Professor Compagnotti is furnished by the cuneiform fragment edited by De Petra (*ib.*, p. 261 sq.); but Dr. Mai takes up a counter position,—he is the first to do so,—and shows that the fragment must have another interpretation (*Phil. Inst. di Corr. Arch.*, 1880). Professor De Petra has also published the official notices upon the antiquities unearthed in the sumptuous villa, giving the plan executed by Weber and recovered by chance by the director of excavations, Michele Ruggiero. This plan, which is here reproduced from De Petra's monograph,¹ is the only satisfactory document for the topography of Heracleum, for the plan of the theatre published in the *Bullettino archeologico napoletano* (Naples, 1881, i. p. 63, tab. m.) was executed in 1747, when the excavations were not completed. And even for the history of the finds made in the *Villa Subura* there is no necessity for further studies makes itself felt, since there is a lack of agreement between the accounts given by Alaberni and Weber and those communicated to the *Philosophical Transactions* (London, vol. x.) by Cumulo Paderni, conservator of the Portici Museum. It is hoped, therefore, that among the papers recovered by Ruggiero there may be others which will shed light on what remains dark in the topography of the buried city.

Among the other works relating to Heracleum, in addition to those already quoted, may be mentioned De Brosses, *Lettre sur l'état actuel de la ville souterraine d'Hercule*, Paris, 1760; Selgueda de Corvejan, *Lettre sur les découvertes de Herculaneum*, Paris, 1761; Yverdon, 1770; David, *Les antiquités d'Herculaneum*, Paris, 1780; d'Ancona Gaetano, *Prospetto storico-fisico degli scavi d'Ercolano e di Pompei*, Naples, 1808; Venturi, *Primo Scavi di Ercolano*, Rome, 1748; and Romanelli, *Piaggio ad Ercolano*, Naples, 1811. A full list will be found in vol. i. of *Museo Borbonico*, Naples, 1824, pp. 1-11. (F. B.)

HERCULES (Old Latin, *Hercules*, *Hercles*) is the Latinized form of the mythical *Heraclēs*, the chief national hero of Hellas, who has part in all the most important myths of the generation before that which embraces the Homeric warriors at Troy. The name *Ἡρακλῆς* is compounded of *Hērā*, the goddess of the stars and of *κλῆς*, "glory." The thoroughly national character of *Heraclēs* is shown by his being the mythical ancestor of the Dorian dynastic tribe, while revered by Ionian Athens, Laelian Opus, and Æolo-Phenician Thebes, and closely associated with the Achaean heroes Peleus and Telamon. The Perseid *Alcmene*, wife of Amphytrion of Tiryns, was *Heraclēs*'s mother, Zeus his father (see *ALCMENE*). After his putative father he is often called Amphytrionides, and Alcides too, after the Perseid *Alcmene*, father of Amphytrion. His mother and her husband lived at Thebes in exile as guests of King Creon.

By the enmity of *Hērā* his life was through life, his birth was delayed, and that of *Eurythene*, son of *Sthenelus* of Argos, hastened, Zeus having in effect sworn that the elder of the two should rule the realm of *Perseus*. *Hērā* sent two serpents to destroy the new-born *Heraclēs*, but he strangled them. He was trained in all manly accomplishments by heroes of the highest renown in each, until he slew *Linus*, his instructor in music, with the lyre. Thereupon he was sent to tend Amphytrion's oxen, and at this period slew the lion of Mount *Cithæron*. By the suggestion of the *Minyans* of *Orchomenus* he won *Creon*'s

daughter, Megara, to wife. Her children by him he killed in a frenzy induced by Hera. After punishment he was sent by the Pythia to serve Eurystheus. The apologetics of Eurystheus on the *Choice of Hercules* between pleasure and virtue was founded on his obedience to the oracle. Thus began the cycle of the twelve labours —

- 1 Wrestling with the Nemean lion
- 2 Destruction of the Lernaean hydra
- 3 Capture of the Amazonian hind (a stag in art)
- 4 Capture of the boar of Erymanthus, while chasing which he fought the Centaurs and killed his female Chiron and Pholus, this homicide leading to Demeter's institution of *sympoties*
- 5 Cleansing of the stables of Augeas
- 6 Shooting the Stymphalian birds
- 7 Capture of the Cretan bull subsequently slain by Theseus at Marathon
- 8 Capture of the mauling mares of the Thracian Diomedes
- 9 Seizure of the grail of Hippolyte, queen of the Amazons
- 10 Binding the even of Geryon's land from Erythra in the far west, which incident involved many adventures in the coast lands of the Mediterranean, and the setting up of the " Pillars of Hercules " at the Straits of Gibraltar
- 11 Binding the golden apples from the garden of the Hesperides
- 12 Carrying Cerberus from Hades to the upper world

Most of the labours lead to various adventures called *adpepva*. Their common order and selection, due to Apollodorus and Diodorus Siculus, are later than Empirides, who omits 5, 6, and 7, and seems to count the victory over Cycnus in Pithon, the bearing of the heavens for Atlas, and the freeing of the seas from dangerous monsters in Homer we read of unspecified labours for Eurystheus, of the struggle with the sea monster of the Troad, and of wars. Herodotus mentions labours 1, 2, and 10, and the freeing of Prometheus. It is a mistake to suppose that legends of Hercules's struggles with monstrous embodiments of evil are not of high antiquity, though we cannot say positively which are old and which comparatively late. Some enumerations give only 10 labours. The late lists probably rest partly on astronomical ideas.

On Hercules's return to Thebes he gave his wife Megara to his friend and character Iolaus, son of Iphicles, and by beating Eurystus of Echalia and his son in a shooting match won a claim to the hand of his daughter Iole, whose family, however, except his brother Iphitus, withheld their consent to the union. Iphitus persuaded Hercules to search for Eurystus's lost oxen, but was killed by him at Thyrea in a frenzy. He consulted the Pythia about a cure for the consequent madness, but she declined to answer him. Whereupon he seized the oracular tripod, and so entered upon a contest with Apollo, which Zeus stopped by sending a flash of lightning between the combatants. The Pythia then sent him to serve the Lydian queen Omphale. He then with Telamon, Peleus, and Theseus took Troy. He next helped the gods in the great battle against the giants. He took part in the Argonautic voyage and the Calydonian boar hunt, made war against Augeas, and against Nestor and the Phryans, and restored Tyndareus to the sovereignty of Laconia. He sustained many single combats, one very famous struggle being the wrestling with the Libyan Antaeus, son of Poseidon and Gaia (Earth), who had to be held in the air, as he grew stronger every time he touched his mother. Earth Hercules withstood Ares, Poseidon, and Hera, as well as Apollo. The close of his career is assigned to Eleia and Trachis. He wrestles with Achelous for Deianeira ("destructive to husband"), daughter of Ceneus, king of Calydon, vanquishes the river god, and breaks off one of his horns, which as a horn of plenty is found as an attribute of Hercules in art. Driven from Calydon for homicide, he goes with Deianeira to Trachis. On the way he slays the centaur Nessus, who persuades Deianeira that his blood is a love charm. From Trachis

he wages successful war against the Dryopes and Lapithae as ally of Agamemnon king of the Dorians, who promised him a third of his realm, and after his death adopted Hyllus, his son by Deianeira. Finally Hercules attacks Eurystus, takes Echalia, and carries off Iole. Theseus, Deianeira, prompted by love and jealousy, sends him a tunic dipped in the blood of Nessus, and the unsuspecting hero puts it on just before sacrificing at the headland of Ceneum in Buboea. Mad with pain, he seizes Lichas, the messenger who had brought the fatal garment, and hurls him on the rocks, and then he wanders in agony to Mount Citha, where he mounts a pyre, which, however, no one will kindle. At last Peas, father of Philoctetes, takes pity on him, and is rewarded with the gift of his bow and arrows. The immortal part of Hercules passes to Olympus, where he is reconciled to Hera and wedds his daughter Hebe.

In one aspect Hercules is clearly a sun god, being identified, especially in Cyprus and in Thasos (as Melita), with the Tyrian Melkart. He is again a representative of endurance and effort in the cause of Hellenic civilization and enterprise. Scarcely of his exploits may be based on actual achievements of tribes and leaders of men, but it is impossible to unravel satisfactorily the tangled strands which make up this highly elaborate myth, though the separate existence of some is clearly discernible. The close connexion of the hero with both Thebes and Argos suggests actual relations between the two states. The Lydian episode shows traces of Eastern influence. The second, fifth, and sixth labours may be solar, but yet they suggest reclamation of marsh land. The third and twelfth are the most obviously solar, the horned hind representing the moon, and the carrying of Cerberus to the upper world an eclipse. It may be admitted as highly probable that the last episode of the hero's tragedy is a complete solar myth developed at Trachis. The winter sun is seen rising over the Cenean promontory to toil across to Mount Citha and disappear over it in a bank of fiery cloud. The fatality by which Hercules kills so many friends as well as foes recalls the destroying Apollo, while his career frequently illustrates the Delphic views on blood guiltiness and expiation. As Apollo's champion Hercules in Dardaniophoria, and fights Cycnus and Amyntor to keep open the sacred way from Tempe to Delphi. As the Doian tutelary hero, Tyndareus and Agamemnon as patron of maritime adventure (*ηγεμῶνες*) he struggles with Nereus and Triton, slays Phryx and Balaam, and perhaps captures the wild horse and oven, which may stand for pinales. As a god of athletics he is often a wrestler (*παλαστής*), and founds the Olympian games. In comedy and occasionally in myth he is depicted as voracious (*βουβόγυος*). He is also represented as a "Resting" (*ἀναπαύων*) Hercules is, as at Thebes, Lydian and near Humeia, the natural protector of hot springs in conjunction with his protectress Athena, who is usually depicted attending him on ancient vases. The glorified Hercules was worshipped both as a god and a hero. In the Attic deme Melita he was invoked as *Διέλειος* ("Heliopolitan"), at Olympia as *καλλίπυκος* ("Nobly-victorious"), in the rustic worship of the Cithaerans as *κορυβώτης* (*ἀλφειῶτης*, "lionate"), by the Erythraeans of Ionia as *ἰσχυρόν*, "Canker worm-slayer." In Italy he was, like Apollo, Musagetes ("Leader of the Muses"). He was *σωτήρ* ("Saviour"), i.e., a protector of voyagers, at Thracian and Strymon, and in Italy, where titles were vowed to him to be spent in entertainment. Games in his honour were held at Thebes and Marathon. In early poetry, as often in art, he is an archer, afterwards a club-wielder and fully-armed warrior. In early art the adult Hercules is bearded, but not long-haired. Later he is sometimes youthful and beardless, always with short curly hair and thick neck, the lower

part of the brow prominent. A lion's skin is generally worn or curled. Lysippus worked out the finest type of sculptured Hercules, of which the Farnese by Glycon is a grand specimen. The infantine struggle with serpents was a favourite subject.

Quite distinct was the Idoean Hercules, a Croton Dactyl connected with the cult of Rhea or Cybele. The Greeks recognized Hercules in an Egyptian deity *Chom* and an Indian *Dorcas*, not to mention personages of other mythologies. Hercules is supposed to have visited Italy on his return from Erythra, when he slew Ocean, son of Vulcan, the giant of the Aventine mount in Rome, who had stolen his oxen. To this victory was assigned the founding of the *Iris meaeum*. With respect to the Roman relations of the hero, it is manifest that the native myths of *Recuranus*, or *Sancus*, or *Dius Fidius*, were transferred to the Hellenic Hercules.

The best account of the Hercules myth and cult is by L. Preller, *Griechische Mythologie*, 2d ed., Berlin, 1875. See also Hüllm., *Die Hellenische Romania*, 2 vols., Munich, 1850, and Bréal, *Hercules et Omphale*, Paris, 1863. (C A M F)

HERDER, JOHANN GOTTFRIED VON (1744-1803), one of the most prolific and influential writers that Germany has produced, was born in Mohrungen, a small town near Königsberg, in 1744. Like his contemporary Lessing, with whose literary aims his own had so much in common, Herder had throughout his life to struggle against adverse circumstances. His father was poor, having to put together a subsistence by uniting the humble offices of sexton, choir singer, and petty schoolmaster. Gottfried seems to have got some rudimentary instruction from his father, after which he was sent to the grammar school (gymnasium) of his native town. The mode of discipline practised by the pedantic and irritable old man who stood at the head of this institution was not at all to the young student's liking, and the impression made upon him stimulated him later on to work out his projects of school reform. The hardships of his early years drove him to introspection and to solitary communion with nature, and thus favoured a more than proportionate development of the sentimental and poetic side of his mind. When quite young he expressed a wish to enter the church, but his aspirations were somewhat rudely discouraged by the local clergyman. In 1762, at the age of eighteen, he went up to Königsberg with the intention of studying medicine, but finding himself unequal to the operations of the dissecting-room, he abandoned this object, and by the help of one or two friends and his own self-supporting labours, followed out his earlier idea of the clerical profession by joining the university. There he came under the influence of Kant, who was just then passing from physical to metaphysical problems. Without becoming a disciple of Kant, the young Herder was deeply stimulated to fresh critical inquiry by that thinker's revolutionary ideas in philosophy. To Kant's lectures and conversations he further owed something of his large interest in cosmological and anthropological problems. Among the writers whom he most carefully read were Plato, Hume, Shaftesbury, Leibnitz, Diderot, and Rousseau. Another personal influence under which he fell at Königsberg, and which was destined to be far more permanent, was that of Hamann, "the northern Mage." This writer had already won a name, and in the young Herder he found a mind well fitted to be the receptacle and vehicle of his new ideas on literature. From this vague, incoherent, yet clever writer our author acquired some of his strong feeling for the natural and poetic element in poetry, and for the earliest developments of natural literature. Even before he went to Königsberg he had begun to compose verses, and at the age of twenty he took up the pen as a chief occupation. His first published writings were occasional poems

and articles contributed to the *Königsberg Journal*. Soon after this he got a double appointment at Jena, as assistant master at the cathedral school, and as curate to the suburban churches. In this busy commercial town, in somewhat improved pecuniary and social circumstances, he developed the main ideas of his writings. In the year 1767 he published his first considerable work *Fragmente über die neuer deutsche Literatur*, which at once made him widely known and secured for him the favourable interest of Lessing. From this time he continued to pour forth a number of critical writings on literature, art, &c. His bold ideas on these subjects, which were a great advance even on Lessing's doctrines, naturally excited hostile criticism, and in consequence of this opposition, which took the form of aspersions on his religious orthodoxy, he resolved to leave Jena. He was much carried away at this time by the idea of a radical reform of social life in Livonia, which (after the example of Rousseau) he thought to effect by means of a better method of school-training. With this plan in view he began (1769) a tour through France, England, Holland, &c., for the purpose of collecting information respecting their systems of education. It was during the solitude of his voyage to France, when on deck at night, that he first shaped his idea of the genesis of primitive poetry, and of the gradual evolution of humanity. Having received an offer of an appointment as travelling tutor and chaplain to the young prince of East-Prussia, he abandoned his somewhat visionary scheme of a social reconstruction of a Russian province. He has, however, left a curious sketch of his projected school reforms. His new duties led him to Strassburg, where he met the young Goethe, on whose poetical development he exercised so potent an influence. At Darmstadt he made the acquaintance of Caroline Flachsland, to whom he soon became betrothed, and who for the rest of his life supplied him with that abundance of consolatory sympathy which his sensitive and rather querulous nature appeared to require. The engagement as tutor did not prove an agreeable one, and he soon threw it up (1771) in favour of an appointment as court preacher and member of the consistory at Buckeburg. Here he had to encounter bitter opposition from the orthodox clergy and their followers, among whom he was received as a free-thinker. His health continued poor, and a fistula in the eye, from which he had suffered from early childhood, and to cure which he had undergone a number of painful operations, continued to trouble him. Further, pecuniary difficulties, from which he never long managed to keep himself free, by delaying his marriage, added to his depression. The correspondence between Herder and Caroline Flachsland indicates a relationship which offers a curious parallel and contrast to that of Lessing and his future wife under very similar circumstances. Notwithstanding these trying circumstances he resumed literary work, which his travels had interrupted. For some time he had been greatly interested by the poetry of the north, more particularly Percy's *Rosalind*, the poems of "Osian" (in the genuineness of which he like many others believed), and the works of Shakespeare. Under the influence of this reading he now finally broke with classicism and became the leader of the new "Sturm und Drang" movement. He co-operated with a band of young writers at Darmstadt and Frankfurt, including Goethe, who in a journal of their own sought to diffuse the new ideas of Herder. His marriage took place in 1773. In 1776 he obtained through Goethe's influence the post of upper court preacher and upper member of the consistory at Weimar, where he passed the rest of his life. There he enjoyed the society of Goethe, Wieland, Jean Paul (who came to Weimar in order to be near Herder), and others, the patronage of the court, with whom as a preacher he was very popular, and an opportunity of carrying out some of

his pet ideas of school reform. Yet the social atmosphere of the place did not suit him. His personal relations with Goethe again and again became embittered. He had not the poet minister's liking for the elegant frivolities of court life, while the efforts of Goethe and Schiller to make Weimar a dramatic centre repelled his austere moral nature. All this, added to ill-health, served to intensify a natural irritability of temperament, and the history of his latter Weimar days is a rather dreary page in the chronicles of literary life. He had valued more than anything else a teacher's influence over other minds, and as he began to feel that he was losing it he grew jealous of the success of those who had outgrown this influence. Yet while presenting these unlovely traits, Herder's character was on the whole a worthy and attractive one. This seems to be sufficiently attested by the fact that he was greatly liked and esteemed, not only in the pulpit but in private intercourse, by cultivated women like the countess of Buckeburg, the duchess of Weimar, and Frau von Stein, and, what perhaps is more, was exceedingly popular among the gymnasium pupils, in whose education he took so lively an interest. While during the last years of his life he produced much that is of little value, he wrote also some of his best works, among others his collection of popular poetry, *Stimmen der Völker*, his most notable original poem, the *Cul*, his celebrated work on Hebrew poetry, *Vom Geist der hebräischen Poesie*, and his *opus magnum*, the *Ideen zur Philosophie der Geschichte*. Towards the close of his life he occupied himself like Lessing with speculative questions in philosophy and theology. The boldness of some of his ideas cost him some valuable friendships, as that of Jacobi, Lavater, and even of his early teacher Hamann. He died in the year 1803, full of new literary plans up to the very last.

Herder's writings were for a long time regarded as of temporary value only, and fell into neglect. Recent criticism, however, has tended very much to raise their value by tracing out their wide and far-reaching influence. The number of publications relating to Herder that have appeared during the last few years shows that there is a revival of interest in this writer. His writings are very voluminous, and to a large extent fragmentary and devoid of artistic finish, nevertheless they are nearly always worth investigating for the brilliant suggestions in which they abound. His place in German literature has already been faintly indicated in tracing his mental development. Like Lessing, whose work he immediately continued, he was a pioneer of the golden age of this literature. Lessing had given the first impetus to the formation of a national literature by exposing the folly of the current imitation of French writers. But in doing this he did not so much call his fellow countrymen to develop freely their own national sentiments and ideas as send them back to classical example and principle. Herder on the contrary fought against all imitation as such, and bade German writers be true to themselves and their national antecedents. As a sort of theoretic basis for this adhesion to national type in literature, he conceived the idea that literature and art, together with language and national culture as a whole, are evolved by a natural process, and that the intellectual and emotional life of each people is correlated with peculiarities of physical temperament and of material environment. In this way he became the originator of that genetic or historical method which has since been applied to all human ideas and institutions. Herder was thus an evolutionist, but an evolutionist still under the influence of Rousseau. That is to say, in tracing back the later acquisitions of civilization to impulses which are as old as the dawn of primitive culture, he did not, as the modern evolutionist does, lay stress on the superiority of the later to the earlier stages of human development, but rather became enamoured of the simplicity

and spontaneity of those early impulses, which, since they are the oldest, easily come to look like the most real and precious. Yet even in this way he helped to found the historical school in literature and science, for it was only after an excessive and sentimental interest in primitive human culture had been awakened that this subject would receive the amount of attention which was requisite for the genetic explanation of the later acquisitions of the species. This historical idea was carried by Herder into the regions of poetry, art, religion, language, and finally into human culture as a whole. It colours all his writings, and is intimately connected with some of the most characteristic attitudes of his mind, a quick sympathetic imagination, a fine feeling for local differences, and a scientific instinct for seizing the sequences of cause and effect.

Herder's works early change themselves in an ascending series, corresponding to the way in which the genetic or historical idea was developed and extended. First come the works on poetic literature, art, language, and religion in special regions of development. Secondly, we have in the *Ideen* a general account of the process of human evolution. Thirdly, there are a number of writings which, though infused in interest to the others, may be said to supply the philosophic basis of his leading ideas. (1) In the region of poetry Herder sought to persuade his countrymen, both by example and precept, to return to a natural and spontaneous form of utterance. His own poetry is voluminous, and as a whole has but little value. Herder was a skilful verse maker, but hardly an original poet. His best poetry consists of a translation of a poem of some, in which he shows a rare sympathetic insight into the various feelings and ideas of peoples as unlike as Greek and Latin, and Egyptian, Indian and Chinese. In the *Phrygians* he mentions that German poetry and its living in them is extinguished by the influence of the imitation of German writers to be classic, as Lessing had ridiculed that of the ancients to be French. "Let us," he says, "be classicist writers, adapting ourselves to the peculiarities of our people and our language, whether we are classic poetry may find out." In his sweeping condemnation of contemporary writers, he does not exempt even Klopstock, with whose feeling for nature he is so much in sympathy, but whose poems appear to him to be too much of a kind. He looked at poetry as a kind of "protest among the people, which changes its form according to language, manner, habits, according to temperament and climate, may, even according to the amount of difficult nations." The fact of the absorption of a national poetry, he illustrated with great fulness and richness in the case of Homer, the nature of whose works he was one of the first to elucidate, the Hebrew poets (*Geist der hebräischen Poesie*), and the poets of the north as typified in "Osai." This same idea of the necessary relation to national character and circumstance is also applied to dramatic poetry, and more especially to Shakespeare. Lessing had done much to make Shakespeare as known to Germany, but he had regarded him in contrast to the French classic. Herder, on the contrary, contrasted the Greek dramatic poets, and accordingly did not bring out his essentially modern and Teutonic character. Herder does this, and in doing so shows a far deeper understanding of Shakespeare's genius than his predecessors. He also shows a deeper criticism of *Hamlet*, *Othello*, and other plays as worthy of being read along with those of later German writers. (2) The value of art contained in Herder's *Ästhetik*, *Ästhetik*, is also chiefly valuable as a correction of the excessive into which it was then falling. It had betrayed Winkelmann and Lessing, by help of his fundamental idea of national individuality. It argues against the setting up of classic art as an unchangeable type, valid for all peoples and all times. He was one of the first to bring to light the character of the excellences of Gothic art. Beyond this, he eloquently pointed out the value of painting as a distinct art, which Lessing in his desire to mark out the formative value from poetry and music had, although it was with nature. He regarded this as the art of the future, while the others were rather the art of the origin of truth. Painting being based on a firm sculpture, because lacking the third dimension of space, and a kind of dream, admitted of much greater freedom of the spirit than the first. Herder had a genuine appreciation for early German poetry, and helped to awaken the modern interest in Altdenkdichtung. (3) By his work on language *Über den Ursprung der Sprache*, Herder may be said to have laid the first link in the chain of the science of comparative philology and that discipline was of the utmost value in the origin of language. It was specially directed against the supposition of a divine communication of language to man. It meant argument that speech is a necessary outcome of the special arrangement of the mental forces which distinguish the various families of man from his brethren of reflection. "If," Herder says, "it were impossible to others how a human mind could invent language, it is as unreasonable to know how a human mind could be what it is without discovering language for itself." The water does not make itself

ness of the fact of man's spiritual organs endowments which one might expect from his general conception of the relation of the physical and the mental in human development. (4) Haeckel's services in laying the foundations of a comparative science of religion and mythology are of great value. His ideas have somewhat of a philosophical and speculative character. In opposition to the general spirit of the 18th century he argues, by means of his historic sense, the naturalness of religion, its relation to man's wants and impulses. Thus with respect to early religious beliefs he rejected Hume's notion of it as a development out of the fears of primitive man, in favour of the theory that it represents the first attempts of our species to explain phenomena. He is not without association of religion with mythology and primitive poetry. As to later forms of religion, he appears to have held that they owe their vitality to their embodiment of the deep spiritual feelings of our common humanity. His high appreciation of Christianity, which contrasts with the contemporary estimate of the contemporary rationalists, rested on a firm belief in its essential humanity, to which fact, not to conscious deception, he attributes its success. His exposition of this religion in his *Customs and Manners* was simply an unfolding of the moral side. In his later life, as we shall presently see, he found his way to a new culture, which for his religious beliefs. (5) Haeckel's masterpiece, the *Atlas*, has the limitations of an expounding the whole of human life in its close connection with the nature of man's physical constitution. Man is viewed as a part of nature, and all his vital different forms of development as strictly natural processes. It thus avoids the shallow materialism of Kant, which opposes human development conceived as the gradual manifestation of a growing faculty of rational life to the operations of physical nature. Haeckel divides man's history as "a process through his history of human development, from the lowest to the highest stage, and place." The *Atlas* shows us that Haeckel is an evolutionist in the natural, historical, and not after the most modern voluntaristic.¹ The lower forms of life picture man in several degrees of approximation to the process of evolution, and are regarded as representing necessary antecedent conditions of human events in the genetic method is applied to varieties of man, not to man as a whole. It is worth noting, however, that Haeckel in his premonitory tendency away of thinking of man as a species, and man very much is made familiar to us by Mr. Spencer and Mr. Darwin. There is a passage in book 5, chap. 1, which unequivocally testifies to Haeckel's view, which was mentioned, we read: "Among millions of creatures whatever could preserve itself abides, and still after the lapse of thousands of years remains in the great humanous order." Wild animals and birds, criminals and gamblers, idiots, weaklings, slaves, soldiers and men are adapted to each other." With this he compares a passage in the *Ursprung der Sprache*, where there is a common admiration of Mr. Spencer's idea that intelligence, as distinguished from instinct, arises from a growing complexity of action, or, to use Haeckel's words, from the substitution of a man for a less continued action.² Haeckel is more successful in tracing the early developments of particular peoples than in constructing a scientific theory of evolution. His history he said to have laid the foundations of the science of primitive culture as a whole. His account of the first dawnings of culture, and of the under-Ordnung civilisations, is marked by genuine insight. In the ethical domain of human culture he is less successful, and is less skilful hand. Although this work is rich in suggestion to the philosophic historian and the anthropologist, though marked by man's vagueness of conception and a distance of generalisation. (6) Of Haeckel's propensity to overstate speculative little needs to be said. It is too much under the way of feeling and concrete imagination to be capable of great things in abstract thought. It is generally admitted that he had no accurate knowledge of human history, whose main line is abstracted, or of Kant, whose ethical philosophy he so fiercely attacked. His sympathy with the one and his antipathy to the other was intimately connected with the essential character of his nature, which was speculative, though in the abstract, regarded things in their concrete surroundings rather than in abstract isolation. It was not one step more to the man who had learnt to view poetry, art, language, &c., in their connection with social and physical surroundings, to bring together the great aggregates of material and spiritual phenomena under one total conception of a single substance or God. Haeckel's *Spencerism*, which is set forth in his little work, *Von Spencer und Evolutionismus*, is a *verworrenes Netz*, is much less logically conceived than Lessing's. It is the religious aspect of it which attracts him, the presentation in form of an object of devotion, the feelings and the intellect. With respect to his attacks on the critical philosophy in the *Metaphysik*, it is easy to understand how his concrete mind, ever alive to the unity of things, instinctively rebelled against that analysis in question of the mental processes which Kant attempted.

However crude and hasty this author's investigation, it helped to direct philosophic reflection to the unity of mind, and so to develop the post-Kantian line of speculation. Haeckel was much attracted by Schelling's writings, but appears to have doubted Hegelism because of its abstractness, and seems to have to myself. In the *Welt*, a work directed against Kant's *Critique of Judgment*, Haeckel argues for the close connection of the beautiful and the good. "To his mind the content of art, which he conceived as human feeling, and human feeling in its completeness, was more valuable than the form, and so he was primarily led to emphasize the moral element in art. Thus his theoretic opposition to the Kantian aesthetics is but the reflexion of his practical opposition to the idealism of the German poets."

The most valuable original sources of information on Haeckel, next to his own works (of which a new edition, edited by P. Bogen, is now appearing), are the *Darstellung eines dem Lehrer J. G. von Herder, in dem Haeckel's Leben*, by his son, and his letters, edited by Dammann. Haeckel's personality, the general tasks which he had, and a full account of Haeckel in a number of recent biographical works. Among them the fullest are On the *Atlas* of the *Herzogliche Bibliothek in Altona* (which unfortunately does not deal with the latter part of his life) and R. B. Haeckel's *Herzogliche Bibliothek in Altona* (which unfortunately does not deal with the latter part of his life).

HEREFORD, an inland English county on the south border, Welsh border, is bounded on the N by Salop, S by XIV Monmouthshire and Gloucestershire, W by Worcestershire, and W by Radnorshire and Brecknockshire. Its peculiar shape is indented by spurs of adjacent counties, and its outlying parts have by an Act of William IV 7 and 8 been incorporated with the counties to which they are situated. Its greatest length from Ludlow to the Dward Hills, near Monmouth, is 38 miles; its greatest breadth from Cradley to Clifton, near Hay, 35. Its area according to the census of 1871 is 532,598 statute acres, or 822 square miles. It is divided into 11 hundreds and 221 parishes, and is a bishop's see, of which the cathedral city is the centre of the county.

Its chief rivers are the Wye and Lug. The former, rising near the source of the Severn on the summit of Plimlimon, forms the boundary between Herefordshire and Radnor; it enters Herefordshire near Clifton, and flowing past Hereford, Ross, and Monmouth, falls into the Severn near Chepstow. A striking feature of the Wye is its sinuosity, especially between Hereford and Monmouth. Its never very effectual navigation has been put on end to by railway enterprise, and its salmon fisheries are now so protected by legal enactment that there is no longer a danger of Hereford apprentices being fed on salmon "ad nauseam." The Lug, a first-rate trout stream, rising in Radnorshire, enters Herefordshire near Prestegyn, and, passing by Aymestry, Llangollen, and Leominster, joins the Wye below Maidenford Bridge, south-east of Hereford. The Arrow also rises in Radnorshire, and flowing past Kingston and Pembroke joins the Lug near Monkland, and the Frome, having its source near Bismyng, joins the same river near Mordford, while the Ladden runs past Ledbury to join the Severn near Gloucester. All these, as well as the Teme, a boundary line of the north-east of the county, are more or less famous trout streams.

The soil is generally main and clay, but in various parts contains calcareous earth in mixed proportions. The soil is so tenacious and retentive of water, on the one hand, is a stiff and often reddish clay. In the south is found a light sandy loam. The subsoil is mostly limestone, in some parts the Old Red Sandstone, and a species of red and white variegated marble. Where the soil does not rest on limestone, it is sometimes a siliceous gravel, or contains fuller's earth and yellow ochres. Limestones, quarried at Aymestry and Nash to the north-west of the county, and at Ledbury, Woolhope, and elsewhere, is successfully applied as a manure for arable land and pasture. For the physical history of the county reference must be made to Murchison's *Strata*, or Symonds's *Recess of the Rocks*, where the upheaval and denudation in the Woolhope valley and over the central dome of Haulwood and similar questions are discussed.

¹ See article *Evolutionism*, vol. viii pp. 760, 761.

² Haeckel's relation to modern evolutionism is dealt with in F. von Hartmann's *Atlas des Vorlesungen Darwin*.

The climate is variable, owing to the damp and foggy which moisten the earth and account for its great wetness, as well as to its large proportion of timber, not only in parks and on landed estates, but almost on every hedge-row. In spite, however, of the prevalence of rheumatism, Herefordshire is reckoned healthy, ranks high in the statistics of longevity, and enjoys a comparative immunity from diseases of the respiratory organs.

The surface of the county is undulating in long ridges, as if by arbutan uncen ripples. Ash and oak coppices and larch plantations clothe its hill sides and rivets. Its lowlands are studded with pear and apple orchards, of the fruitfulness of which Herefordshire, sometimes, as well as Kent, is called the garden of England. The apple crop, generally large, is notorious one year out of four. Twenty hogheads of cider, which is the county beverage, have been made from an acre of orchard, twelve being the ordinary yield. Hops are another staple of the county, the vines of which are planted in rows on ploughed land. As early as Camden's day a Herefordshire ridge coupled Woolley lies with Leominster here, suggesting the county's capacity to produce fine wheat and barley, as well as hops. On the Worcestershire border there 10,000 acres are taken up in hop plantations, and about Ludlow the clay lands are noted for whort and hops.

Herefordshire is also famous as a breeding county for its cattle of light red hair, with mottled or white faces and sleek silky coats. The Herefords are stalwart and healthy, and though not milk-pails, put on more meat and fat at an early age, in preference to food consumed, than almost any other variety. They produce the finest beef, and are more cheaply fed than Devon or Durham, with which they are advantageously crossed. As a fowl county Herefordshire does not rank high. Its small, white, fat, boned, symmetrical breed of sheep known as "the Ryeland," from the district near Ross, where it was bred in most perfection, make the county long famous both for the flavor of its meat and the mellow like texture of its wool. Tails, six of this that it was best known as "Lampeter out," and the finest in all England. In its original form the breed is extinct, crossing with the Leicester having improved size and stamina at the cost of the fleece, and the chief breeds of sheep on Herefordshire farms at present are Shropshire Downs, Cotswolds, and Radnor, with their crosses. Agricultural horses of good quality are bred in the north, and saddle and coach horses may be met with at the fairs, especially at the chief fairs of sheep on Herefordshire farms at present are Shropshire Downs, Cotswolds, and Radnor, with their crosses. Agricultural horses of good quality are bred in the north, and saddle and coach horses may be met with at the fairs, especially at the chief fairs of sheep on Herefordshire farms at present are Shropshire Downs, Cotswolds, and Radnor, with their crosses.

The county has no manufactures to speak of. Woollen goods have never been a successful staple of trade at Hereford, yarn and coarse woollens are the lowest, in small quantities at Leominster and Kingston. There are no foundries for agricultural implements at Kingston and Ross.

The agricultural returns of Great Britain for 1879 give the following statistics for Herefordshire.	
Corn crops (two thirds being wheat and barley)	108,262 acres
Green crops (of which two thirds are turnips and swedes)	84,671 "
Grass under rotation	40,092 "
Permanent pasture	246,638 "
Hops	5,947 "
Beet, fallow, and uncropped arable land	11,098 "

Live Stock

Horses	21,200
Cattle	77,402
Sheep	340,711
Pigs	34,109

In all but the last item the live stock presents a marked increase on 1878, in corn crops there is a decided retrograde, in green crops and permanent pasture a considerable increase, and the area in hops is the same as in the previous year.

According to the preliminary return of 1878 the county was divided among 13,781 proprietors, owning a total area of 506,650 acres, with a rental of 2,921,640 £. Of the population, 9085 (66 per cent) held less than 1 acre, and 2178 (16 per cent) between 1 and 10 acres. The owner-holdings are—A. B. Ashburton, Hampton Court, Leominster, 10,559 acres, A. B. Boughton Knight, Downton Castle, 10,081, R. D. Hanley, Downton Bryan, 8908, Sir George H. Cornwall, Moccas, 6946, Lord Bateman, Shobdon Court, 6400, Lord George Cecil, 6668, Lord Ashburton, 6683, Major Mervyn Chiche, Whitfield, 5799, Lady

Emily Foley, Stoke Edith Park, 5660, Sir Henry Cottrell, Gunons, 5066, Sir Henry E. Sudcliffe, Stunhope, Holm Lacy, 5039, Major Peppes, Gunstone, 1928.

In Herefordshire inland navigation was represented in the early part of the century by the Gloucester and Newnham and Ludlow canal, but this has been bought up for railway purposes, and the canal from Leominster to Woodlinton, and thence extended to Tenbury and Stowport, has the credit to exist. Hereford is an important railway centre, the Hereford, Ross, and Gloucester line is now amalgamated with the Great Western, the Shrewsbury and Hereford railway traverses the county southward from Woodlinton, via Leominster, to Hereford. The Worcester and Hereford, via Midland, connects the county, town with Oxford and London by an alternative route of the Midland and Great Western, and the west of the county is served by the Midland line from Hereford to Bacon, while the Hereford, Abingdon, and Bristol line accommodates the south-west. Branch lines run from Eardisley to Kingston and Presteigne, from Ross to Monmouth, from Woodlinton to Bromyard, and from Leominster to Kingston.

The latest statistics of public elementary schools show about 135 Churches of England, national or parishial schools, 6 board schools, 3 British and Foreign and 8 Roman Catholic schools in the county. Its population, which was 115,489 in 1851, had increased in 1871 to 125,870. Herefordshire is represented in parliament by 6 members—3 for the county, 2 for Hereford city, and 1 for the borough of Leominster. Its towns, besides Hereford, are Ross, Leominster, Ludbury, Kingston, and Bromyard, of these, Ross and Leominster are the most considerable, though Kingston, from its position on the Welsh border, does a brisk trade. In Kingston, Bromyard, Ludbury, and Ross, and such large villages as Woolley and Okeston, survive many picturesque timber and plaster houses of the 15th and 16th centuries.

History.—The earliest known inhabitants of the county were the Silures, whose stout resistance to the Romans provoked the emperor Claudius to the war of extermination in which he defeated Suetonius Paulina, but the latter prince, who had been the final stand-point against the Romans. Traces of the Dracis are found at Wigmore, and in 912 they resisted the Danes, and carried off from Aikenhead the bishop of St. David's, who had to be redeemed with a huge ransom. By the Normans the county was held on the tenure of repelling the Welsh, and for centuries the Maccles of Wales were a detestable gnomes. In the reign of Henry II. the feud between Maud and Stephen shows was fighting in the name of Herefordshire. When the barons rose against Henry III. their hostilities affected this county, and it was the success of a plot of the earl of Gloucester, Roger Mortimer, and others to dethrone Edward's escape out of De Montfort's hands that led to his flight to Wigmore, and the subsequent death of the barons at Evesham. In the Wars of the Roses a battle was fought on February 2, 1467, at Mortimer's Cross, in a field called between Ludlow and of March (between Fiddler's Hill), and Sir John Tudor and James Butler, earls of Arundel and Wiltshire, in the hall of Queen Margaret, which resulted in the victory of the Yorkists. The March was incorporated in the reign of Henry VIII. in the war between Charles I. and his parliament at Herefordshire, and severely for its loyalty, and Hereford, Goodrich, and Ludlow in the civil wars, all but the last ending in the king's party. The only place historic monument in the county is the cromlech of Arthur's Stone on the hill above Badbury. A line of British entrenchments stretches from the Swynn and from Malvern, where an outwork is still known as the Herefordshire (Gloum) to Aconbury on Weston under Penryn, and thence by a short route under Caplan Hill to Migma or Aconbury, and thence by a longer route to Monmouth, Usk, Abingdon, and so through Magna to Shrewsbury. King's Dyke, the boundary line of defence against the Welsh, is still to be seen at Monmouth, Ludlow, Llanymahall, and beyond Kingston. Old's is a natural place, the scene of its murder of Ethelbert, was at Sutton Walls, a little north of Hereford. The ruins of several Norman castles still exist at Wigmore, Clifford, Goodrich, and Hampton Bryan. Among the most interesting churches of that period are one of the most remarkable structures of rare Irish Norman architecture, viz., Kilpeck, Moccas, and the arches of old Shobdon church, in which the Cistercian church of Abbot Dore, and the fine old churches of Leighton and Leominster.

Hereford, the capital city of the above county, is situated on the left bank of the Wye, which is crossed there by a bridge of six arches. The seat of Hereford was detached from Lichfield in 673, Putta being its first bishop. The removal of murdered Ethelbert's body from Marden

to Hereford led to the foundation of a superior church, reconstructed by Bishop Athelstan, and burnt by the Welsh in 1055. Recommended in 1079 by the first Norman bishop, Robert of Lorraine, it was carried on by Bishop Reynelm, and completed in 1148 by Bishop R. de Beun. The lady chapel, clerestory of the choir, and north transept date between 1226 and 1289, while successive additions and reconstructions have extended over 450 years. In 1786 the great western tower fell and carried with it the west front and the first bay of the nave, since which date there have been two modern restorations, in 1842 and 1893. The total length of the cathedral is 342 feet, inside 337 feet 5 inches, the nave outside is 158 feet 6 inches, the choir from screen to retables

Plan of Hereford Cathedral.

75 feet 6 inches, and the lady chapel 93 feet 5 inches. The breadth of the nave (span of roof) is 31 feet 4 inches, the nave and aisles, internally, 73 feet 4 inches, and the central transept 146 feet 2 inches. The height of choir is 62 feet 6 inches, of nave 64 feet, of lantern 96 feet, of tower to top of the leads 140 feet 6 inches, and to the top of the pinnacles 165 feet. The pillars and arches of the nave, the north and south arches of the choir, and the triforium are Norman in their architecture, as is also the font; the lady chapel, the clerestory, and stone vaulting, Early English. The north transept is of the date of Bishop Aquablanca (1245-68), the south-east transept of Late Decorated. As the late Sir Gilbert Scott pointed out at Hereford to the Archaeological Institute, but for the fall of the western tower, the consequent curtailment of the nave, and other solecisms, few cathedrals could offer so complete a field of progressive architectural study from Early Norman to latest Perpendicular. The cathedral can boast some fine monuments, notably St Thomas of Cantilupe's shrine in the north transept, and Bishop Aquablanca's tomb. The "Mappa Mundi," compiled in 1300

or thereabouts by a monk of Lincoln, one of the largest and most curious of all the old maps, is preserved in the south choir aisle. The bishop's palace overlooks the Wyre on the south of the cathedral, and to the left of it lies the castle green, the site of the historic castle, which is utterly effaced. One only of the six gates of the old walls is still to be seen, but there are ruins of the Black Friars' Monastery in Widemarsh, and a mile out of Hereford on the Brecon Road, the White Cross, erected in 1347 by Bishop Charlton, and restored by Archdeacon Lord Saye and Sele, commemorates the departure of the Black Plague. For its loyalty and sufferings in the civil war Charles I. gave the city its motto "Invicta fidelitatis premium." It was incorporated in 1189 by Richard I., and is governed by a municipal council, consisting of a mayor, 6 aldermen, and 18 councillors. It has no manufactures. Its population at the census of 1871 numbered 18,355, or an increase of more than a third in twenty years; its area, was 4969 acres. Its public buildings are the shire hall in St Peter's Street, in the Grecian Doric style, with a statue of Sir George Cornwall Lewis in front of it; the corn-exchange (1855), the Rankin free library and Woolhope Club museum in Broad Street, and the Herefordshire middle-class college. The most noteworthy churches are All Saints and St Peter's.

For the bibliography of the city and county of Hereford, see Dancumb's *Collections for a History*; Robinson's *Castles, Monasteries, and Mansions*, 2 vols., 1869 and 1878; Webb's *History of the Civil War in Herefordshire*, 1879; Haverall's *Points Herefordenses*; *Quarterly Review*, art. "Herefordshire," July 1879; and the *Woolhope Transactions*. (J. D.A.)

HERENCIA, a town of Spain in the province of Ciudad Real, New Castile, is situated in a fertile, hilly region, near the junction of the rivers Gíguela and Valdespino, about 80 miles south of Madrid. Soapmaking is the chief industry; coarse cloth, wax, and chocolate are also manufactured. Wheat, barley, vines, and olives are grown in the neighbourhood, where also there is excellent pasturage. Population about 7300.

HEREROLAND, or DAMARALAND, a region of South-Western Africa, stretching north from the Kuaisip to the Cunene, so called from the native race known to the Namaqua as Herero and to the Cape colonists as Damara (Dama, or Dama). The north-west portion is also known as Kaokoland.

According to the treaty of Okahandja, by which, in 1876, the country came in some sort under British protection,¹ the boundary line is fixed as coinciding in the south with the line of latitude passing through Rehoboth or Annis (a mission station in 17° 5' E. long. and about 165 miles from the coast), thence in a straight line to Otyimbinde (Tunobis or Riat Fontein), in 20° 53' E. long. and 22° 5' S. lat., thence northwards to Otyindarmia, and finally from that place westwards along the Omurumba Ovambo to the Cunene. The territory thus defined has an estimated area of 100,000 square miles; and of this about 35,000 square miles were marked out as a British reservation, bounded by a line drawn from Rehoboth to Otyimbinde, thence north-west to Otyituo, about 19° E. long. and 20° S. lat., thence west to Otyahavita, and south to the neighbourhood of Mount Erongo. According to Palgrave the total population of Hereroland is 121,150, of whom 85,000 are Herero proper, 30,000 Hill Damara, 3000 Bushmen, 1500 Namaqua, 1500 Bastards, and 150 Europeans. In a paper in *Petersmann's Mittheilungen*, 1878, based on information from the Rheinish missionaries, the total is given as 184,000, of whom 110,000 are Herero (80,000 Ova Herero and 30,000 Ova-mbanderu),

¹ See *Damara and Namaqua Land: Report of W. Coates Palgrave, Esq., special commissioner to the trustees of the Orange River, of his mission to Damaraland and Great Namaqualand in 1876*, Cape Town, 1877.

to it, a heresy was a crime with punishment annexed, and therefore was capable of legal definition. It was an offence in canon law, and it was also for long an offence according to civil law. The theological meaning, and the definitions according to canon law and according to civil law respectively, are all different from each other and must be separately explained.

1 *The Theological Sense of the Term*.—The early Christian writers say a great deal about heresy, but commonly refrain from telling what it is. They describe heretics, but they only denounce heresy. It is vain to look for a definition of it in Irenæus's *Against Heresies*, in Hippolytus's *Reputation of all Heresies*, in Tertullian's *Prescription against Heretics*. It is possible, indeed, to collect from these one or two leading tests of heresy, but no definition is to be found. The common features of heresy are too well known to call for specific enumeration. We can gather from Irenæus that heretics are those who reject Scripture, who refuse to accept the "doctrina tradita," who deny the authority of the clergy who have come in regular succession from the apostles, who keep aloof from the Catholic Church, the sole depositary of apostolic doctrine (*Against Heresies*, in 2-4). Tertullian, in his usual succinct manner, calls every man a heretic who does not at once accept the "Regula Fidei," and he refuses to argue with such a man even though the heretic proceeds to adduce arguments from Scripture. "A controversy over Scripture with heretics can clearly produce no other effect than to help to upset either the stomach or the brain" (*Prescription*, ad Iam, 16). In the Eastern Church, after the period of the oecumenical councils, Tertullian's test was the touchstone of heresy. The church had her rule of faith expanded into the Nicæo-Constantinopolitan creed, with the various explanations added in the symbols of the remaining oecumenical councils, and a heretic was one who denied this creed in whole or in part. In the Western Church, on the other hand, theologians were accustomed to define heresy in a vague way. Thus Jerome calls heresy "perversum dogma," a heretic, with him, is one who interprets Scripture in other fashion than according to the witness of the Spirit of God, and Augustine summarily defines heresy to be the invention or retention of new and false opinions. But whatever the definition, the rough and ready test was always nonconformity to the "formula fidei prescripta ab ecclesia Romana." Instead of definition the Eastern Church simply points to the creed and the oecumenical councils, the Western Church to the rule of faith enjoined by Rome.

These meagre definitions, extracted from the writings of early theologians, all of them going back in the last resort to the recognized creed of the church for the time being, imply, in spite of their vagueness, that there is a certain essential kernel of doctrine in Christianity, which cannot be denied or challenged without involving the destruction of Christianity itself, and they all point the way to a fuller description of what is meant by heresy in the theological sense of the word. Heresy is a doctrine which, with the appearance of Christian doctrine, is really contradictory to the essential nature of Christianity, and, if persisted in, would in the end make Christianity something very different from what it really is. In order, therefore, to say what heresy is, it is necessary to know what the essential nature of Christianity is, and therefore heresy is generally described by reference to the fundamental nature of Christianity, while the real nature of Christian doctrine is commonly brought out by contrasting it with heresy.

When we look at the matter historically we see that Christianity has always taken the shape of a community thinking and acting for the most part together, and that it has always implied a common life, common work, common

ideas. Christianity appears in history as a community whose common work is to confess and to adore God because of what He has done for His people in salvation. This twofold work of confession and worship has manifested itself in a double organization,—an organization of thought and an organization of work,—doctrine and polity. There may be the church without a creed, and the heart-church without the *congregatio*, but that is not the way in which Christianity has taken actual historical shape. It is possible to conceive the entrance of a heterogeneous element into this organization on either side. A heterogeneous element, something really foreign to it, may become organized with the church's doctrine, or may have become incorporated in the church's polity, and whenever this happens there is a doctrine, apparently Christian, which is really subversive of Christianity, there is a polity which, apparently Christian, is really opposed to the real life of the *congregatio*. This possibility is the historical root of the origin both of heresy and of schism, for heresy is just a heterogeneous element imbedded in the organized dogmatic of the church, and schism is a foreign element which has found its way into church polity. This description, however, is somewhat misleading, because it may happen that an element which seems heterogeneous is not really so, but is on the contrary a true part of the organization. Heresy is not only apparently but really foreign to the system in which it has become incorporated. Its nature is different, and its source is different. Men's apparent inconsistency, therefore, does not prove heresy. A doctrine must be seen to be really contradictory to the fundamental facts of Christianity, and to have come from a different source, before it can be called a heresy. It has frequently happened, accordingly, that doctrines have been judged heretical which a better acquaintance with the nature of Christianity would have pronounced orthodox.

Christianity, under the many forms which it assumes, has always implied the reconciliation of God and man through the person and work of Christ. It implies that Jesus Christ the Saviour has so brought it about that He has established a new kingdom of God which will last, in which men have communion with God through His Spirit. Christianity is complete when the kingdom of God is fully established. "Thy kingdom come" is its aspiration. It therefore implies a moral separation between God and man—a separation which is overcome by the work of Christ the Mediator. The idea of reconciliation is the central thing in Christianity, the essential part in its description. God, man unable to approach God until reconciliation has been made, Christ the Mediator who reconciles, and His people brought again into communion with God,—all Christian doctrine rings the changes on these four fundamental ideas. Whatever contradicts or tends to destroy these, or their relations to each other, is incompatible with Christianity. Whenever any of these four ideas—God, man, Christ, and the kingdom of God—no so much as to introduce notions incompatible with the relations in which they stand to each other in Christianity, then heresy enters. Theology therefore (and Protestant theology only carries the idea somewhat further) has usually recognized four kinds of heresy, corresponding to the four fundamental ideas on which Christian doctrine rests. The nature and character of God and of His relation to the universe and to man may be so misused as to make reconciliation an impossible thing, and so also may the nature of Christ, the nature of man, and the nature of the results of Christ's work among men. Hence arise heresies about God, about the person of Christ, about the nature of man, and about the results of Christ's work—all of them being doctrines which are incompatible with the idea of reconciliation.

I Reconciliation implies that man has been separated by sin from God, and that God can overcome this separation. All descriptions of God, of His nature, character, and works, which contradict this fact may give rise to heresies. Thus God cannot overcome the separation if it be impossible for Him to reach Himself beyond Himself in salvation. The nature of the Godhead may be so described as to contradict the idea of reconciliation, as, e.g., in the Arian heresy. Again, all descriptions of God's relations to the universe which imply that the universe and all things are not absolutely dependent on Him, which imply that His gracious purpose can be thwarted, contradict the idea of reconciliation, and so may give rise to heresies, e.g., the Gnostic doctrine that matter is independent of God. Misstatements about God's relation to Himself and about His relation to the universe give rise to two different kinds of heresy.

II Reconciliation implies a real mediator who can accomplish the reconciliation on both its sides, and so heresies may arise about the nature of Christ. The Saviour may be so described that there is no real mediator, and no real reconciliation. These errors may arise in two ways, as out or other side of the mediation is described. The Saviour may be represented so that He has no real relation to God on the one hand or to man on the other. Heresy may be described in such a way that there is no solidarity between Him and God, as, e.g., in the Eutychian heresy, or He may be described in such a way that there is no solidarity between Him and man, as in the Docetic heresy. Misstatements about the relation of Christ to God and the relation of Christ to man give rise to two different kinds of heresy.

III Reconciliation implies that man is so separated from God by sin that there is real need for salvation, and yet not so separated that he cannot be brought into communion with God again, and the nature of man and especially the nature of sin in man may be so described as to set aside these requirements. The fact of sin and its presence in man may be so explained away as to leave little ground for the necessity of reconciliation, e.g., in the Pelagian heresy. Again, on the other hand, the fact and presence of sin may be so described that there is no efficacy in man for salvation, it may be alleged that sin belongs to the essential nature of man and cannot be removed, e.g., in the Neoplatonic heresy. Thus two misstatements about the connection between man and sin give rise to two kinds of heresy.

IV The results of the reconciliation effected by Christ may also be misstatements. The reconciliation between man and God, which is the formal occasion of the reconciliation, was caused by sin, and the distance between God and man is a moral one. It is not such a separation as might arise from the difference between the divine and the human entities, or from the inevitable distance between God and creature. And so reconciliation has for its effect, not mere absorption into God, but the restoration of moral communion between God and His people. The intercourse was broken by sin, and the result of reconciliation must be moral, it must take effect in a change of will, in the creation of a life of new obedience. False ideas arise when this is misrepresented, and these misrepresentations can arise in two ways—when it is said that the new representations can arise in two ways—when it is said that the action of divine grace impregnates the nature in a magical way, instead of taking effect on the will in a moral fashion, e.g., the magical idea of sacramental efficacy, or when it is said that the result of the reconciliation is to restore above the necessity of living a moral life and of conforming to the law of morality, e.g., the Antinomian heresy.

Thus theology finds at least eight separate kinds of heresy, arising from the entrance of foreign elements into the four fundamental ideas of Christianity. All heresies may be reduced to one or other of these eight classes. In point of fact, however, most heresies which have actually arisen cannot be said to belong purely to any one of them. The class only denotes the type, for one error is apt to bring others in its train, and so most heresies are mixed, and do not in all respects conform to their type.

Theologians, however, have not rested content with the mere theoretical or genetic description of heresy and heretics, and have commonly borrowed distinctions first laid down by jurists in canon law to distinguish more narrowly the characteristic marks of heresy. Thus a false doctrine to be a heresy must be an intellectual error, it must be held *voluntarily*, it must contradict a doctrine already defined by the formula of the church, it must be held *pertinaciously*, and the heretic must be professedly *within the church*, but these distinctions belong properly to the legal aspect of heresy, and must be referred to again.

Many theologians, Schleiermacher among others, have

attempted to describe the actual origin of heresies, and a common mode of explanation is as follows. Heresies arise in that province of theology called dogmatic, and commonly appear during the definition of some important part of dogmatic theology. Dogmatic theology is the rationale of the spiritual events and forces which have called Christianity into being. In the attempt made by the church to understand these events and forces which have called it into being, its attention has commonly been confined to the more outstanding portions. The history of dogmatic shows us that from time to time the church has endeavored to master one doctrine, not the whole round of doctrines, it has endeavored to make distinct single points, instead of working at the various relations of all the doctrines to each other. This very natural mode of work has the one disadvantage that it concentrates attention on isolated portions of doctrine rather than on the whole mass, and between the consecutive portions there are gaps. The mind of man, however, like nature, abhors a vacuum, and summarily fills these vacua up with material usually drawn from the prevailing philosophical or scientific theories of the day. These summary explanations or theories may or may not be in accordance with the spirit of Christianity, and when they are not they become a fruitful source of heresies. One of the best illustrations of this is the introduction into theology of the Aristotelian doctrine of *τὸ ἀκρόν*, which gave the church the Pelagian heresy along with some other.

So much for the general theological conception of heresy, of its nature, divisions, and sources, but before proceeding to describe the use of the term in canon law, it should be observed that the theological does not always correspond with the ecclesiastical meaning of the word. It is generally acknowledged that Holy Scripture is the source of doctrine, and that for the due understanding thereof the enlightening guidance of the Holy Spirit is required, though, of course, the precise meaning of this statement varies in different systems of theology. Holy Scripture and the witness of the Spirit of God are thus the touchstone of heresy. In the Roman Catholic and Greek Churches, however, it is held that the enlightening guidance of the Holy Spirit in this respect is restrained within the limits of certain ecclesiastical machinery (the oecumenical council, the pope, *cathedra*, &c.), which are the only channels through which the Spirit comes to the church, and hence the creed of the church rather than Scripture is the real touchstone of heresy. Protestant theologians, on the other hand, do not believe other than the guidance of the Spirit is always present within this ecclesiastical machinery or that it is given in this way only, and so they make a distinction between mere ecclesiastical and real theological heresies. Ecclesiastical heresies arise when a fundamental statement made in the creed or confession is contradicted. But it may happen, since creeds and councils may err, that the error is not in the contradiction but in the creed, and therefore there is always an appeal from the creed to the Scripture. The ecclesiastical idea of heresy has always the theological idea behind it, and may at any time be corrected by it. Roman Catholic and Greek theologians, on the other hand, do not admit any going behind the record, they do not allow any appeal from the creed to Scripture. According to their ideas the creed is the infallible digest of Scripture, and therefore heresy is to be tested by the creed and not by Scripture—that is, the ecclesiastical and theological ideas of heresy are exactly the same.

2 *Heresy according to Canon Law*—Canon law was the ecclesiastical law of medieval Europe, and is still the law of the Roman Catholic Church, and its description of heresy and of heretics is almost more important than the theological in the investigation of the matter from the historical side. Canon law regards heresy

from the practical side of ecclesiastical procedure and legal enactment. Its view is much narrower than the theological, but much more precise. Orthodoxy is the doctrine maintained by the inflexible Roman Church and assented to by all its faithful members; heresy is dissent from the articles of faith established by the Roman pontiffs and by the councils of the Roman Church. Canon law also is mainly concerned with heresy in order to punish it, and therefore is obliged to treat the whole subject with severe legal accuracy of statement. It proceeds from strict definitions. Perhaps the commonest definition is the following:—heresy is "error intellectus voluntarius contra aliquam propositionem catholicam cum pertinaciter assertus ab eo qui baptismum accepit." Jurists are accustomed to expand this general definition in a variety of qualifying statements. (a) All heresy is error, but every error is not a heresy. It is an error according to canon law to take usury, it is heresy to say that to take usury is not a sin, but taking usury is no heresy. If error is intellectual error. It is intellectual error believed to be truth, and that in spite of predominant opinion. Canonists distinguish between members of the Roman Church who refuse, e.g., to accept the "filioque" clause in the creed, and members of the Greek Church who make the same refusal. The refusal is in both cases an error, but it is a heresy only in the Roman Church, for dissent only in this phylum opinion is against the error. (b) An error also only becomes heresy when it is held voluntarily. To be a heretic a man must stick to his error, although he knows that it has been condemned by the church. A heretic not only errs, but knows that he errs, and wishes to err. (c) Not is every voluntary error a heresy, the heretic must contradict a doctrine which has been clearly stated in the creed and has become part of the defined faith of the church. (d) Not is an erroneous opinion voluntarily professed in opposition to the creed of the church heresy, unless the heretic persists in it. Furthermore, all canonists insist, as an essential element in heresy, and unless it is present no process for heresy can legally proceed. (e) And lastly, a heretic must be a member of the church. He must have been baptized. Neither a Jew, a Mahometan, nor a heathen can be a heretic. They may be unbelievers, they may hold erroneous opinions, but their opinions are not heresies.

From the first qualification, that heresy is an intellectual error, canonists deduce the ground of their enactments against the suspicion of heresy and against those suspected. Canon law uniformly proceeds on the idea that heresy is not merely an error but a crime. It is a crime, however, which belongs to the invisible part of man, to his intellect. It is not something done with his hands or his feet which witnesses can see, and they argue that direct proof is therefore almost impossible, and that the commission of the crime must almost always be proved from suspicions. This suspicion of heresy occupies a very large space in the disquisitions of canonists, and the weakness of their position has made them bring in a very great number of reasons which they seem to think strengthen it (see especially Dandinius, *De suspectis de hæresibus*). They carefully define the degrees of suspicion with the conduct appropriate to each: "whom the suspicion is only 'light,' the suspected are simply to be watched, where it is 'vehement,' they are to be denounced, where it is 'violent,' they are to be treated as heretics. Canonists have carefully analysed and arranged what are reasonable grounds of suspicion. Pope Innocent III. declared that to lead a solitary life, to refuse to accommodate one's self to the prevailing manners of society, and to frequent unauthorized religious meetings were abundant grounds of suspicion, while later canonists were accustomed to give lists of deeds which made the道士 suspect.—a priest who did not celebrate mass, a lay-

man who was seen in clerical robes, those who favoured heretics, received them as guests, gave them safe conduct, tolerated them, trusted them, defended them, fought under them, or read their books, were all to be suspect. The canonist rules for suspicion became a sort of inquisitor's *vide mecum*, and when really practised produced a reign of terror.

Since canon law regarded heresy with such horror and detestation, it is not surprising that it gives many directions, which have the force of legal enactments, whereby men may avoid the dangers of heresy. Pope Alexander IV. prohibited laymen from arguing about matters of faith. The council of Toledo (1129), anxious to put down the Albigenses, ordained that every man above fourteen and every woman above twelve years of age should solemnly swear to abjure every heresy and to maintain in its completeness the Catholic faith. Pope Pius IV. ordered the laity to abstain from reading the Scriptures in the vulgar tongue. The promiscuous reading of books was forbidden, and an index of prohibited books believed to be dangerous to faith or morals was formed.

Canon law regards heresy as a crime, and while it recognizes that the power of the church is spiritual, and that the church visits offences with spiritual punishments such as excommunication, it proceeds on the idea that the state should assist the church in suppressing heresy, and visit heretics with civil pains and penalties, including torture and capital punishment, but this side of the history of heresy belongs as much to civil as to canon law. The church, however, did what it could against heretics. The council of Laodicea (can. 6-9) prohibited them from attending service, though from subsequent acts this could not have been enforced. They were not allowed to give evidence in an ecclesiastical court, a father was prohibited from allowing his son or daughter to marry a heretic, social intercourse with them was prohibited, &c.

3 *Heresy according to Civil Law*.—Civil law treats heresy in a still simpler fashion. The legal idea seems to have been that, since the state approved of one creed and gave it public recognition, to profess any other creed was in some sense civil disaffection or a kind of treason, and manifested lack of loyalty. This notion, however, was supplemented by another and much deeper one in the public law of the mediæval empire. According to the ideas of the earlier mediæval jurists, civil government and ecclesiastical government were equally and in the same sense ordinances of God, and this thought found expression in the twin conceptions of world king and world-priest, emperor and pope, who were God's vicars, and ruled in His name over church and state. God was the king of the world, the emperor was His vicar, and treason, therefore, included treason against God, or heresy, as well as treason against the emperor. This idea lingered long, and indeed still lingers, and complicates the simpler civil notion of heresy. For all practical purposes, however, the deeper thought may be discarded. In civil law, heresy is pertinacious dissent from the creed approved of for the time being. For example, the Lutheran creed, the *Confessio Augustana*, was heresy in all parts of Germany up to the peace of Augsburg, when it was recognized as a creed which might be professed. It then became orthodox in the civil sense of the term, in the same way that the Roman Catholic creed was orthodox, while the Calvinist creed, still unrecognized, was heresy.

Civil punishment followed religious offences as early as the time of Constantine, who enacted severe penalties against the Donatists, and ordained that all possessing Arian books should burn them on the pain of death. Laws against the reading of heretical books became very frequent during and after the 4th century. Arcadius made the

reading of books written by the Eunomians a capital offence. Theodosius and Valentinian proscribed the Nestorian books, and Valentinian and Marcian the books of Eutyches and Nestorius. The custom became so common that the condemnation of any heresy by the church was followed by the proscription of the writings of members of the sect. The *Codex Theodosianus*, bk. xvi. tit. 5, "De hæreticis," enumerates a great variety of laws against heresy with penalties more or less severe. They had the practical effect of declaring heretics outlaws, who could not hold offices of dignity or value, receive or bequeath money, enforce contracts, &c. In some cases death was the punishment for heresy. Justinian made it impossible for any heretic to bear witness in the civil courts of the land. This legislation may all be traced back to the action of Theodosius, who imposed the Nicene creed upon all his subjects, and made it a law of the land. It continued in force during the Middle Ages, and in consequence heretics who could not accept the Nicene creed were outlaws also. This perhaps explains the curious fact that almost all the mediæval heretics were also revolutionists. During the Middle Ages, especially from the time of Innocent III. onwards, civil interference in cases of heresy was much increased. In the early church the power of discipline belonged to the presbytery, and was afterwards usurped by the bishops, who continued to exercise it in matters of heresy until Innocent III. appointed the Inquisition to deal with heretics. So long as the empire was not Christian, the civil law had nothing to do with the punishment of erroneous opinions, but as soon as Christianity became the authorised religion of the state, the old pagan idea that the state has power to punish *religiones novæ et illicitas* was revived. The state, either instructed by the church or, as in the Theodosian code, without instruction, visited with civil pains and penalties all such opinions. This came to a height when the Inquisition was established, and civil courts and national assemblies one after another decreed that whatever penalties were imposed by the Inquisition should be imposed by the state, or else awarded over all cases of heresy to the Inquisition to be dealt with as matters deserving the infliction of civil penalties, fines, imprisonment, torture, and death. There is no sadder page in the history of the church than her alliance with the state for the purpose of torturing men out of opinions different from her own. Since the Reformation the persecuting spirit, although tenacious of life, has been gradually dying out.

Principal Heresies.—Early Christian theologians wrote a great many books against heresies in which they enumerated the various heresies which had sprung up in the church up to their own time. St. Augustine tells us (*Ep. 222*) that Philastrius, bishop of Brescia, had discovered 28 heresies among the Jews before the coming of Christ, and 128 in the Christian Church afterwards, and many other orthodox writers have given very long lists of these erroneous opinions. It was natural that the early centuries of the Christian era, especially the first five, should be some what prolific in heresies, because that was the very period when the church was occupied in defining the principal doctrines of Christianity. A history of heresies must spend most time upon the early centuries. The first dogmatic work of the church was to define the nature of Christ, who occupied the central place in its thought, and it had to steer its way between two opposite views, both of which interfered with the full dogmatic expression of the nature of the Mediator. On the one hand, many of the Jewish converts never rose to the height of the Christian idea of the person of Christ, and it is evident that these must have been very numerous from the emphasis with which it is insisted that Christians should *θεολογῶν τὸν υἱόν*. These Jewish converts preferred to regard the Saviour as the last

of the prophets, one who bore the same relation to God and to man as the prophets did. They shrank from the idea of the incarnation, they seemed to feel no need for the divine Saviour. This theory was of course accompanied by other views about the nature of Christianity, but the main element was opposition to the Christian doctrine of the real divinity of Christ, God who has become man. This Ebionite heresy has been maintained by men who wish to call themselves Christians since these early days, and has taken a great variety of shapes, but whether it is held by Jew or Unitarian, there is the same outline of opinion and the same steadfast repugnance to the doctrine of the incarnation. On the other hand, the philosophic doctrine of the repugnance between matter and spirit, the idea, which runs through all Greek philosophy, that matter is the source of evil, induced many of the early Gentile converts to Christianity to think of the incarnation as a metaphor rather than as a fact. Christ, they thought, did not take, but only seemed to take, a human body. These Docetists, as they were called, had a whole series of successors in the early church. When Christian theology advanced step by step in the definition of the doctrine of the person of Christ, it was this old idea of the repugnance between the divine spirit and human nature embodied that lay at the root of the Apollinarian, Eutychian, and Monophysite heresies. Apollinarius denied that the Theanthropos had a "rational" soul, he denied the full humanity of the Saviour. Eutyches denied that the Theanthropos had a human nature, and the Monophysites, in their various theories, held strongly by the same idea. All these theories, however different in form and expression, denied the full and true humanity of Christ, and so contradicted the church's yearning for a Saviour truly man as well as truly God. These heresies, along with the Nestorian, were all finally condemned at the council of Chalcedon (the fourth oecumenical).

But long before the church had definitely set forth the doctrine of the person of Christ, its attention was turned to the doctrine of the essential nature of the Godhead. At first this doctrine was scarcely considered apart from Christology. It is impossible to separate the history of the doctrine of the Trinity from the doctrine of the person of Christ, for long the two separate problems were inextricably mixed. At length it became evident to the mind of the church that there were two doctrines, and Christian theology turned aside to discuss, and if possible settle, the doctrine of the essential nature of the Godhead before it proceeded to exhaust the doctrine of the person of Christ. For the real problem in the Arian controversy was not the divinity of the Mediator, but the nature of God. It did not to be thought of as a Trinity or as a Unity? what is the relation of the Second Person in the Trinity to the First Person? The real gun to the Arian controversy which came from the discussions in the Arian controversy was to thrust out the Greek conception of Deity as the Absolute who cannot be described save by negations, and to put in its stead a Christian conception which shows that there are motions within the Deity which, however incomprehensible, enable us to know that God may be in sympathy with men, and that all things may live, move, and have their being in Him.

The philosophical idea that matter is the source of evil, that matter has always some stubborn element in it by which it can defy the ideal, gave rise to a whole series of ancient and mediæval heresies. The Gnostics in all their various sects distinguished between God and the Creator. The good God, they held, could not defile Himself by contact with matter, and therefore could not be the God of creation and providence. Christian theology, on the other hand, has always confessed God to be the Almighty Maker

of heaven and earth, and all things seen and unseen, and the necessity for such a doctrine of creation consists in the fact that the Christian consciousness demands the absence of any thing that might come in between God and the furtherance of His plan of salvation. It demands that all things be thought of as dependent on God, in order that He may be able to make all things work together for the good of His people, and so it has strenuously asserted the doctrines of creation and providence in opposition to an independent matter and the reign of fate. The Gnostic ideas were repudiated by the Manichaeans and by several medieval sects, such as the Paulicians and Messalians, and, in the Eastern Church, by the Bogomils.

The Pelagian and Manichaean heresies principally concern the Christian doctrine of man and of the presence of sin in man, and contradict the church's creed, because they do away with the Christian doctrine of reconciliation. Pelagianism, it was held, denied the need of God's grace by insisting that man was free from inwelling sin at the beginning of his career, and followed good, when he did follow it, by the power of his own will, while Manichaeism, by asserting that sin belonged to the essential nature of man, seemed to paralyze the whole divine action in reconciliation. It was held by the orthodox opponents of Pelagius that his opinions really implied that there was no real need for the Saviour and the salvation which Christianity describes, and that semi-Pelagianism, although much nearer orthodox doctrine, very inadequately comprehended that sinfulness in man which rendered reconciliation indispensable ere there could be a restoration of communion with God.

The Antinomian and various kinds of mystical theories about the Christian life all proceed upon a view of the effects of Christ's work which is at variance with fundamental Christian ideas. Christian doctrine teaches that men reconciled to God will strive to live a life of new obedience to Him, and it holds that this life of new obedience comes under the same moral laws as the ordinary life of man. But many Christian sects have professed theories about this life of new obedience which seem to imply that it is not under the laws of ordinary morality, that Christian freedom means licence to do what ordinary morals forbid. The Epistles to the Corinthians seem to say that such theories were held in the apostolic church, and were denounced by the apostles, many of the Gnostic and Manichaean sects undoubtedly professed them. The same views occur again and again in medieval heresy, and were held by many of the enthusiastic sectaries in Reformation times and later. The Brethren of the Free Spirit in the 13th and 14th century, the Anabaptists during the Reformation period, and some of the followers of Molinos are examples. The mystical theories, which so largely entered into the medieval church, and which have continually clung to the skirts of Christianity, have in many instances proceeded on the principle that the new life is implanted in man in a physical way, and magical ideas of the means of grace have been very destructive to the moral theory of the Christian life.

The history of the medieval heretical sects is by far too complicated to be entered on here. Many of them did no more than protest against the hierarchical constitution of the church of the Middle Ages. Most of them only sought room to carry out to the full their ideas of a time "Imitatio Christi," but it is also certain that a good many Gnostic and Antinomian tenets were held. The Friends of God, the Fraticelli, the Boghards, were all mystics, but their mysticism was of a very harmless description, while the Brethren of the Common Life were worthy forerunners of the pietists of the 18th century (see MYSTICISM).

The heretics of the Reformation Church scarcely call for separate remark. The Zwickau prophets and the Ana-

baptists held opinions at variance with the ordinary notions of what is meant by the Christian life. Schwenkfeld, the Quietists, the followers of Madame Bourignon, all revived types of mysticism which had appeared long before, and the Quakers had then forerunners in medieval times. Many of these sects, though called heretical, seem to have arisen simply from the desire to live purer and more spiritual lives than the church organization of their times permitted, and in order to do so were led to lay stress upon the idea of personal guidance by the Spirit of God, and on the necessity of the "house and heart church" in opposition to the external church life of their time, on the need of personal as opposed to official religion.

In this article Christian heresy alone has been described. Heresy, however, arises wherever there is doctrine, and there are Mahometan and Buddhist heresies and sects as well as Christian.

The best history of sects and heresies from the sympathetic side is Gottfried Arnold's *Urgeschichte des christlichen und ketzerischen Aberglaubens*, 1698-1700 (best ed. that of Schaffhausen, 1710). A very good list of writers on heresy, ancient and medieval, is given in Burton's *Dictionary of Heresies of the Apostolic Age*, 1829. The various Trinitarian and Christological heresies may be studied in Danica's *History of the Doctrine of the Person of Christ*, 1844-66, Eng. tr. 1851-66, the *History of the Arian Heresy*, 1844-66, the works of Marnet, Matter, and Deussch, the medieval heresies in Hall's *Geschichte des Ketzer- und Waldenserthums*, 1848-60, and Pagnol's *Geschichte des deutschen Aberglaubens*, 1873. Questions in regard to the *Urgeschichte des christlichen und ketzerischen Aberglaubens* in Palmer's *Gemeinschaften und Sekten*, 1875, the Reformation and 17th century heresies and sects in the *Anabaptist tenets of christianism*, Fentzen and Gendreau, East-Trans., 1702 Bohmer's *Jus Ecclesiasticum Protestantium*, 1711-23, and Van Beyer's *Jus Ecclesiasticum*, 1709, detail at great length the relations of heresy to canon and civil law. On the question of the legitimacy of heresy see Smith and Chetwood's *Doct. of Eccl. Antiquity*, 1711-12, and on the right of admission of heretics into the church, compare Mutene, *De Rituibus*, and Molinos, *De Penitentia* (T. II.).

Heresy according to the Law of England.—The highest point reached by the ecclesiastical power in England was in the Act of *Haereticum umbonando* (2 Henry IV. c. 15). Some have supposed that a writ of that name is as old as the common law, but its execution might be questioned by a judge from the crown. The Act of Henry IV. enabled the diocesan alone, without the cooperation of a synod, to pronounce sentences of heresy, and required the sheriff to execute it by burning the offender, without waiting for the consent of the crown. A large number of penal statutes was enacted in the following reign, and the statute 1 Eliz. c. 1 is regarded by lawyers as limiting for the first time the description of heresy to tenets declared heretical either by the canonical Scriptures or by the laws then generally received as such as national laws, so declared by parliament with the assent of convocation. The writ was abolished by 29 Car. II. c. 9, which reserved to the ecclesiastical courts their jurisdiction in cases of heresy and other offences, and their power of awarding punishments not extending to death. Heresy became henceforward a purely ecclesiastical offence, although disturbing laws of various kinds continued to be enforced against Jews, Catholics, and other dissenters. The temporal courts have no knowledge of any offence known as heresy, although incidentally (e.g., in questions of copyright) they have refused protection to persons promulgating religious or blasphemous opinions. As an ecclesiastical offence it would at the present moment be almost impossible to say what opinion, in the case of a layman at least, would be deemed heretical. Apparently, if a proposition could be made out, an ecclesiastical court might still sentence a layman to excommunication for heresy, but by no other means could his opinions be brought under censure. The last case on the subject (Jenkins v. Cook, *Law Reports*, 1 Probate Division 89) leaves the matter in the same unsatisfactory position, as a clergyman refused the communion to a parishioner who denied the personality of the devil. The judicial committee held that the rights of the parishioners are expressly defined in the statute of 1 Edw. VI. c. 12, and without admitting the error of the church, which is not binding on the laity, could specify a lawful cause for rejection, held that no lawful cause within the meaning of either the canons or the rubric had been shown. It was maintained at the bar that the denial of the most fundamental doctrines of Christianity would not be a lawful cause for such rejection, but the judgment only queries whether a denial of the personality of

² Stephen's *Co. mundaum*, lib. IV. c. 7.

HERISAU, the largest town in the Swiss half-canton of Appenzell auser-Rhoden, is situated at the confluence of the Glatt and Dülhbach, 7 miles north-west of Appenzell, and about 2550 feet above sea level. The town is irregularly built, and extends over a large area. The church-tower, in which the archives are kept, is referred to the 7th century. Herisau has a public library, an arsenal, a new town-house, and a hospital, and is the seat of the cantonal council and of a district court of justice. The manufactures comprise muslin, cotton, and silk. Christianity was introduced at Herisau (a name during the Middle Ages Latinized as Angia Domini) about the beginning of the 7th century. The nobles of Herisau were its first superiors, but their power passed in 1390 into the hands of the abbots of St Gall, from whose somewhat oppressive rule the people bought themselves free in 1403. The population in 1870 was 9736. In the neighbourhood beautiful walks lead to the interesting ruins of the castles of Rosenberg and Rosenberg. The baths and goats'-wey cure of Homischbad are about 1 mile to the north-east.

HERISTAL. See HERISTAL.

HERITABLE JURISDICTIONS, in the law of Scotland, were grants of jurisdiction made to a man and his heirs. They were a usual accompaniment to feudal tenures, and the power which they conferred on great families, being recognized as a source of danger to the state, led to frequent attempts being made by statute to restrict them, both before and after the Union. They were all abolished by the Act 20 Geo. II. c. 43, which enacts (§ 1) that all heritable jurisdictions of justiciary, and all regalities and heritable bailiwick, and all heritable constabularies, other than the office of high constable of Scotland, and all stewardships, being parts only of shires and counties, and all sheriffships and deputy sheriffships of districts, being parts only of shires and counties, belonging to or possessed by any subject or subjects, shall be taken away and totally dissolved and extinguished. At the same time, constabularies and other jurisdictions having been recognized as rights of property by the Treaty of Union, the Act provides that compensation shall be awarded to all persons lawfully possessed of such jurisdictions, and the sum of £150,000 was afterwards voted by parliament to pay the claims for compensation for loss of jurisdiction, as settled by a report of the Court of Session (see *Erskine's Institutes*, by Nicholson, p. 92).

HERLEN, FRITZ, of Nördlingen, was an artist of the early Swabian school, who tempered the rudeness of his native art with some of the delicacy of the masters of Bruges. The date and place of his birth are unknown, but his name is on the roll of the tax-gatherers of Ulm in 1410, and in 1467 he was made citizen and town painter at Nördlingen, "because of his acquaintance with Flemish methods of painting." One of the first of his acknowledged productions is a shrine on one of the altars of the church of Rothenburg on the Tauber, the wings of which were finished in 1466, with seven scenes from the lives of Christ and the Virgin Mary. In the town-hall of Rothenburg is a Madonna and St Catherine of 1467, and in the choir of Nördlingen cathedral a triptych of 1488, representing the Nativity and Christ amidst the Doctors, at the side of a votive Madonna attended by St Joseph and St Margaret as patrons of a family. In each of these works the painter's name certifies the picture, and the manner is truly that of an artist "acquainted with Flemish methods." We are not told under whom Herlen laboured in the Netherlands, but he probably took the same course as Schongauer and Hans Holbein the elder, who studied in the school of Van der Weyden. His altarpiece at Rothenburg contains groups and figures, as well as forms of action and drapery, which seem copied from those of Van der

Weyden's or Memling's disciples, and the votive Madonna of 1488, whilst characterized by similar features, only displays such further changes as may be accounted for by the master's constant later contact with contemporaries in Swabia. Herlen had none of the genius of Schongauer. He failed to acquire the delicacy even of the second-rate men who handed down to Matsys the traditions of the 15th century, but his example was certainly favourable to the development of art in Swabia. By general consent critics have assigned to him a large altarpiece, with scenes from the gospels and figures of St Florian and St Florentia, and a Crucifixion, the principal figure of which is carved in high relief on the surface of a large panel in the church of Dinkelsbühl. A Crucifixion, with eight scenes from the New Testament, is shown as his in the cathedral at Christ in Judgment, with Mary and John, and the Resurrection of Souls in the town hall of Nördlingen. A small Epiphany, once in the convent of the Minorites of Ulm, is in the Holzschnitz collection at Augsburg; a Madonna and Child in the National Museum at Munich. Herlen's epitaph, preserved by Rathgeber, states that he died on the 12th of October 1491, and was buried at Nördlingen.

HERMANN, the popular modern name in Germany for the ancient German hero Alaminus. See GERMANY, vol. x p. 476.

HERMANN, commonly distinguished as Hermann Contractus, or Hermann von Hermsdorf, an old German chronicler and scholar, was born in 1018, a son of the Swabian Count Wolrad (Volpert) of Veltheimingen (Vellingon or Vörlingen), and died in 1054, at the family residence of Alshausen near Biberach. Educated at the monastery of Reichenau, and afterwards admitted a member of the fraternity, he added greatly to that reputation for learning which the establishment had maintained from the time of Abbot Beato. Besides the ordinary studies of the monastic scholar, he devoted himself to mathematics, astronomy, and music, and constructed watches and instruments of various kinds.

His chief work is a *Chronicon ab his conditis ad annum 1054*, which in its earlier portion consists of a compilation from previous chronicles, but between 1044 and 1054 furnishes important and original material for the history of Henry III. The first edition, from a MS no longer extant, was printed by Elshard at Basel in 1529, and reissued in 1630; another edition appeared at St Blasien in 1690 under the supervision of Usenermann, and a third, from a Rastachian MS, forms part of vol. v of Pertz's *Monumenta Germaniae Historica*. A German translation of the last is contained in *Volke's Die Geschichtschreiber des deutschen Volkes*. The separate lives of Conrad II and Henry III, often ascribed to Hermann, appear to have passed through his hands. *De mensura rationabilis* and *De utilitate excolendi* (to be found on the authority of Schilling MSS, in Pertz, *Thesaurus anecdotorum novissimus*, in) being the first contributions of moment furnished by a European to this subject, Hermann was for a time considered the inventor of the extolable. A didactic poem from his pen, *De arte vitæ per seipsum*, is printed in Haupt's *Brüche von des deutschen Alterthum* (vol. viii), and he is sometimes credited with the composition of the Latin hymns *Veni Sanctus Spiritus*, *Salue Regina*, and *Agnus Dei*.

HERMANN, FRIEDRICH BENEDICT WILLHELM VON (1795–1868), one of the most distinguished of modern writers on political economy, was born on 6th December 1795, at Dinkelsbühl in Bavaria. After finishing his primary education he was for some time employed in a draughtsman's office. He then resumed his studies, partly at the gymnasium in his native town, partly at the universities of Erlangen and Würzburg. His attention seems principally to have been given to mathematics and political economy. In 1817 he took up a private school at Nuremberg, where he remained for four years. After filling an appointment as teacher of mathematics at the gymnasium of Erlangen, he became in 1823 privat-docent at the university in that town. His inaugural dissertation was on the notions of political economy among the Romans (*Disserta-*

supper-tables, and from insurance for risk. The ninth and tenth essays, on "Revenue" and "Consumption," are perhaps especially interesting from the clear mode in which the theory, afterwards called that of the wages fund, is rejected, and from the precision with which the various points of view for estimating net revenue are discriminated.

This brief analysis is sufficient to show the high value of Heilmann's work as a contribution to pure economics. On practical questions, those of economic legislation, his opinions are only to be gathered with difficulty from the papers in the *Gesichte des Gewerks*, and generally well expressed with such reference to special circumstances as to render doubtful their full import. It seems probable, however, that his views on production were far from clear, and that he was somewhat under the sway of the dangerous principle that the best financial policy is unconcerned of national industry. It is difficult, however, to say so directly on this subject.

See Heilmann's *Abhandlung über Nationalökonomie*, pp. 622-28. Heilmann, *Archiv für Politik und Rechtswissenschaft*, pp. 400-79. (Alt 181)

HEIMANN, JOHANN GOTTFRIED JAKOB (1773-1848), classical scholar and philologist, was born at Leipzig on November 23, 1772. Entering the university of his native city at the precocious age of fourteen, Heimann at first studied law, but his inclination to classical learning was too strong to be resisted, and accordingly, after a season spent at Jena in 1793-94, he became a lecturer on classical literature in Leipzig. In 1798 he was appointed professor extraordinarius of philosophy at the university there, and after refusing an invitation to proceed to Kiel as rector of a school, he was in 1803 chosen professor of eloquence. In 1809 he received the chair of poetry in addition. He died, senior of the university, on December 31, 1848.

Heilmann devoted his only attention to the classical poetical metres, and published on this subject *De metris Græcorum et Romanorum poetarum*, in 1796, *Handbuch des Metrik*, in 1798, *Über in metrische metrische*, in 1816, of which an *Expositio* appeared in 1818, and *De Metris Poetarum*, in 1817, attached to Heyne's edition of this author. Of his numerous and valuable writings on Greek metrics the chief are *De numerandi ratione Græcorum grammaticorum*, 1801, *Notæ et Brevia notæ*, in 1816, *De prosodia Græcorum poetarum*, 1808, and *De prosodia Græcorum poetarum*, 1811. His *Lectiones de Poetis* appeared in 1808. His edition of the classical commentaries of the plays of Euripides (see vol. viii p. 680), the *Orchestra Aristophanis*, 1799, *Tragicorum de Plantis*, 1800, *Factus Aristidis*, 1804, *Hymni de Ovidio*, 1806, and the *Homæi Hymni*, 1810. In 1826 Heimann finished the edition of Sophocles begun by Ewald. His editions of Bion and Moschus were published posthumously in 1849, and of all the plays of Æschylus in 1852. The *Oxyrhynchus*, a collection of Heilmann's smaller writings in Leipzig, appeared in seven volumes between 1827 and 1877.

HEIMANN, KARL FRIEDRICH (1801-1860), one of the leading representatives of classical investigation in Germany, was born August 4, 1804, at Plankfort-on-the-Main. His early education was received partly at Plankfort and partly at Weilburg, and his university studies were carried on at Heidelberg and Leipzig. On his return from a tour in Italy he habilitated in 1826 as privat-docent in Heidelberg, in 1832 he was called to Marburg as professor ordinarius of classical literature, and in 1842 he was transferred to Göttingen to fill the chair left vacant by the death of Otfried Müller. Both at Marburg and Göttingen he likewise held the office of director of the philological seminary. He died at Göttingen on the 8th of January 1860. Heimann's scholarship took in a wide and even widening horizon, but his vision was clear and steady, and he knew well how to portray for other eyes the scenes that shaped themselves with new life before his own. Among his more important publications are the *Lehrbuch der griechischen Antiquitäten*, of which the first portion (Heidelberg, 1841) deals with political, the second (1846) with religious, and the third (1892) with domestic antiquities, the *Geschichte und System des Platonischen Philosophies* (Heidelberg, 1839), an edition of the *Platonische Dialoge* (9 vols., Leipzig, 1861-62), and *Classische Werke des griechischen und römischen Alterthums*, 1857-58, 2 vols., published after his death by G. Schmidt. A collection of *Abhandlungen und Beiträge zur class. Alterthumskunde* appeared in 1849, but the great mass of his essays and brochures,

which deal with a vast variety of a chronological, a static, critical, and philosophical subjects, are still unarranged. See Lesclapart, *Zur Erinnerung an K. F. Heimann* (Berlin, 1861).

HEIMANNSTADT (Hungarian, *Nagy-Szeben*, Latin *Cibinium*), chief town of an Hungarian county of the same name, is advantageously situated on the Sebeu, an affluent of the Aluta, about 72 miles S.E. of Kolozsvár (Klausenburg), and is the terminus of the Kapus and Nagy-Sebeu branch line of railway, in 46° 48' N. lat. and 24° 9' E. long. It is the see of a Greek Orthodox bishop, the meeting place of the Lutheran consistory for the Transylvanian circle, and the headquarters both of the honvéd (or "defence militia") and of the regular infantry and artillery of the district, and it also possesses royal courts of law and assizes, and offices of finance, assay, state survey, and engineering. Heimannstadt has a somewhat mediæval appearance, the streets being often narrow, and the houses built in the old German style. Of the squares the most striking is the large quadrangular market-place. The public buildings comprise Roman and Greek Catholic, Greek Orthodox, Calvinist, and Lutheran churches, a royal law academy, both Roman Catholic and Lutheran gymnasiums, a Greek Orthodox seminary for priests, a hospital for the insane, foundling and orphan homes, Franciscan and Ursuline convents, a house of correction, civil and military hospitals, county and town halls, the university and large new artillery barracks, the town theatre, the "Transylvanian assistance office," the "Alanna" bank, and, above all, the Bruckenthal palace with its fine museum and library. Among the industrial establishments are factories for the preparation of soap, candles, soda, sulphuric acid, bone-dust, paper, cloth, linen, leather, caps, boots, combs, and building materials. There are also printing houses, tanneries, and rope walks, several distilleries, and a large brewery. A brisk trade is carried on both at the regular weekly markets and at the special fairs. The civil population in 1870 was 18,995, of whom about two-thirds were of German (Saxon) and the remainder of Hungarian and Magyar extraction.

The German name of the town is traced to Heimann, a citizen of Nuremberg, who about the middle of the 12th century established a colony on the spot. In the 13th century it bore the name of *Villa Heimmanni*. Under the last monarchs of the native Magyar dynasty Heimannstadt enjoyed exceptional privileges, and soon became a thriving centre of trade, its commerce with the East rising to considerable importance. In the course of the 15th and 16th centuries it was several times besieged by the Turks. In 1610 it suffered at the hands of the Transylvanian prince Gabriel Bethlen. At the beginning of 1849 it was the scene of several engagements between the Austrians and Hungarians, and later in the year it was several times taken and retaken by the Russians and Hungarians, the latter being eventually forced to yield to overwhelming numbers, August 6.

HERMAS. See APOCALYPTIC FATHERS, vol. ii p. 197. HERMENEUTICS, BIBLICAL, is that branch of theological science which treats of the principles of Scripture interpretation. Various descriptions of the theory of the discovery and communication of the thoughts of Holy Scripture (Lange), the science of attaining clearness both in comprehending and in explaining the sense of the Biblical authors (Ernesti), the methodological preparation for the interpreter and for exegesis (Doedes), the science of the removal of differences between us and the sacred writers (Immer), it has for its task to determine the laws of valid exegetical practice. Schleiermacher and Klausen have limited it to the doctrine of what the interpreter has to observe in order to put himself in possession of the mind of Scripture. The former defines it as a discipline which looks simply to the reader's own apprehension, not to the conveyance of the meaning ascertained to others, which latter is to be regarded, he thinks, as but a particular division of the art of speaking and writing. It has been

generally taken, however, to have respect to the communication as well as the acquisition of the thoughts of the Biblical writers. This large definition, which is as ancient at least as Augustine's statement of the two things, "quibus utitur, omnis tractatio Scripturæ, modus invenienti quæ intelligenda sunt et modus proferendi quæ intellecta sunt" (*De Doct. Christ.*, i, 1), has been formally accepted or practically acted on by most modern authorities. It is consonant with the currency of the terms *ἐρμηνεία*, *ἐρμηνεύω*, *ἐρμηνεύω* (connected it may be with *ἑρμεν*, but not derived from that, such use of a deity's name being probably unexampled).¹ These in the classics express both expounding (Pindar, *O.*, 2, 153) and interpreting or translating a foreign language to others (Xen., *Anab.*, i, 2, 17, Herod., i, 126), while in the New Testament *ἐρμηνεύω* means to translate (John i, 39, 43) and *ἐρμηνεύω* to expound, interpret, or translate (Luke xxiv, 27, i Cor. xii, 30, Acts iv, 38). The definition is in harmony too with the Protestant idea of exegesis as an art which brings the contents of Scripture to the general understanding, and the Protestant conception of the direct approach of God's word to man's heart by Scripture. As the theory of the interpretative art hermeneutics is usually taken to be an historical science, forming a subdivision of historical theology. Where, however, a fruitful, instead of a threefold, distribution of theological science is adopted, it is assigned to literary theology. It presupposes such disciplines as textual criticism and Biblical introduction, while it may exercise a reflex influence on some of the discussions with which these are conversant. Although practice precedes theory, and only through the use of the art of interpretation can the principles of interpretation be reached, as it is out of Scripture itself that the laws of Scriptural exegesis must be drawn, theoretically this science proceeds exegesis and forms an indispensable preparation for Biblical theology. Much which it has been the custom to embrace within it belongs really to general hermeneutics. The limits properly assignable to it are comparatively narrow, its immediate object being to decide how the laws of general hermeneutics as related to the particular records known as Scripture. The propriety of a special Biblical hermeneutic is established so far as Scripture is proved to be more than an ordinary literature. The Christian who comes to the Bible with the conviction that it is the record of divine communications, and with the experience that it is the medium through which God has spoken to him and led him into new relations to Himself, has to ask whether the principles of ordinary hermeneutics have to be modified or supplemented when applied to these books. Neither the Christian recognition of the spiritual character of Scripture nor the Protestant assertion of the right of private judgment, the prepossession of Scripture, and the laity's direct interest in the Bible, warrants the extreme position assumed among some sects, that a scholarly interpretation and, therefore, a science of hermeneutics are superfluous. Being a literary record composed in languages which demand the exegetical *modus* of translation, and produced under circumstances, by writers, and for readers widely removed in date and character from our present acquaintance, Scripture requires a scientific process for its exposition, and the laws of that process must be verified. The peculiar value which attaches to it as a holy literature makes this its more useful, the exceptional position assigned it rendering its interpretation open to the invasion of prepossession and private religious ideas. The exclusive authority ascribed to these books by the Protestant, who accepts them as the only rule of faith and life, gives him a special interest in hermeneutics. The concrete and historical form in which their spiritual teaching appears, the figurative, typical, and symbolical terms

so largely used in them, the numerous presuppositions on which their statements of religious truth and fact proceed, suggest the necessity of such a discipline. The qualities of Scripture which render its appeal to the common understanding distinct and immediate are arguments for scientific intelligence in edifying from its declarations nothing more and nothing less than their exact intention. The interpreter's function being, not to develop some meaning which the words might bear to present students or which the first readers may have seen in them, but simply to ascertain with precision and completeness the ideas which the writers themselves meant to convey, it may be said with Schleiermacher that in a certain sense the interpreter has to edify more than the author introduced. The former has to bring out into clearness much that influenced the latter half-unconsciously in his composition, and to give objective expression to much that underlies his definite statements. Hence the special need for a scientific hermeneutic in the case of a book like the Bible, in which there is so much that is implicit. The vast variety of results reached in crucial passages, and the wide diversities of method which have been pursued among individual exegeses and in exegetical schools, make the propriety and utility of such a science the more apparent.

Since Christophori Völke (*Hermeneutica Novi Testamenti ac annotationes dogmaticæ et historicæ philologicæ per p. in. caspari corradum erasmum omnia in theologia Christiana præsentantibus auctoribus*, Lipsiæ, 1736) the hermeneutics of the New Testament, for the sake of convenience or on grounds of scientific distinction, has often been separated from the hermeneutics of the Old Testament. The scientific union or dyjunction of these disciplines depends on the view entertained of the mutual relations of the Hebrew Scriptures and the Christian. Where the Bible is seen to constitute an organic whole, the hermeneutical principles applicable to the two Testaments are treated in connexion. It then becomes one great object of the science to grasp the differences which are discovered within the unity of Scripture, and exhibit what account is to be taken of these in the art of interpretation. A distinct position, however, naturally belongs to Jewish hermeneutics, which dealt with the Hebrew Scriptures as at once the entire written revelation of God, and the repository of the highest wisdom on all subjects of human inquiry. The results of the scientific study of the Old Testament, which was carried on with vast activity from Ezra's time by numerous scribes and in great schools and colleges (Jerusalem, Tiberias, Sura, Pumbeditha, Nehardea, &c.), are seen in the Talmudical writings, the *Mishna* giving authoritative enlargements and explanations of the law, and the *Gemara*, in its twofold form of *Tiberian* and *Babylonian* Talmud edited at Tiberias, and *Babylonian* Talmud proceeding from Sura, containing further commentaries, fantastic definitions, and explanations of prior explanations (see TALMUD). The most ancient Jewish interpretation of Scripture, the *Mishna* ("study," "investigation"), which assumed a fixed character during the period of the second temple and gradually formed a literature, ran out into two great branches, logical or legal exposition, and practical or homiletical exposition. The former, designated "*Halakha*" ("rule by which to walk," "binding precept"), brought the law to bear upon points of religious or general interest on which there was no explicit declaration. It confined itself chiefly to the Pentateuch, extracting from it by numerous exegetical expedients a body of "*Halakhoth*" or *sopheric* precepts (*cf.* Matt. vi, 2, Mark vi, 3), which were held authoritative. These, after a long period of oral transmission, gradually assumed written form, and passed finally through a process of compilation, classification, and redaction which extended perhaps from about two centuries before to two centuries after Christ. The latter,

¹ See article *ἑρμηνεία*, and compare Curtius, *Greek Etymology*, § 860.

styled "Hagada" ("opinion," "free exposition"), was meant for edification, traversed the entire Old Testament, and occupied itself with the application of Scripture to the purposes of practical instruction in all manner of subjects, ethical, political, metaphysical, theosophic, as well as religious. Its expositions were conveyed in forms, symbolical, poetic, parabolic, such as were most likely to attract attention, and, though of no binding authority, it made itself so attractive to the people that it was often known as "the Mishnah" distinctively. The hermeneutical laws followed in these two lines of exposition are sufficiently well known. Elazar ben Jose, the Galilee, a distinguished rabbi of the 3d century of our era, has embodied the results of a final reduction of the principles of the Hagadic exegesis in a series of thirty-two rules. Some of these are somewhat long, e.g., with the use of brachylogy, repetition, parallelism, the reconciliation of two discrepant texts by a third, &c. Many of them are wholly fantastic, prescribing how explanations are to be sought by reading the letters of a word to their numerical value, by the transposition of letters, by the substitution of another word of the same numerical value for one which yields no worthy sense, by studying the introduction of superfluous particles, &c. Such principles held a much smaller place in the Halahic exegesis, which, as it aimed at something higher than applications of Scripture, could only find a few seductions in certain directions, so far as it was true to its ideal. In the field of the Halahic hermeneutics Hilul I. (chad 8 or 10 a.p.) occupies a conspicuous place. He reduced the traditional legal tradition of the Jews, with its bewildering multiplicity of laws, from the 600 or 700 sections over which it is said previously to have spread, to six capital "Sedarim" or orders, forming a manageable basis on which his successors 'Akiba, Simon III., and Jehoshua I. could work on to the final codification of the *Mishnah*. He was also the first to formulate definite rules by which the rabbinical development of the law should proceed. These canons of interpretation were seven in number, afterwards increased by Rabbi Ismael to thirteen by the addition of seven new rules and the omission of the sixth, and looked to the construction of Biblical warrant for precepts which it was wished to prove implicit in the law. These "Midloth" were instructions to reason (1) *a minori ad maius*, (2) *ex analogia*, (3) by derivation of a principal proposition from a single passage, (4) by derivation of a principal proposition from two passages, (5) by limitation of the general through the particular, (6) by explanation of one passage through another, (7) by the use of the context. The idea that the Old Testament, pre-eminently the law, held hidden in it the highest wisdom on all subjects, was naturally inimical to the rights of the literal sense. The rabbinical hermeneutics drew inevitable distinctions between the *playa* or unadorned sense (*pasuk*), which again was described as either verbal (*shema*) or figurative (*chok*), and the derivative or studied sense (*derash*, *shema*), which was to be sought either by inference (*shema*) or by artificial conjunction (*shema*). The natural sense, however, though practically robbed of its dues, was not positively ignored. This regard for it, which was never wholly disowned, ultimately took shape in the improved rabbinical hermeneutics of the Middle Ages. In the writings of such rabbis as Sandas Gaon, Jaichu, Rashi, Kimchi, Maimonides, Abarbanel (a line of expositors extending from the 10th to the 16th century), we find, alongside the traditional rules and explanations, a scientific recognition of the interpreter's duty to give the literal sense as well as a practical application of the principles of grammatical and historical exegesis to the Old Testament.

The hermeneutics developed among the Hellenistic Jews had marked characteristics of its own. These interpreters, departing from the exclusiveness of rabbinical devotion to

the Old Testament revelation, and from the pure Hebraism of native Jews, brought to the study of the sacred books a range of ideas derived from Hellenic culture. They had to devise a hermeneutical procedure which would harmonize their new ethnic learning with the traditional estimates of the Jewish Scriptures. To the theosophic Hellenist, and especially to the Alexandrian Jew, acceptance of the plain sense was often an impossibility. A reconciliation was sought by the use of allegorical interpretation. This method was also pursued by the Rabbinical exegesis. It is embraced in the Halahic hermeneutics, and is seen in the distinctions drawn by Palestinian Jews between the body and the soul of texts. But while the allegorical interpretation of native Jews, in consonance with their peculiar estimate of the Hebrew revelation, moved in the direction of the typical, that of the Hellenists became rather mystical. The corporeus in this hermeneutical practice was Philo (born perhaps about 30 a.p.), although he had predecessors in Antiochus, pseudo-Josephus, and others. He devoted himself mainly to the exposition to the Pentateuch, with the view of explaining the realism and anthropomorphism of the Old Testament in a way to suit the philosophy of the time. Wishful to retain the Alexandrian Jew's regard for Moses as the supremely inspired prophet of God and the oracle of all mysteries along with adherence to the current Platonism and theosophy, he supposed that the Hebrew writings contained a twofold mode of teaching, a popular representation of God and divine things, and a spiritual. It was the task of wisdom to penetrate through the envelope of the literal history to the secret sense which it shielded. The verbal sense was acknowledged, but held to be for the ultimate. The outstanding facts in the records of the creation, the deluge, the careers of the patriarchs and Moses, were accepted in an historic sense, but the details of all these narratives were spiritualized. Sometimes the figurative meaning was made the only meaning, but in other cases the objective meaning was allowed to be the intended meaning. The hermeneutical rule, however, was to use by allegory from the superficial anthropomorphic sense (*ro phanaios*) to the higher or spiritual sense (*ro pneumatikos*). The simple histories were symbols of abstract truths. To the enlightened they were so many modes of soul (*epistolai psychas*)—Adam the figure of the sensitive nature, Rebecca of patience, Leah of despised virtue, Egypt an emblem of the Judea, and Canaan of piety.

Two later chapters in the history of Jewish hermeneutics deserve notice. On the one hand the rabbinical procedure was decisively depaupered from by the Kairites, among whom Japhet ben Heli, of Bussoiah, belonging to the close of the 10th century, and Aaron ben Joseph, of the 13th century, are notable. In their case interpretation again sought the *ex media* between bald literalism and arbitrary spiritualizing. It was presented on the principles of renouncing the quest after a variety of senses, abiding by the natural sense, accepting metaphor where the figurative was intended, and conserving the religious interest. On the other hand an extraordinary development was given to the rabbinical hermeneutics by the Kabbalists of the Middle Ages, who used the devices of artificial interpretation in order to find an Old Testament basis for their mixed Neo-Platonist, Gnostic, and Sabaean culture. The Kabbala ("what has been received," "tradition," see KABBALA) had its roots in the ancient doctrine of numbers, for which the Jews were probably indebted to the Chaldeans. The use of the numerical power of letters as a key to mysteries, which the Palestinian Jews had early favoured and which formed a not inconsiderable element in the Hagadic exposition, expanded into a vast system of fantastic Hebrew Gnosticism in the 8th century of the Christian era. The written Word was regarded as a depository of secret doctrine

and absolute truth which could be entered only by the initiated. The mysteries hidden in its letters acquired for their discovery processes of exchange, more or less intricate, between literal and numerical values. By the combinations and permutations of letters, the interchanges of words of equal numerical value, and similar artifices, new meanings were extracted where the proper sense seemed poor, and acceptable meanings found where offence was felt. While the text, *eg.*, states (Numbers vii 1) that Moses married an Ethiopian woman, the veiled sense was shown to be that he married a woman of *beautiful countenance*, and the offence against the law was thus removed. For the letters of לוישׁל added together make the sum 736, the letters in the expression $\text{לוישׁל מר$, "beautiful of countenance," yield the same sum, and the enlightened are able to read the latter idea in the former appellative. Distinct titles came to be applied to different branches of the art. The process of reaching hidden truths by the numerical equivalence of letters (as when from the circumstance that occurs six times in the first and last verses of the Old Testament it is inferred that the world is to last 6000 years) was styled "Gomatrik." The process of forming new words out of the several letters of some solemn term, or one new word by combining the first letters of several words (as when the answer מלך , "enunciation," is discovered in the question in Deut xxx 12, "Who shall go up for us to heaven?") by bringing together the letters with which the several words in the query commence, was called "Notarikon." The use of the anagram or permutation (as when by transposition of למישׁל into למישׁל it is ascertained that "mine angel" of Exod xxii 23 was the angel Michael) was known as "Temulah." The hermeneutical practice of the Kabbalists increased in subtlety as the theosophic system itself grew. Rules were elaborated for exchanging the powers of letters, reading them in a variety of orders, and otherwise conjuring with the literal sense.

The course which Biblical hermeneutics has run outside the purely Jewish pale has been not less changeful or remarkable. The New Testament writings show at large how the apostles and first followers of Christ viewed, interpreted, and quoted the Old Testament. They give little in the shape of formal hermeneutical principles, but allow much to be inferred from usage and example. Conclusions as to authoritative canons of interpretation, so far as these are drawn from New Testament employments of Old Testament Scripture, are weighted with the question whether or how far currency is followed. It is affirmed on the one hand that Paul, *eg.*, in his hermeneutics, was a pure rabbinist, while on the other the equally extreme position is held that his training, in no way reflected in his use of the Hebrew Scriptures. The question of the Old Testament in the New, which forms a question by itself and one of great intensity, takes a variety of modes. Passages are reproduced as direct prophecies of the Messiah and His kingdom (Acts ii 34, Heb i 13), as mediate references to the same through partial realizations of their idea (Heb ii 6-9, 12, 13), as illustrations or applications of principles common to both economies (Rom x 6-8, 1 Tim v 18), as apt expressions, without the character of explicit quotation, in which New Testament statements naturally embody themselves (1 Pet i 24). The proper and immediate sense is adhered to. The application of typology and symbolism (Heb vii 5, ix 6) is at the same time exemplified, and the existence of secondary or higher meanings in allegorical or other forms (Gal iv 24, Eph v 32) is to a certain extent recognized. The typical relation of the Old Testament to the New is everywhere presented. It is exhibited both in the histories and in the institutions, and is developed alike in ethical, didactic, and prophetic significance (1 Cor x 6, 11, Rom vi 17, v

14). The Hebrew revelation is interpreted as a divine preparation for the Christian and as a continuous prophecy bearing onwards towards Christ (Acts ii 25). Its official personages and its saints, its ordinances and its events, are real though imperfect exhibitions of Messiah and the Messianic kingdom. Even its minor occurrences and incidental utterances are anticipations or expressions of the purposes of Jehovah realized in the Christian dispensation (Matt ii 15, Heb iv 7, Eph iv 8-12). How far Biblical hermeneutics within the Christian Church has gathered its principles from Scripture itself, and what use it has made of the New Testament *paris* will appear from its history. It will be enough here to deal with the capital ideas which the various conflicting methods seem capable of being reduced. We indicate which of these prevailed on the whole in important schools and periods, without attempting a chronological statement or detailing the exact relations of each great name to this subject. It is not to be supposed, however, that any single mode was exclusively dominant at any one time, or that the interpreters whose names are connected with some particular procedure held by that only. On the contrary, in the long continued absence of a definite settlement of principles the best writers avowed remarkably from method to method, and men who are largely identified with various modes exhibit at the same time admirable samples of the opposite. It may be said that such a hermeneutical tendency has been followed. These may be conveniently designated the subjective, the dependent, the historical.

I. The first, which we have distinguished as the *Subjective* tendency, embraces all those widely diverse schemes which agree in passing beyond the objective intention of the words and seeking veiled or underlying meanings. To this belong the different forms of the allegorical method, by which is meant the imposition of a sense not designed by the writer. It is the adding of a meaning foreign to the intention, rather than the substitution of an improper for the proper sense. The first Christian interpreters were under special temptations in this direction. The idea of the need of exceptional principles of exposition in order to reach the deep significance of divine communications had a great hold in the ancient mind, Greek, Roman, Oriental, and Hebrew. The spell of this idea and the powerful influence of the Rabbinical tradition, acting on the Christian conviction that the Bible is a divine message, readily induced the notion that the ordinary laws of interpretation are inadequate, and that Scripture is honoured when the natural or "lower" sense is made the stepping-stone to a "higher" sense for which special processes are required. Early Christian literature, although its mysticism may sometimes be otherwise explained, adheres dogmatically to this idea. The apostolic fathers and the Apologists, while not entire strangers to sound spiritual interpretation, are addicted to the allegorical. The *Epistle of Barnabas* endorses faith and perfects *visions* by spiritualizing the details of such narratives as that of the two goats in Leviticus xvi. The *Shepherd of Hermas* contains various examples. Clement of Rome gives the figurative application of the scroll-like line suspended from Rahab's window, which is adopted by so many of the fathers. In this connection great interest belongs to Justin Martyr, who exhibits acquaintance with several of the distinct senses which were subsequently formulated. Embracing Christianity as the only certain philosophy, and carrying much of his old Platonism with him into his new faith, he dealt with the Scriptures very much as he dealt with the classics. The history of the Old Testament (he seldom expounds the New) were a drapery covering broad spiritual truths. As the rising of Babel and the tower of Babel, so Jacob's marriage with Leah and Rachel denoted

Jehovah's revelation in the Jewish Church and the Christian. Every particular in prophetic passages like Gen. xlii. 9-12 had a mystical reference to Christ and His salvation, His passion being signified by the washing of the garments in wine, the Jews by the ass, the Gentiles by the colt.

The allegorical method, which offers itself as a natural expedient for harmonizing difficulties between religious faith and philosophical feeling, and which had been freely applied to Homer by Plato, found a most congenial home in Alexandria, where Philo's influence was strong. It became a recognized principle with the entire catechetical school, firmly rooted in the distinction which there prevailed between *mythos* and *logos*. Clement of Alexandria, who seems to have been the first to bring the New Testament on a level with the Old under its scope, finds a parabolic meaning in all Scripture, and affirms that the literal sense carries us simply to the elementary stage of Christian knowledge called faith, while it is only through the allegorical or mystical interpretation that we can reach that higher wisdom which implies insight into the essence, reason, and real relations of faith's objects. He speaks of a "tradition of the church," an "ecclesiastical canon," or "canon of the faith," which gives the key to the true understanding of Scripture, and is identified with the *symbolon* or spiritual apprehension of divine mysteries as that was first communicated by Christ to the apostles in oral form, and by them transmitted to their successors. This canon is described as "the consent and harmony of the law and the prophets with the covenant delivered during the Lord's presence." In accord with this Clement discovers in the Mosaic law three senses in addition to the natural. The terms in which the precepts are expressed are images of other things, rules for the direction of life, and predictions of the future. The high priest's robe is an emblem of the world of sense, the bells upon it as a symbol of the acceptable yoke of the Lord. The decalogue itself is spiritualized, the fifth commandment being taken to refer to the Heavenly Father, and that divine Wisdom which is the mother of the just.¹

A position of commanding importance must be claimed for Origen, whose genius secured wide and long continued acceptance for his greatest extravagances. Exact grammatical exegesis is by no means alien to his homilies and commentaries, and many of his strangest uses of Scripture may be viewed as practical applications rather than scholarly expositions. Fancifulness, however, is so predominant that he has been generally regarded as the chief allegorist of the Christian Church. Yet the disservice thus done by his example cannot cloud the lustre of his merits in Biblical studies. His Platonism, his adhesion to the Alexandrian idea of *γνῶσις*, his wish to defend and elucidate the Christian religion by reason and philosophy, his exaggerated notion of inspiration, combined to commend a mystical style of interpretation. In terms of the Platonic division of man into body, soul, and spirit, he held that Scripture had a threefold sense, *σωματικός, ψυχικός, πνευματικός*. The first, or obvious, sense was meant for the edification of the simple faith. The second, which was to be sought for under the letter, and embodied the soul of Scripture, exhibited the bearing of the word upon the practical needs of the moral life, and addressed itself to the more advanced. The third, which lay still deeper, and imparted the spirit of Scripture, disclosed pure unmixed truth, exercised the speculative powers, and was intended only for the perfect, such as are described in 1 Cor. ii. 6, 7. He has been sometimes credited with the promulgation of the fourfold distinction afterwards so current, especially in the Latin Church, and expressed in the couplet (given, e.g., by Lath.)—

¹ See especially Adom., vi. p. 676-80; also Benj., *Die Christliche Gnosis*, and Kavi., *Some Account of the Writings and Opinions of Clement of Alexandria*.

*Latere quæda docet, quæ aliis allegatur,
Moralis quæ agitur, quo tendit in ægea.*

Such terms, however, as topological, mystical, allegorical, pneumatur, analogical, are rather interchangeable with him. The literal sense, too, is so far from being dispensed with that he has even been regarded (e.g., by Ernest) as the first who secured for it its primary value, particularly in New Testament exegesis. But, while he maintains that the spirit and the letter are generally to be taken together, and admits that no small portion of the contents of Scripture (e.g., the decalogue, precepts of universal obligation, even many of the narratives) may not be allegorized, his practice is greatly in the direction of esteeming the literal sense only as the protecting shell of secret treasure. Wherever the letter yields, a meaning, which seems to him unworthy, or opposed to reason and possibility, a mystical sense is discovered. He stumbles at the record of creation when it introduces the sun after the third day, at many of the Mosaic ordinances, at the realism of Christ's temptation. He finds mysteries or figures of spiritual things in Eden, Abraham's wives, Rebecca's visit to the well, the water pots at Cana, and many other narratives. The later type of Alexandrian hermeneutics is seen in Cyril, who, without wholly abandoning the literal sense, carries typical interpretation into unqualified allegorical extremes in dogmatic and polemic interests.

The Western Church exhibited the same tendency, not only in the marked artificialities of such teachers as Hippolytus, Hilary, and Ambrose, but in the eminent instance of Augustine. Though not the first to attempt a statement of hermeneutical canons (having before him, for instance, the seven rules of Trichonius, which he states and enlarges at length), he constructed more of a system in this line of inquiry as in some others. Many of the principles which he enunciated in different parts of his writings, and most distinctly in his *De Doctrina Christiana*, are of permanent value. He conceives the object of interpretation to be the discovery of the thoughts of the writer exactly as he meant to express them. He shows that the real sense is often not to be got by insisting merely on expressions as they stand by themselves, that they must be compared with the immediate context, with similar passages elsewhere, and with the essentials of Christian doctrine, that faith and the aids of the Holy Spirit cannot supersede the use of science, that a reverent and sympathetic mind is indispensable. But, along with such rules as these, he propounds others which served as grounds for his allegorical procedure. He affirms, e.g., that whatever cannot clearly be seen to bear upon honesty of morals or the truth of faith must be taken figuratively. He speaks of several different modes of interpretation,—the historical, the etiological, the analogical, the allegorical. He usually practices the first and the last of these. His profound spiritual experience gave him a true insight than his canons indicated into many parts of Scripture, and above all into the Pauline epistles. Yet over most even of the New Testament he allows the allegorical fancy to range freely. His influence perpetuated the reign of the allegorical method for many centuries throughout the Western Church. In Gregory the Great, the Venerable Bede, Rabanus Maurus, Hugo de S. Caro, and many others, we see it steadily extending rather than merely maintaining its sway, until in Bonaventura we find the current four senses—historical, tropological, allegorical, analogical—enlarged to seven by the addition of the symbolical, synecdochical, and hyperbolic.

The second great hermeneutical tendency, which we call the *Dependent*, has an equally instructive history. It is easy to understand how extreme allegorizing would lead to a counter movement, and how this would be helped by the exigencies of dealing with heretics who were themselves

advocates of *γνῶσις*. The appeal soon came to be made to a rule of faith which may at first have meant nothing more than the harmony of Scripture teaching, but which was speedily identified with something outside Scripture, with the contents of doctrinal summaries, or with the verdict of exegetical tradition. The East and the West gave way alike to this bias, but the West first and most positively. In both we find early mention of an ecclesiastical canon or norm of truth. In the Church of the East, indeed, that took originally the form of an authoritative *γνῶσις* or private exposition of the esoteric meaning of Scripture handed down by careful tradition from Christ and the apostles, while in the Church of the West it was rather the voice of the church itself, and that soon the voice as formulated. Both churches, however, more or less distinctly recognized an ecclesiastical tradition represented in compends of doctrine which were used for catechetical and other purposes, and an interpretative tradition embodied in the expositions of influential doctors. Thus hermeneutical independence was sacrificed. In Irenaeus and Tertullian we see how a very natural reaction took this direction. The necessity of meeting *erists* who were greater adepts in arbitrary spiritualizing than any whom the church could present led them to protest against the practices. They saw the propriety of looking to Scripture itself for hermeneutical guidance, and of reasoning it from the deism of a mystical philosophy which threatened the life of its cardinal doctrines. They adopted a simpler reading of its message, and so far they deserve the name of pioneers in real historical interpretation. But, as appears in their gross christological expositions, their literalism was carried to excess. It came into conflict with the deeper declarations of Scripture, and this conflict they were tempted to compose by a relapse into fanciful methods. It created difficulties in their controversy with Gnostic opponents, and these they thought to remove by a final appeal to an authoritative tradition fixing the sense in which the sacred books which both parties used as witnesses to their doctrine were to be understood. This was to be found in its integrity in those ancient churches which had enjoyed direct apostolic teaching, and, as Irenaeus conceived, in some special way in that of Rome. Gradually the idea of a normative analogy of faith discovered within Scripture was externalized, and the standard of interpretation was looked for in ecclesiastical symbols and the formal decisions of the heads of the church. In this process, which issued in the Tridentine definition of the ultimate determination of the interpretation of Scripture as resident in the church, and the more recent declaration of the infallibility of the pope as the voice of the church, Vincent of Lerins claims particular notice. In his *Commonitorium*, for which we are indebted to the Semi-Pelagian controversy, he lays down rules for the attainment of certitude in belief. Faith is to be settled by two things, the authority of Scripture and the tradition of the church. The former is a perfect and adequate foundation. Yet the caprices of interpretation require it to be supplemented by the latter. The sense of Scripture is the sense in which the church understands it, and this tradition of the Catholic Church, which is to be accepted as the canon of hermeneutics, is defined as "quod ubique, quod semper, quod ab omnibus creditum est." This treatise, still retained in singular honour by large sections of the Christian Church, exhibits the hermeneutics which had been winning acceptance since the times of Irenaeus and Cyprian, and by which the Latin communion was led to bind itself. The result of the defence paid to the fathers in both churches, and especially in the West, was the renunciation of independent exegesis and the production of compilations of patristic comments. These *opul* or *Catenae* epitomized the interpretations of most of the great expositors, particularly Origen, Chrysostom,

Jerome, and Augustine, and were on the whole more successfully executed in the Greek Church than in the Latin. They were in use by the end of the 5th or beginning of the 6th century. Andreas of Caesarea, who belongs to the former period, or Olympiodorus, whose date is about the beginning of the 7th century, has sometimes been recognized as the earliest epitomizer, but the position is to be assigned rather to Procopius of Gaza, who comes between these two. For many centuries the most current divines took part in the preparation of *Catenae*, such as Cassiodorus (also a literalist), Bede (already cited as an allegorist), Alcuin, Hrabanus Maurus (often honored as the most learned interpreter of the 8th and 9th centuries), Haymo, Remigius, Sedulius, Theophylact, CDarius, Cassiodorus, Radbertus, and Aquinas. The *Catenae* of Aquinas on the gospels was of great value. Redactions of the *Catenae* were also made in course of time. These were the *Glossae*, which were known as *marginales* or *extrinsecas* when the comments were given on the margin, and *intertextuales* or *intertextuales* when these were introduced in the text. The most influential glossa of the second class was that of Anselm of Laon, who belongs to the end of the 11th and the beginning of the 12th century. Of the former the most important was the *Glossa ordinaria* of Walahfrid Strabo, which was esteemed the chief exegetical manual for some six centuries. Throughout the Middle Ages, till as these views of theological activity, dogmatic and polemical, harmonized, became more and more a tradition. The less the Bible was studied in a free spirit, the more it became the subject of stained penitence. Aquinas, indeed, though his practice was often in conflict with his theory, could still speak of the literal sense as that on which all the senses of Scripture are founded, and of argument as to be drawn only from that one literal sense and not from those senses which are expressed according to allegory (*Somma*, I, 1, art. 10). But at last independence was so completely resigned that John Gerson, the illustrious chancellor of Paris, was only the exponent of the prevalent opinion, when he declared that those who did not take the literal sense as the church defined it ought to be dealt with not by curious reasonings but by statutory penalties.

3. But alongside these two hermeneutical tendencies there can be traced from the earliest times, however obscurely or fitfully, a third which we term the *Historical*. Men like Irenaeus, Origen, Augustine, &c., were not wholly men cited for the exercise of a better method by their allegorical or dogmatic bias. There has been a line of interpreters, slender enough as that line has been at times, who have recognized it to be the exegetical object to discover the one sense intended by the writer himself, who have allowed allegory therefore only where the writers themselves indicated their mystical design, and who have laid the first importance on the grammatical sense and on the capacity of transporting oneself into the writer's position. Even Alexandria presents in the great Athanasius, and in Isidore notable instances of interpretation, who, though given to occasional spiritualizing, traced on the principle of the *abstraction* of Scripture (this especially in the case of Athanasius), and on the necessity of considering the occasion of each writing. But in direct antithesis to the allegorizing school of Alexandria stood the school of Antioch, which was grammatical and historical, with a tendency to an extreme literalism which yielded in not a few cases a jejune and uninspired exegesis. Theophilus and Julius Africanus may claim a place in this order. But the acknowledged representative of the Antiochene school are Lucian of Samosata, who is sometimes reckoned its real founder, Diodorus of Tarsus, Theodore of Mopsuestin, and above all John Chrysostom and Theodoret of the Syrian Cyprian. The last two, while not less careful of the

objective sense, surpassed the others in spiritual insight. Chrysostom abundantly in sound hermeneutical statements which strike a happy mean between Alexandrian rationalism and the unethical superficiality into which extreme Antiochene interpretation sank. He withstands the imposition of foreign senses as a practice dishonouring to the Word of God, and yet shows how much there is that must be taken otherwise than as it stands. He insists upon the importance of ascertaining the "scope" of a writing in order to a correct judgment of its separate declarations, on the necessity of the revelation of the Spirit, on the respect due to the harmony of Scripture with itself. He lays it down as a general principle that, when allegory is employed, the Bible also gives its interpretation as a check upon the untutored device of those who wish to allegorize (*Hom. in Genes v*). Theodoret exhibits a kindred sobriety, and, though occasionally guilty of seeking a secondary sense when the obvious sense seems too bald, ranks deservedly among the very best of ancient exegeses. Principles similar to the Antiochene prevailed for a long period also in the schools of Edessa and Nisibis. The objective language found representatives, too, in men like Basil of Cesarea, Gregory of Nazianzus, Gregory of Nyssa (although he was less decidedly literalist), and strongly advocated a non-verbal reading of Canticles in particular, Eriugena, and the laborious allegorist The last named champion of the Latin Church, although he too often drifted into fanciful and even purely interpretations, was strongly opposed both to the allegorists and the extreme literalists. Against the former he affirmed that the grammatical and historical sense must be held the fundamental thing. Against the latter he insisted that the figurative interpretation is not necessarily equivalent to the allegorical, and that the gospel is to be sought not in the words but in the sense of Scripture, not in the surface but in the marrow, not in the leaves of discourses but in the root of the idea (*Comm. in Galat. ii 14, in Epist. ad Galat. i 11*). In the unpopularity centuries which followed, this pure hermeneutical tendency appears occasionally in such instances as those of Druthmair, "the grammarian," CE monius, bishop of the Theobaldin Trices, who belongs to the 10th century, Theophylact, bishop of Achrida in Bulgaria, "the last of the fathers", Rupert of Deutz and Bartholomew Ziglabonus, who carry us into the 12th century.

A great impetus was given to independent hermeneutics by the Humanists and the precursors of the Reformation. An eminent position is occupied by Nicolaus de Lyra, to whose *Postille*, or brief commentaries on the whole Bible, Luther and the Reformers owed a debt expressed in the familiar dictum, "Si Lyra non lyreset, Lutherus non saltasset." The current fourfold division of the sense of Scripture still appeared in his writings; but for the most part only as a didactic device. He allowed occasional spiritualizing, but that mostly in the form of professed practical application of the proper sense. He declared anew the necessity of adhering to the plain objective meaning, likening the mystical interpretation which departs from the solid basis of the literal sense to a building which deviates from its foundation and inclines to its fall. On the side of grammar and philology the reaction was helped by Liviusius Valla and other Humanists, although the services of Ruettich in particular, great as they were in the assertion of exegetical freedom and in the restoration of linguistic science, were impaired by ebbaticistic predilections (*cf. especially his De verbo mystico*). On the religious side, something was achieved by men like Wycliffe, Huss, Wessel, who all perceived the primary importance of the grammatical method, and Faber Stapulenus (Lefèvre d'Étaples), who affirmed the sufficiency of the Word, and practised an independent, non-dogmatic exegesis. It is

matter of course that Erasmus should claim special notice in this connection. In this consummate scholar and versatile genius, who continued and vastly excelled all that had been attempted by Valla and others, and whose guidance the Reformers were wise enough to follow, notwithstanding the frequent deficiencies of his exegesis in depth and spiritual insight, we come at length upon a master hand that marks a great epoch. Indension clings indeed to his utterances on some subjects. He speaks with caution on the infallibility of the church and the church's head, although he lets us see that he rejects it. He admits the existence of occasional inaccuracies in the Scriptures. But he declares that these are so far from being disadvantageous to the gospel that they are tuned by the Spirit into a help to faith. He adds at the same time that if the authority of the entire Scripture should be supposed to be impaired by the presence of the smallest error in it, it is more than probable that none of the copies now used by the Catholic Church is so perfect as to be free from the intension of all mistakes, accidental or intentional (*cf. Annot. in Matt. ii 6*). But his clear enunciation of the interpreter's independence and the inquirer's obligation to become bound by the authority of no one (*1st. Lu. ii 36*), his advocacy of the translation and free circulation of the Scriptures, his repudiation of any other sense than what was meant to be conveyed, his sagacity in dealing with the figurative sections of both Testaments, his recognition of the need of a "pin curiositas" and a "curiositas pin" in the exposition of the divine word (*cf. Pref. to Epistol. in Ezechiel*), his practice of the true exegetical art in his *Paraphrases* and *Annotations*, contributed powerfully to the diffusion of better hermeneutical ideas.

The mightiest impetus was given by the Reformers. They were the heirs of what was best in the ancient school of Antioch and in the Humanistic revival. But they added to the philology, the grammar, the history, and the independent sense which were illustrated in these the spiritual insight and the personal religious interest which were so often wanting. The process by which they won their own way to a freer faith lifted them above tradition, mysticism, and unspiritual literalism. They profound religious experiences, intensified by the forces at work in an unexampled mental upheaval, made the Bible a new thing to them. It came to them as God's message, and they received it as the only rule of faith and life. It spoke immediately to their souls, and they saw it was to be interpreted by itself. They found it a message conveyed in historical form, and recognized the need of the appliances of language and history in order to read it. They perceived it to be a spiritual message, and discovered that the full recognition of it could come only by spiritual enlightenment. Believing it to be a message meant for all, they held it perpetual to the general intelligence of the piousful in all that concerns faith and morals, and affirmed, with Melancthon, "nam et certum est simplicem sententiam ubique quædam esse juxta præcepta grammaticæ, dialecticæ, et rhetoricæ." Each of the great Reformers did something to advance this true hermeneutical movement. Luther, Zwingle, and Calvin were alike imbued with the historic sense, Luther excelling in spiritual genius and a bold originality which carried him at times to extremes in the independence of his treatment of Scripture, Zwingle in an incisive perception which inclined strongly at times to subjective over-estimations, Calvin in a union of qualities which distinguished him as the foremost exegete of the Reformation. Profoundly reverencing Scripture as God's word, submitting to it as authoritative, yet not binding himself to any theory of its inspiration which would preclude the possibility of circumstantial inaccuracies (*cf. on Matt. xxv 9, Acts vi 10*), the Reformer of Geneva excelled all in freedom from arbitrary exposition, in reading

the Biblical statements in the light of historical occasion and intention, in laying the foundations of a truer typology, and in exhibiting with its Christward testimony the historical basis of Messianic prophecy. The collapse of Protestant exegesis were aided by Beza, Bucer, Bullinger, Oecolampadius, and others. At length the hermeneutics of the Reformation found symbolical expression in the Protestant definitions of the exclusive sufficiency of Scripture, its perspicuity under the use of the ordinary means and with the teaching of the Holy Spirit, its possession of a sense which is one and not manifold, and its interpretation by itself. In the *Clavis Scripturæ Sacræ* of M. Flacius Illyricus it was cast for the first time into systematic form, and dealt with theoretically.

With the Reformation objective exegesis may be said to have been firmly established. The conditions were also laid for further hermeneutical progress. Since then the principles of true grammatical historical interpretation have been gradually coming to be better understood and more successfully applied. This has not been the case, however, without frequent lapses. In various schools there have been revivals of old errors. There has been a return to the subjective tendency, e.g., in the "moral interpretation" of Kant, as well as in various forms of rationalistic and Spinozan exegesis. In accordance with his ideas of the empiric and local order of an historical faith, and his definition of morality as the essence of religion, Kant held that the judgments of the pure reason must be the test of religious faith, and that the literal sense, when it seems to convey a meaning adverse to morality, inconsistent with reason, or unworthy of God, must have a new meaning found for it. His hermeneutics, therefore, did not profess to rest with the sense intended by the writer, but reckoned it legitimate to adopt any possible sense which should be conformable to the interests of perfect morality. To the same tendency belong the "psychological interpretation" of Paulus and Eichhorn, and the mythical interpretation of Weiss and Strauss. Of these the former proposed to hermeneutics the task of distinguishing the qualities from the unexact impressions formed of facts by the sacred writers, while the latter sought principles by which the idea might be disentangled from the narrative vesture which it had worn for itself. Pietism, too, although its leaders, Spener and Francke, were of a better spirit, degenerated through its stanning after "edifying" interpretation into mystic and chiliasmic licence. The dependent tendency, again, formulated in the symbolical definitions on the subject of the Vulgate as the basis of exegesis, the church as the authoritative interpreter, and the pope as the infallible exponent of the church in official declarations on faith and morals, has become so firmly seated in the Roman Catholic communion that the interpreter's attitude to the church is capable of being compared by a Catholic author to that of a diplomatist acting in the spirit and interest of his prince.¹ It is followed, too, by that section of the English Church which defers to primitive tradition or the consent of the fathers of the first four centuries. Even among those who adhere to the Protestant positions there has been partial reaction in both directions. The subjective tendency has reasserted itself, e.g., in the artificial typology of the Occian school, although Cocceius himself rather deserves the credit of making Protestant theology, after it had entered its scholastic period, again more Biblical, and of enforcing the importance of a literal, contextual interpretation. The dependent tendency has reappeared where the "analogy of faith," instead of being kept to the original idea of the general contents of Scripture as gathered from the literal passages and used for a help to the understanding of the

obscure, has been identified with the creeds and employed as an external standard of interpretation.

But with partial retrogression there has been an advance on the whole in Protestant hermeneutics. To this interpreters of very different schools have contributed. Among these are to be mentioned Sal. Glassius, the author of the *Philologia Sacra*, Hugo Grotius, Abr. Calov, G. Calistus, J. J. Rambach, whose *Institutiones Hermeneuticæ Sacræ* exercised a salutary influence, notwithstanding his inclination to the priestly principle of "emphasis" in interpretation, J. A. Bengel, in whose *Gnomon* a happy union was effected between pietism and science, and J. B. Semler, who did much for the expansion of historical interpretation, notwithstanding the unpropitious results of his theory of accommodation. Of still greater importance was J. A. Eusebius, to whose celebrated *Institutio Interpretis Novi Testamenti* last century was indebted for the scientific presentation of the soundest hermeneutical principles on the philological side, Friedr. Schleiermacher, whose *Hermeneutik* abounds in fertile suggestions, and brings out for the first time the necessity of recognizing a specially Christian element in the language of the New Testament, and F. Lucke, who illustrates the just combination of the strictest scientific method with the primary qualification of spiritual sympathy with the Word in the true interpreter. Extensive use of hermeneutical method has been advocated, in the form of defining a special "psychological" (Staudlin), "theological" (Klausen, Landeas), or "dogmatic" (Döder) interpretation, or in the form of proposing new modes of interpretation, such as the "æsthetical" of Fries, the "pneumatical" of Beck, the "panharmonic" of Geinai. But whatever is valid in these schemes comes within the ordinary grammatical historical method. Properly understood, the historical side of that method covers all that concerns the transcription of the exegesis, not only into the times and circumstances of the composition of the books, but also into the position and personality of the authors. It embraces therefore that subjective quality which, however variously designated as the religious preparation, sympathy with the writers and their message, spiritual tact, or the illumination of the Holy Spirit, has been recognized by the best interpreters to be a primary and essential requisite. The development of these principles has been greatly helped by the grammatical studies of men like Gosenius, Fwald, Olshausen, and Böttcher in Hebrew, and Winer and Buttmann in Greek, by the literary, historical, critical, and theological investigations of Heider, Bear, Roth, Hofmann, and many others, and above all by the vigorous practice of scientific expositors such as De Wette, Bleek, Hupfeld, Lucke, Meyer, Grotius, Eilertsen, Lightfoot, and Duhren. Results as thus being gathered which will result in new enlargements of hermeneutical method. A clear insight is being gained into the genius of the language, which has already rescued New Testament Greek from positivist and Hebraist extremes, and into the nature of typology, the laws of prophecy, the relation of the two Testaments to each other, the historical delivery and development of their contents, the unity (so distinguishable from uniformity) which animates those different sections. In these directions there is the promise of further progress in hermeneutics. More exact inquiry into the presuppositions which underlie the Biblical doctrines will also tell upon the laws of interpretation. Differences in hermeneutical method, however, run up finally into differences of conception on the origin of the sacred literature, its intention, and the spirit which animates it. Unavoidably of view on the subject of what Scripture is and what its inspiration means, as seen in the symbols of the churches and in the widely divergent positions affirmed by representative theologians of different schools (cf., e.g., those expounded respectively by Chemnitz,

¹ Leclercq, *Gründzüge des biblischen Hermeneutik und Kritik*, p. 161, Gießen, 1899.

so frequently attached to him. The god with which he lulls men to sleep is the same sceptre that the ruler of the dead, Yama or Rhadamanthus, Minos or Hades, always bears (Kuhn in *Zft.*, iv p 123), he is also the sender of dreams, we find him worshipped among the Chthonian deities at Chidrus, and on vases accompanied by the Chthonian dog. We are now able to understand a fact which is perhaps the most interesting point connected with Hermes. Kuhn first pointed out the identity of the Greek *Hērmaios* with the Sanskrit *Saramēyas*, and though the connection has been doubted by various writers, as Mannhardt (*Wald- und Feld-Kulte*, i p 167) and others, yet no valid objection has ever been raised on etymological grounds (see Benfey in *Abhandl. Gott. Ges.*, 1877). Amid the difficulties which still envelop the translation and the mythology of the Vedas, it is, however, even more difficult to discover the original character of the two *Saramoyas* and their mother *Saramā*, than it is to determine the nature of Hermes. The two *Saramēyas* are mentioned twice in the *Rig Veda* (vi 55, x 14), they are two dogs, are said both to guard the way to the abode of the dead and refuse a passage to the impious, and also to act as the messengers of Yama, carrying away the souls when the time of death has arrived. *Saramā* also seems to be regarded as the messenger of the dog of India, and Hermes appears regularly as the companion and helper of all the little heroes on their adventures. One epithet of these dogs is *Yavaya*, spotted, which in its Greek form *Cerberus* (Benfey, *Vedica*, p 149) is the name of the dog that guards the gate of the lower world. Now we find in Rome that two *Lares praestites*, children of Mercury and Egria, are said to guard dwellings and streets in the form of dogs, and in the German legend the dog who attends the wild huntsman Wuotan, i. e., the sun hidden during the seven winter months, is closely related to the dwarfs or spirits of the dead, and is called by their name (Kuhn, *West. Sagen*, i p 99). So Hermes, whom we have seen as king of the dead, it is *psycho-paides*, also the conductor of souls to their future home, we may therefore count the dog (or dogs) as ultimately identical in character with the king of the dead. Some (on Chian in Kuhn's *Zft.*, x) has pointed out how these primitive conceptions commonly pass through the stage of animals before reaching that of gods, and in mythology we have the two stages preserved side by side as distinct beings. The *Indru Kubera*, lord of the treasures of the lower world, who may be identified with Pluto or with Hermes, is styled "Lord of the hosts of the Saramas."

In this account there has been no room left for the idea of Hermes as connected with the wind. The sun, after he has set at night, is the same as the sun hidden during the seven months of winter, who then rides abroad in the tempest. The wind is then easily conceived as his servant and messenger, and is often considered to carry away the souls of the dead (see *HERMES*). From his connexion with the wind, Hermes is represented with winged shoes. But with Roscher (*Leser des Wind Gott*) to see in Hermes simply the wind is to take a narrow view and to ignore the character of primitive Aryan thought.

In art, besides the Hermes already described, Hermes is in the archaic time represented as a man with pointed beard, wearing a chlamys and the broad hat called petasos, his symbols are the staff (*ῥαβδος*) and the winged shoes (*talapia*). The ideal type of Hermes was probably modelled after the statue by Praxiteles in the Heron at Olympia. This statue, which was recently discovered by the German expedition, represented the god leaning with his left arm on a rock and supporting on it the infant Bacchus. The right arm, which is lost, probably held the caduceus. The form shows a perfect combination of agility and strength.

Theol.*, Götting in *Heves.*, xxv, Müller, *Erkenntnis des Heros*, Mannathous, *Athen.*, Haupt in *Zft. f. Alterth.*, 1842, Ockermann, *Herms Olympien*, H D Müller in *Philologus*, xiv, Kuhn in Haupt's *Zft. f. d. Alterth.*, vi, Von Hahn, *Segensreich. Studien*, Roscher, *Hermes*. As usual, the fullest list of ancient authorities is to be found in Jacob, *Handbuch der Mythologie*. (W M K.)

HERMES, Gæza (1775-1831), a distinguished Catholic theologian, born on 22d April 1775, at Dreyerswald, in Westphalia, was educated at the gymnasium and university of Münster. His life presents no facts of importance after completing his course of study at Münster, he acted for some time as lecturer at the gymnasium and then as professor at the university. In 1820 he was called, as professor of theology, to the university of Bonn, where he remained till his death on 26th May 1831. Hermes was peculiarly adapted for the life and work of the professoriate. He had great gifts as a lecturer and teacher, and gathered round him at Bonn a devoted band of adherents. His works were *Untersuchungen über die wahre Wahrheit des Christenthums*, Münster, 1805, and *Einführung in die Christlich-katholische Theologie*, of which the first part, a philosophical introduction, was published in 1819, the second part, on positive theology, in 1820. The *Einführung* was never completed. His *Christlich-katholische Theologie* was published, from his lectures, after his death by two of his scholars, Achtenfeld and Baum, 3 vols. 1831-4.

The *Einführung* is a remarkable work, both in itself and in its effect upon Catholic theology in Germany. Few works of modern times have excited a more keen and bitter controversy. Hermes himself was very largely under the influence of the Kantian and Fichtean ideas, and though in the philosophical portion of his *Einführung* he criticises both these thinkers severely, rejects their doctrine of the moral law as the sole guarantee for the existence of God, and condemns their restricted view of the possibility and nature of revelation, enough remained of purely speculative material to render his system obnoxious to the Catholic Church. A very few years after his death, the contests between his followers and their opponents grew so heated that reference to the dispute was made in the papal see. The judgment consequent upon a review of Hermes's writings, undertaken in Rome in 1833, was adverse, and on 25th September 1835 a papal bull condemned both parts of the *Einführung* and the first volume of the *Dogmatik*. Two months later the remaining volumes of the *Dogmatik* were likewise condemned. The controversy did not cease with this condemnation, but not till 1846 was there any systematic attempt on the part of Catholic theology to examine and refute the Hegelian doctrine. In that year was published anonymously by F A Werner the most complete survey of the principles of the works of Hermes as contrasted with the orthodox Catholic faith (*Der Heimesanismus*, 1845). In 1847 the condemnation of 1835 was confirmed by Pius IX. A sufficient account of Hermes and the dispute 1835 by him will be found in K Werner, *Geschichte des Katholischen Theologs*, 1866, pp 405-409.

HERMES TRISMEGISTUS. The Egyptian "Hermis, Thaut, or Tat" (see vol vii p 718), who was identified by the Greeks more or less completely with their own Hermes, as described in the hieroglyphics by various authors, among which occurs that of "the great great" or twice great, with an added hieroglyphic (a lotus) also signifying "great." To him as scribe of the gods, "Lord of the divine words," "Seal of truth," was attributed the authorship of all the strictly sacred books, generally called by Greek authors *Hermetic*. These, according to Clement Alexandrinus, our sole ancient authority (*Strom.*, vi. p 268 *et seq.*), were forty-

shaped summit, is 20 miles long, extending north-east and south-west. The formation is a hard dark-grey crystalline limestone belonging to the Neocomian period, and full of fossils. The strata consist in some cases of white chalk covering the limestone, and on the south there are several basaltic outcrops. The mountain in spring is covered with snow, but in autumn there is occasionally none left, even in the ravines. To the height of 500 feet it is clothed with oaks and brush, while luxuriant vineyards abound. Above the snow limit the mountain is bare and covered with fine limestone shingle. The summit is a plateau from which three rocky knolls rise up, that on the west being the lowest, that on the south-east the highest. On the south slope of the latter are remains of the small temple or *aeolium* described by St. Jerome. A semicircular dwarf wall of good masonry runs round this peak, and a trench excavated in the rock may perhaps indicate the site of an altar. On the plateau is a cave about 25 feet square, with the entrance on the east. A rock column supports the roof, and a building once stood above. The view from Hermon is very extensive, embracing all Lebanon and the plains east of Damascus, with Palestine as far as Carmel and Tabor. On a clear day Jaffa may also be seen. Other small temples are found on the sides of Hermon, of which twelve in all have been explored. They face the east, and are dated by architects about 800 A.D. The most remarkable are those of *Deir el 'Ahasyeh*, *Irbit el 'Aheh*, *Hom Neha*, and *Tell Thatha*. At the ruined town called *Rukhlah* on the northern slopes are the remains of a temple, the stones of which have been built into a church. A large medallion 5 feet in diameter, with a head supposed to represent the sun god, is built into the wall. Several Greek inscriptions occur among these ruins. Foxes, wolves, and the Syrian bear are commonly found on Hermon, with various kinds of game. In the 12th century Psalm lxxxix. 12 was supposed to indicate the proximity of Hermon to Tabor. The conical hill immediately south of Tabor was thus named Little Hermon, and is still so called by some of the inhabitants of the district.

HERMOSILLO, a town of Mexico, state of Sonora, is situated at the entrance to a valley of remarkable fertility near the river Sonora at its confluence with the *Huacacila*, 40 miles south-west of Ures. Some of the principal houses are built of stone, but most of the dwellings are of adobe. The town possesses two churches, a prison, and a mint. Its rise and early prosperity were due to the discovery of gold mines in Sonora, but it now depends wholly on the fertility of the surrounding country, of which the principal products are cotton, wheat, grapes, and a great variety of fruits. The town is the commercial centre of Sonora. It has cotton manufactures, flour mills, and brandy distilleries, and carries on a considerable foreign trade by means of the port of Guaymas, which is 100 miles distant. The population is about 14,000.

HERMSDORF, generally known as *Niederhermsdorf*, a town of Prussia, in the government district of Bieslau and circle of Waldenburg. There are coal and iron mines and lime quarries in the vicinity, and in the town there is a large iron-works. The population in 1875 was 5981.

HERMUPOLIS. See SYRA.

HERNIA (a Latin term commonly derived from *hernia*, a sprout, but this origin is doubtful) is the protrusion of any viscus from its normal cavity, for example, *hernia cecalis* is the name given to a protrusion of the caecum, *hernia pulmonalis* a protrusion of a portion of the lung. The word may here be restricted to its most usual meaning, a protrusion of part of the contents of the abdomen from their normal position in the abdominal cavity, — in common language a "rupture." A rupture may occur at any weak point in the abdominal wall. The common situations are the groin (inguinal hernia), the upper part of the thigh

(femoral hernia), and the umbilicus or navel (umbilical hernia). The contents of a rupture may be any of the abdominal viscera, the more movable the viscera the more tendency there is to protrusion, and therefore we generally find that the small intestine and the omentum are most frequently displaced. The tumour may contain intestine alone (enterocoele), omentum alone (epiplocele), or a combination of intestine and omentum (enteroepiplocele). The predisposing cause to rupture is any weakness of the abdominal wall due (1) to natural conformity, as in inguinal hernia, which descends along the inguinal canal, a canal in which the cord lies in the male and the round ligament in the female, or in femoral hernia, in which the hernia descends along the femoral canal along with and to the inner side of the femoral vessels, (2) to any cause which weakens the wall locally, as an abscess or wound, (3) to general laxity of the tissues, as in weakly people, or after repeated pregnancies. This third cause only predisposes to hernia in so far as it may weaken an already weak part under the first and second heads. The exciting cause of hernia is generally some strain or over-exertion in any powerful effort, as lifting a heavy weight, jumping off a high wall, straining, as in difficult micturition or in consequence of constipation, or excessive coughing, as in chronic bronchitis. The pressure of the distended ovary and the anterior abdominal wall in front acting on the abdominal viscera tends to cause their protrusion at the weakest point. Rupture is either congenital or acquired. A child may be born with a hernia in the inguinal or umbilical region, the result of an arrest of development in these parts, or the rupture may be acquired, first appearing perhaps in adult life, the result of one or other of the accidents referred to above. Ruptures are most frequent at the extremes of life. Men suffer more frequently than women, because they are more liable to those accidents, being frequently exposed to intermittent work, such as the lifting of heavy weights.

At first the rupture is small, and with more or less rapidity it gradually increases in size, it varies from the size of a small marble to that of a child's head or even larger. The swelling which appears is spoken of as consisting of three parts, — the coverings, sac, and content. (1) The "coverings" are composed of the different structures which form the abdominal wall at the part where the rupture occurs. In femoral hernia the coverings are formed of the structures at the upper part of the thigh. These structures are stretched and may be thinned, in some cases they are condensed and matted together, the result of pressure, in others there is an increase in their thickness, the result of repeated attacks of inflammation. (2) The "sac" is composed of the peritoneum or *viscus* having the abdominal cavity, in some very rare cases the sac is wanting. The neck of the sac is the term used to designate the narrowed portion where the peritoneum forming the sac becomes continuous with the general peritoneal cavity. Very frequently the neck of the sac is thickened, indurated, and adherent to surrounding parts, because here the tendency to local inflammatory action is most marked, the pressure being greatest at this point. (3) The "contents" have already been defined. There are three distinct conditions in which we may find the contents of a hernial tumour. It may be either reducible, irreducible, or strangulated. A "reducible" hernia is one in which the contents can be pushed back into the abdomen. In some cases this is done with ease, in others it is a matter of great difficulty. At any moment a reducible hernia may become "irreducible," that is to say, its contents cannot be pushed back into the abdominal cavity. This may suddenly occur in consequence of an attack of constipation, or slowly, the irreducibility being at first partial and gradually becoming more

and more complete. Generally this is due to an increase in the size of the omentum, accompanied by inflammatory induration. A "strangulated" hernia is one in which the circulation of the blood through the hernial contents is interfered with. The interference is at first slight, but very rapidly tends to become more pronounced. At first there is congestion, this congestion may go on to inflammation, if unrelieved, the inflammation will end in mortification. The rapidity with which the change from simple congestion to mortification takes place will depend on the tightness of the constricting cause, as a rule the more rapidly a hernia forms in other words, the less time the surrounding tissues have to accommodate themselves to the protruding swelling, the greater the rapidity of the changes in the conditions of the contents. The constricting agent may be one or other of the structures which form the boundaries of the openings through which the hernia has travelled in its gradual course through the abdominal wall, or it may lie in the neck of the sac, which has become thickened in consequence of inflammation.

Reducible Hernia—The symptoms of reducible hernia show themselves in a soft conical tumour, protruding when it contains intestine, doughy when it contains omentum, a combination of elasticity and doughiness when both are present, its size increasing in the erect, and diminishing in the horizontal posture, whereas as a rule it grows larger by the motion of the bowels, and becomes most troublesome in the daytime, more especially towards evening. There is a more or less distinct impulse on coughing, and when the intestinal contents are pushed back into the abdomen a gringing sensation is perceived by the finger, which is usually met with in any part of the abdominal wall, but the chief situations are—(a) the inguinal region, in which the neck of the tumour lies immediately above Poupart's ligament, (b) the ilio-lumbar region, in which the neck of the tumour lies immediately below the umbilical region, in which the tumour sits at the navel. At the inguinal hernia increases in size it tends to pass into the scrotum in the male, into the labium in the female, while the femoral hernia, appearing first in the inguinal, tends gradually as it increases in size to pass upwards superior to Poupart's ligament.

The treatment of reducible hernia consists in pushing back the contents of the tumour into the abdomen, and supplying a truss or elastic bandage in order to prevent the contents from again escaping. The younger the patient the more elastic tissues of the tumour are, the more easily, and the more it tends to contraction of the channel through which the hernia protrudes is greater. The truss is frequently put aside at night, because in the horizontal posture the tendency of the contents to descend is greatly lessened. The truss or bandage should, however, be worn day and night. If, after the hernia is once returned, it never again allowed to come down, there is a probability of a cure taking place, but if it is allowed to come down occasionally, as it may do even during the night, in consequence of cough or from turning in bed, the truss is essential, and the constricting process which may have been going on for weeks is undone.

It is unnecessary to describe the multitudinous varieties of trusses. When the truss is desired, the surgeon has so far to do its utility, the necessary amount of pressure being obtained by means of a wax spring, to which a pul is attached. The pul should be so arranged as to press, not into the opening through which the hernia has come, but into the sac, so as to force the contents into the abdomen, and so to force the contents into the abdomen. The main pressure should be in the neighbourhood of the neck of the sac, if the pul presses into the opening, the tendency is to keep the opening patent. The principle of the simple shaped parts have been recommended for umbilical hernia, is evil, a flat pul properly applied and held in position by an elastic bandage is the proper arrangement for restraining an umbilical hernia. No truss is to be applied until the hernia is completely reduced, it will only do harm by pressing on the contents of the unreduced hernia. In some hernia, generally those of large size, it is found impossible to keep them up by means of a truss, in such cases an elastic bandage will sometimes affect the object, in other numerous operations have been recommended. They are spoken of as "the radical cure of hernia," in contradistinction to the so called "palliative treatment by means of a truss." An attempt has been made to alter the size of the opening of a truss. The principle involved in the operations described are (1) obliteration of the neck of the sac, (2) obliteration of the channel through which the hernia has de-

sended, (3) obliteration of the sac itself, (4) plugging of the channel by invaginating the loose skin. The first and second are specially important, as in them the surgeon imitates nature's way of attempting to cure the tendency to hernial protrusion.

Reducible Hernia—Then the main symptoms of a tumour in one or other of the situations already referred to, of long standing and generally of large size, in which the contents of the tumour, as whole or in part, cannot be pushed back into the abdomen. The irreducibility is due either to the large size or to changes which have taken place in the contents, either in the tissues or adhesions. Such a tumour is a constant source of danger, its contents are liable, from their exposed situation, to injury from external violence, it is liable to strangulation, and tendency to inflammation, if it becomes strangulated, the contents may inflame, and strangulation may occur secondarily to the inflammation. It is accompanied by dragging sensations referred to the abdomen, colic, dyspepsia, and constipation, which may in its turn lead to obstruction, that is to say, a stoppage of the passage of the contents of the part portion of the intestinal canal which lies in the hernial tumour. When an irreducible hernia becomes painful and tender, a local tenderness has occurred, which resembles in many of its symptoms a case of strangulation.

The treatment of irreducible hernia may be palliative, a big truss may be worn to prevent the swelling from getting larger, the truss must be kept open, and all irregularities of diet avoided. A person with such a hernia is in constant danger, and more than palliation is required. An attempt should be made to reduce the hernia, (1) by laying the patient on his back, (2) by the use of butters, administering purgatives, and starving him (preventing attention to these points may so reduce the size of the contents that the hernia may be reduced), (3) by the use of the hand, (4) by the use of the hand, as to press continuously on the tumour, and gradually push it back into the abdominal cavity. By this simple means large irreducible hernia, which have withstood all attempts at reduction, have been returned, and the abdomen is relieved, and the patient may be kept continuously applied for a few days. (5) The surgeon may cut down on the hernia, and cut away the protruding protrusions, open the sac, divide any omental adhesions, ligature and cut away in dashed manner, return the contents of the tumour into the abdominal cavity. Such an operation is unquestionable unless other means have been fairly tried and failed, and unless the hernia is giving rise to such symptoms that the usefulness of the patient is interfered with.

Strangulated Hernia—In this the contents are constricted, and the flow of blood into the tumour and from the tumour is stopped. The symptoms are—nausea, vomiting, flatulence, distension, a time of focal mist, a twisting, burning pain generally referred to the umbilicus, intestinal obstruction, a quick watery pulse, pain on pressure over the tumour and in the abdomen near the tumour, the abdomen tense and tympanitic, and no impulse on coughing, because the contents of the tumour are practically cut off from the general abdominal contents. The patient has an anxious expression. Soon or later, from eight hours to eight days, if the strangulation is unrelieved, the tumour will become livid and emphysematous, mortification has occurred, and gangrene of the wall of the neck of the sac will take place, followed by extensive extension of the intestinal contents into the abdominal cavity, the patient becomes collapsed, and dies comatose.

The treatment of a strangulated hernia admits of no delay, delay is fatal. If the symptoms are not very acute, and if the case is seen early, attempts may be made by large laxatives, by the application of cold to the tumour to reduce the congested condition and relieve the strangulation. But these attempts must not be persevered with for more than two or three hours. If the strangulation continues, an attempt should be made to reduce the hernia, as one which admits of no delay. On no account should be administered, another attempt to return the contents by pressure (named "the taxis") should be made. If this has already been fairly tried, and if the symptoms are not relieved, no prolonged attempts at taxis are justifiable, because the condition of the hernial contents may be such that they cannot bear the pressure. The taxis to be successful should be made in a direction opposite to the direction of the protrusion. The inguinal hernia should be pressed upwards, outwards, and backwards, the femoral hernia downwards, backwards, and upwards. The larger the hernia the greater is the chance of success. The slightest gurgling indicates the escape of air. If the tumour does not subside when the surgeon must cut down on the tumour, carefully dividing the different coverings until he reaches the sac. The sac is then opened, the constrictor divided, care being taken not to injure the bowel, and the contents are returned, the sac is then examined, and if it is glistening, how ever black it may be, it is returned into the abdomen. If it has lost its glistening aspect, if it is like "wet parchment," then the case is very doubtful. It is doubtful, relieve the contents, and leave the bowel in the sac. Never open the bowel, however bad it looks, it may recover, and if it does not burst for some hours afterwards, the chances are that adhesions may form at the neck of the sac and lessen the risk

of extravasation into the abdominal cavity—a fecal fistula will be the result. The operation, if healthy, may be returned, or it can be ligated and indurated, it may be ligated and cut off. After the bowel is returned the wound is sewn up, and a pad and flannel bandage applied. A dose of opium should be given to prevent movement of the bowels. On the third day a dose of castor oil is administered if the bowels do not open naturally. A tube is applied after the wound is healed before the patient is allowed to get out of bed. Many complications which may occur cannot here be discussed. Any one suffering from hemorrhoids should take great care to obtain an intimately fitting towel, and should remember that, whenever any symptoms resembling in any degree those of strabismus occur, any delay in the treatment is not only dangerous but may prove fatal. A medical man should at once be communicated with. It is in this time he to remember that when a patient asks his advice, complaining of symptoms resembling strangulation, he must examine all the situations where hernia may occur, because the hernial tumour may be so small that it has escaped the notice of the patient. Any operation on the patient's part that he does not submit to by careful inspection and in mild examination. If an operation is necessary he may with confidence say that the operation is not in itself a dangerous one, while, on the other hand, he can assure the patient that any delay is most certainly extremely dangerous. (70)

HERMOSAND, chief town and seat of the administration of the land of Western Norland on the east coast of Sweden, is built on the island of Heron (connected with the mainland by bridges), about 3 miles south of the mouth of the Angerman river, and 230 miles north of Stockholm. It is the seat of a bishop and possesses a fine church, erected in 1843-46. There are engine works, timber-yards, saw mills, and various manufactures in the town. The harbour is good. In 1878, 35 vessels, chiefly engaged in the fish trade, with a total burden of 7,698 tons, entered and cleared at the port. Tax is also exported, and there is an institution for pisciculture in the town. Heron was founded in 1854, and received its first town privileges from John III. in 1857. The population in 1876 was 4912.

HERO AND LEANDER Hero, the beautiful priestess of Venus at Sestos, was there seen by Leander, a youth of Abydos, at the celebration of the festival of Venus and Adonis. He became deeply enamoured of her, and found that day an opportunity of declaring his passion, which she returned, and as her position rendered their marriage impossible, they agreed to carry on a clandestine intercourse. Nightly Hero placed a lamp in the top of the tower where she dwelt by the sea, and Leander, guided by it, swam the dangerous Hellespont. One stormy night the lamp was blown out, and Leander perished. On finding his body next morning on the shore, Hero flung herself into the waves.

Reference is made to this famous tale by *Virgil* (*Georg.*, in 358) and by *Statius* (*Thib.*, in 638). Ovid, who has twice composed an epistle from Leander to Hero, and one from Hero to Leander. But the story is best known from the work of *Marcius* (see *Miles*), which has been repeatedly translated into modern languages. The *Hero and Leander* of Marlowe and Chapman is an imitation and expansion of the work of Marcius.

HEROD was the name of a family of Idumean origin, which displaced the Asmonaeans as the rulers of Judaea. The founder of the dynasty, and its most notable representative in every way, was Herod the Great, who was king of the Jews for about thirty-seven years, from 40 to 4 B.C. Herod's father was Antipater, though an Idumean, which broke out in the family of Alexander Jannæus, attacked himself to Hyrcanus, the weak-minded son of Alexander. In this way Antipater, though an Idumean, soon became the most powerful man in Judaea, and in the Alexandrian war gave such effectual help to Julius Caesar that the dictator made him procurator of Judaea, Hyrcanus being high priest (47 B.C.). The same year, at the age of twenty-five, Herod was appointed governor of Galilee by his father. He soon gave proof of the remarkable energy of his character in rooting out the bandits

who infested his province, but his summary measures gave a handle to the enemies of his house at Jerusalem, and he was summoned before the sanhedrin. There he appeared, not in the garb of an accused person, but gorgeously attired, and attended by a guard of soldiers. He found it expedient, however, to withdraw from Jerusalem without awaiting the sentence. He retired to Syria, where he met with a gracious reception from Sextus Cæsar, who appointed him governor of Coele-Syria. Herod now marched with an army against Jerusalem, but at the persuasion of his father and brother he was induced to depart without exacting vengeance on his enemies. After the death of Cæsar, the fortunes of Herod were affected by all the changes which befell the Roman state. When Cassius took the command in the East, and began to gather his strength for the final struggle which was decided at Philippi, Herod managed to win his favour by the readiness with which he raised his share of the heavy exactions imposed upon the East. About the same time his father was poisoned, and to Herod fell the task of avenging his death, as well as of supporting the interests of his house in Palestine. After Philippi he gained Antony over by large presents of money. He and his brother Phasael were appointed tetrarchs of Judaea. In 40 B.C. the Parthians appeared upon the scene, overran the whole of Syria, and placed on the throne of Judaea Antigonus, son of Aristobolus, and representative of the royal branch of the Asmonæan house. Herod was completely overpowered, and, after placing his relatives in safety, so far as he could, he hastened to Rome to lay his case before Antony and Octavianus. He succeeded by his eloquence and flattery, for, while he meant only to advocate the claims of Hyrcanus the Asmonæan, the two leaders of the state made him king of Judaea. Herod returned home without delay, and set about the task of winning the kingdom allotted to him. Owing chiefly to the slackness of the Roman generals who should have helped him, it was three years before he succeeded in making himself master of it. Before that event he had married the beautiful Mariamne, a princess of the Asmonæan house, a granddaughter both of Aristobolus and Hyrcanus. Herod's early measures were cruel, he put to death all the members of the sanhedrin except two, and spared no one that was likely to stir in his way. Aristobolus, the youthful brother of Mariamne, whom he had appointed high priest, he caused to be treacherously drowned because he was too popular with the patriotic party. On this occasion Alexandria, mother of Aristobolus, induced Cleopatra to take her part, and Herod had to appear before Antony to answer the charge of murdering the prince. Again Herod knew how to gain the favour of the Roman emperor, and he returned home a Roman. During the war of Actium, Herod had the good fortune to be engaged in a war with the king of Arabia on Antony's behalf, and so escaped the risk of fighting against Octavianus. Yet he recognized the danger of his position, the friend of Antony, and faced it with his usual courage and foresight. Hastening to Rhodes (30 B.C.), he appeared in the presence of the conqueror, and avowing his loyalty to his friend Antony, professed the same faithful service to Octavianus. Octavianus was gracious, and remained the constant friend and patron of Herod to the end. This was the last crisis of Herod's life, he was hereafterward undisturbed king of Judaea, and next to Agrippa the most trusted friend of Augustus. But while the friend of the great, and prosperous in all external relations, Nemesis pursued him in his family. When summoned to answer for himself before Antony, and again on his journey to Rhodes, he left the beautiful and beloved Mariamne in charge of one of his friends, but with the cruel injunction that she should be put to death should anything serious befall himself. On both occasions Mariamne discovered the secret, and, instead

of regarding the command as a proof of his jealous love, abhorred it as another instance of the cruelty which had not spared so many of his nearest relatives. A horrible tragedy ensued. Mariamne openly expressed her disgust, and Herod, furious with rage, jealousy, and rejected love, ordered her death. The violence of his feelings threw him into a dangerous malady, and even drove him to the verge of insanity. His mind never recovered its healthy tone, and in later years the avenger again overtook him. In the meantime his government was marked by the greatest magnificence and apparent success. His turbulent subjects were kept tolerably quiet in spite of heavy taxes. He managed to gratify his love for Greek and Roman life, and yet he avoided wounding too deeply the susceptibilities of the Jews. The magnificent buildings which he raised were the most brilliant products of his reign. He rebuilt Samaria, calling it Sebaste, from the Greek name for Augustus. He converted the small town of Stabæ's Tower into a magnificent seaport with an artificial harbor, under the name of Caesarea. These and other towns which he built were furnished with temples, theatres, aqueducts, and all the other ornamental and useful appliances of Greek and Roman life. In the city of Jerusalem even he built a theatre, and an amphitheatre outside of it. A most patriotic work was the rebuilding of the temple (begin 20 a c.), which had sunk and gone into ruin during the late troubles, it was on a very magnificent scale, and lasted nine years and a half, even then being unfinished. Equally necessary and equally significant of his relation to his subjects was the construction of strong fortresses in various parts of the country. The last years of Herod's life were darkened by the return of those family troubles which had previously overtaken it. His two sons by Mariamne had been educated at Rome, and returned, 17 a c., to Judea. Their Asmonean descent, their youth, beauty, and accomplishments, and their too interesting history gained them the most enthusiastic popularity among the Jews. Their father himself was proud of them. But Theonaeus and Salome, brother and sister of Herod, did all they could to sow jealousy and suspicion. Herod's mind was too painfully open to dark insinuations, and he recalled his eldest son Antipater to counterbalance the influence of the Asmonean princes. After the arrival of Antipater, who was a most unscrupulous plottor, there was no more peace or security at the court of Herod, things went from bad to worse, till after many years of the darkest intrigue and the bitterest domestic contention, the two sons of Mariamne were strangled at Sebaste. Soon after the clearest proof was discovered of a conspiracy which Antipater had formed with Theonaeus against the life of Herod himself. The order for the death of Antipater was given by Herod from his death-bed. His health had long been failing, after the onerous toils of both mind and body, he died 4 p c. The birth of Christ took place in the same year as Herod's death, but this, as is well known, occurred four years before the date fixed as the beginning of the Christian era. The massacre of the little children at Bethlehem is not mentioned by Josephus among the horrors of Herod's last days. He was buried with great magnificence. His will, by which the greater part of his dominions was bequeathed to his sons by Maltheus, a Samaritan, was confirmed by Augustus.

Herod's name is doubtless one of the most repulsive in history. He was a man of wonderful energy and sagacity. He saw clearly that Rome was the hinge on which everything turned, and that no policy could be successful which did not depend upon her leading strings. His skill in understanding these men, in conciliating them, and making himself useful to them, was very great. Thus he made the successive masters of the world his willing friends, and out of all the crises of his fate emerged victo-

rious. But his hands were red with the blood of his own household, when his position or his interests were touched no scruple could arrest him. All that can be said in his favour is that many of his cruel measures cost him unspeakable agony of mind, and that he was simply more exact than his rivals at the weapons which were in common use in the political life of the time.

The great source for the life of Herod is Josephus, but such writers as Strabo in *Deon Cassius* are of service in further illustrating it. Useful modern works are: Hume's *Hist. des Siècles*, *Zeitgeschichte*, the work of the same name by Schœner, *David, Geschichte des Volkes Israel*, vol. 1, Kuhn, *Geschichte Israels von Nabat*, vol. 1, and Milman's *History of the Jews*, vol. 1 (T. K.).

HEROD ANTIPAS, son of Herod the Great by the Samaritan Maltheus, and full brother of Archelaus, received as his share of his father's dominions the provinces of Galilee and Peraea. Like his father, Antipas had a turn for architecture. He rebuilt and fortified the town of Sepphoris, he also fortified Betharamphæ, and called it Julias after the wife of the emperor. Above all he founded the important town of Tiberias on the west shore of the Sea of Galilee, with institutions of a distinctly Greek character. Antipas is mentioned more than once in gospel history under the name of Herod. He it was who was called a "fox" by Christ. He is erroneously spoken of as a king in Mark vi 15.

It was to him that Jesus was sent by Pilate to be tried. But it is in connexion with his wife Herodias that he is best known, and it was through her that his misfortunes arose. He was married first of all to a daughter of Aretas, the Arabian king, but, making the acquaintance of Herodias, the wife of his brother Philip (not the tetrarch), during a visit to Rome, he was fascinated by her and arranged to marry her. Meantime his Arabian wife discovered the plan and escaped to his father, who made war on Herod, and completely defeated his army. John the Baptist condemned his marriage with Herodias, and in consequence was put to death in the way described in the gospels and in Josephus. When Herodias's brother Agrippa was appointed king of Caligula, she was determined to see her husband attain to an equal eminence, and persuaded him, though naturally of a quiet and unambitious temperament, to make the journey to Rome to crave a crown from the emperor Agrippa, however, managed to influence Caligula against him. Antipas was deprived of his dominions, and banished to Lyons, Herodias voluntarily sharing his exile.

HEROD PHILIP, son of Herod the Great by Cleopatra of Jerusalem, received the tetrachate of Ituraea and other districts to the N E of the Jordan. He is a different person from the first husband of Herodias, also called Philip by St Mark (vi 17), and was married to Salome the daughter of Herodias. Philip is described as an excellent ruler, who loved peace, and was careful to maintain justice, and spent his time in his own territories. He was also a builder of cities, one of which was Caesarea Philippi, and another was Bethsaida, which he called Julias. He died after a reign of thirty-seven years, and his dominions were incorporated in the province of Syria.

HERODIAN'S (*Ἡροδιανός*), a sect or party mentioned in Scripture as having on two occasions—once in Galilee, and again in Jerusalem—manifested an unfriendly disposition towards Jesus (Mark vii 6, xii 13, Matt xiii 6, cf also Mark viii 15). In each of these cases their name is coupled with that of the Pharisees. According to many interpreters the courtiers or soldiers of Herod Antipas ("Milites Herodis," Jerome, "Dives Herodes," Luther) are intended, but more probably the Herodians were a public political party, who distinguished themselves from the two great historical parties of post exilic Judaism by the fact that they were and had been sincerely friendly to Herod the Great and to his dynasty (cf such formations as "Caesarian," "Pompeian"). For the evidence which goes

to show that neither the Pharisees nor the Sadducees as such could in consistency have been really thus friendly, reference may be made to Haurath (especially his *New Testamentische Zeitgeschichte*), and article "Herodian" in Schenkel's *Bibel-Lexikon*, and to Wellhausen (*Pharisæer u. Sadduceer*, 1873). It is possible that, to gain adherents, the Herodian party may have been in the habit of representing that the establishment of a Herodian dynasty would be favourable to the realization of the theocracy, and this in turn may suggest some explanation of Titullian's (*De Præci*) palpably absurd allegation that the Herodians regarded Herod himself as the Messiah.

HERODIANUS, the author of a Greek history of the period extending from 180 to 288 A.D. Of his origin and condition in life very little is known. He was in Rome in 303, and seems to have held some public office. It has been conjectured that he was first "procurator Cæsaris" and afterwards "legatus" of the Sicilian provinces, and that, while fulfilling his official duties, he wrote at intervals the history which bears his name. It is entitled *Ἡρωδιανὸς τῆς περὶ Μάρκου Βασιλέως ἱστορίαν βιβλία δέκα*, and it narrates the events of the fifty-eight years that intervened between the death of Marcus Aurelius and the proclamation of Gordianus III. The narrative is of special value for the reigns of the emperors subsequent to Alexander Severus, with whom the work of Dion Cassius ends. As an historian Herodianus has prominent merits and defects. His work has the value that attaches to a record written by one chronicling the events of his own times, gifted with respectable powers of observation, indubitable candour, and independence of view. But he prefers the interest of style to the interest of truth, and is thus led into exaggerations and errors. The inner life and thought of Rome, the formidable barbarian pressure on her borders, are alike unheeded, that he may blazon his pages with the dazzling vicissitudes of the purple. Though the somewhat sobriety of declamations which he introduces are apt to become tedious, his story is on the whole clear, graceful, and vivacious. The frequent antitheses and studied tricks of phrase savour of the rhetorical schools. Imitations of Thucydides and Latinus are frequent. Yet in the main his style retains an original cast, a genuine unborrowed beauty, and contrasts favourably with the thin, affected Athenism of the period. Extensive use has been made of Herodianus by later chroniclers. His history was first translated into Latin in the end of the 15th century, by the famous Angelo Polissano.

HERODIANUS, *ÆLIUS*, a famous grammarian of antiquity, called by Præsius "maximus auctor auctis grammaticis." He was the son of the grammarian Apollonius, was born at Alexandria, and resided at Rome. He was patronized by the emperor Marcus Aurelius (161-180 A.D.), to whom he dedicated his great treatise on prosody. This was a work in twenty books, called *Καθολικὴ Προσῳδία*, which included also an account of the etymological part of grammar. An epitome of it has been preserved. Abstracts of a treatise on difficult words and peculiar forms, called *Ἑρμηνευτικόν*, are also extant. Besides these, Herodianus wrote various other treatises, but of the large number of titles quoted, some are probably merely names for parts of larger works. Only one of them has come down complete—a treatise on monosyllables (*περὶ μονοσύλλων λέξεων*). Numerous quotations, however, and considerable fragments still exist.

Fabricius (*Bibl. Græc.* vi. 278 sqq.) enumerates his works and the passages where they are quoted. Lenz (*Herodiani technæ reliquæ*, Lips. 1887-70) has collected and thoroughly edited all the remains.

HERODOTUS, according to the best authorities, was born in or about the year 484 B.C. He was a native of Halicarnassus, a city which belonged originally to the Dorian Hexapolis, situated towards the south-western corner

of Asia Minor, but which from a date considerably anterior to the birth of Herodotus had been excluded from the confederacy, and was an isolated Greek town, dependent upon the Persians. Herodotus was thus born a Persian subject, and such he continued until he was thirty or five-and-thirty years of age. At the time of his birth, Halicarnassus was under the rule of a queen called Artemisia, who had been allowed by the Persians to succeed to the sovereignty of her husband, and was mistress, not only of Halicarnassus, but also of Cos, Nisyrus, and Calydna. The year of her death is unknown, but she left her crown to her son Pisindarus (born about 498 B.C.), who was succeeded upon the throne by his son Lygdamis about the time that Herodotus grew to manhood. The family of Herodotus belonged to the upper rank of the citizens. His father was named Lyxes, and his mother Ithone, or Diyo. He had a brother Theodote, and an uncle or cousin called Panyasis, who was an epic poet, and a personage of so much importance that the tyrant Lygdamis, suspecting him of treasonable projects, put him to death. It is likely that Herodotus derived from this near relative that love of letters which led him at an early age to the careful study of the existing Greek literature, and determined him ultimately to engage in the composition of his great work. It is probable also that he shared his relative's political opinions, and was either exiled from Halicarnassus, or quitted it voluntarily, at the time of his execution.

Of the education of Herodotus no more can be said than that it was thoroughly Greek, and embraced no doubt the three subjects essential to a Greek liberal education—grammar, gymnastic training, and music. There is no reason to suppose that he went beyond the walls of his native city for instruction in this, the ordinary, curriculum, or that he enjoyed any special advantages in respect of these early studies. They would be regarded as completed when he attained the age of eighteen, and took rank among the "ephebi" or "enesis" of his native city. Under ordinary circumstances a Greek of this age began at once his duties as a citizen, and found in the excitement of political life sufficient employment for his growing energies. But when a city was ruled by a despot or tyrant, this could not be a fitting, no political life worthy of the name existed, and youths of spirit, more especially those of superior abilities, had to cast about for some other field in which to distinguish themselves. Herodotus may thus have had his thoughts turned to literature as furnishing a not unsatisfactory career, and may well have been encouraged in his choice by the example of Panyasis, who, whether his cousin or his uncle, was certainly his elder, and had already gained a reputation by his writings when Herodotus was still an infant. At any rate it is clear from the extant work of Herodotus that he must have devoted himself early to the literary life, and commenced that extensive course of reading which rendered him one of the most instructive as well as one of the most charming of ancient writers. The poetical literature of Greece was in his time already large, the prose literature was more extensive than is generally supposed, yet Herodotus shows an intimate acquaintance with the whole of it. He has drunk at the Homeric cistern till his entire being is impregnated with the influence thence derived. The *Iliad* and the *Odyssey* are as familiar to him as Shakespeare to the most highly educated of modern Englishmen. He is acquainted with the poems of the epic cycle, the *Cypria*, the *Epigoni*, &c. He quotes or otherwise shows familiarity with the writings of Hesiod, Alcman, Musæus, Bacus, Lycabettus, Archilochus of Paros, Alcman, Sappho, Semon, Egeon, Antistes of Phocæa, Simonides of Ceos, Phrynicus, Æschylus, and Pindar. He quotes and criticizes Hecateus, the best of the prose writers who had preceded him, and makes numerous allusions to other authors

of the same class. It may be questioned whether there was any single work of importance in the whole range of extant Greek literature with the contents of which Herodotus had not made himself acquainted by the time that he undertook the composition of his "History."

It must not, however, be supposed that the great Haliarnassian was at any time a mere idler student. There can be no reasonable doubt that from a very early age his inquiring disposition led him to engage in travels, both in Greece and in foreign countries, which must have been continued year after year for a considerable period, and which made him as familiar with men as with books. He traversed Asia Minor and European Greece in all directions, probably more than once, he visited all the most important islands of the Archipelago,—Rhodes, Cyprus, Delos, Paros, Thasos, Samothrace, Chios, Samos, Cythra, and Ægina. He undertook the long and perilous journey from Sardis to the Persian capital Susa, passed some considerable time at Babylon, and went a voyage to Colchis, and another along the western shores of the Black Sea as far as the estuary of the Danube; he travelled in Scythia and in Thrace, visited Zante and Magna Græcia, explored the antiquaries of Tyre, coasted along the shores of Palestine, saw Gaza, and made a long stay in Egypt. At the most moderate estimate, his travels covered a space of thirty-one degrees of longitude, or 1700 miles, twenty-four of latitude, or nearly the same distance. Nor was he content, like the modern tourist, with hasty glimpses of the countries which he visited. At all the more interesting sites he took up his abode for a time, he examined, he inquired, he made measurements, he accumulated materials. Having in his mind the scheme of his great work, he gave ample time to the elaboration of all its parts, and took care to obtain by personal observation a full knowledge of all the various countries which were to form the scene of his narrative.

His travels of Herodotus seem to have been chiefly accomplished between his twentieth and his thirty-seventh years (464–417 B.C.). It was probably in his early manhood that as a Persian subject he visited Susa and Babylon, taking advantage of the Persian system of posts which he describes in his fifth book. His residence in Egypt must, on the other hand, have been subsequent to 460 B.C., since he saw the skulls of the Persians slain by Inarus in that year. Skulls are rarely visible on a battlefield for more than two or three seasons after the fight, and we may therefore presume that it was during the reign of Inarus (460–454 B.C.), when the Athenians had great authority in Egypt, that he visited the country, making himself known as a learned Greek, and therefore receiving favour and attention on the part of the Egyptians, who were so much beholden to his countrymen. On his return from Egypt, as he proceeded along the Syrian shore, he seems to have landed at Tyre, and from thence to have gone to Thasos, which lay off the coast of Thrace. His Scythian travels are thought to have taken place prior to 450 B.C.

It is a question of some interest from what centre or centres these various expeditions were made. Up to the time of the execution of Panyasis, which is placed by chronologists in or about the year 457 B.C., there is every reason to believe that Haliarnassus was the historian's home, and thus we may assume that, for some seven or eight years, that city was the point from which he started and to which he returned. His travels in Asia Minor, in European Greece, and among the islands of the Ægean probably belong to this period, as does also his journey to Susa and Babylon. We are told that when he quitted Haliarnassus on account of the tyranny of Lygdamis, in or about the year 457 B.C., he took up his abode in Samos. That island was an important member of the Athenian confederacy, and in making it his home Herodotus would have

put himself under the protection of Athens. The fact that Egypt was then largely under Athenian influence may have induced him to proceed, in 457 or 456 B.C., to that country. The complete knowledge that he has of the whole of Egypt indicates a stay there of some years, and it was perhaps not till 454 B.C. that he returned to his Samian home. The stories that he had heard in Egypt of Sesostris may then have stimulated him to make voyages from Samos to Colchis, Scythia, and Thrace. When he had seen these countries, he had made acquaintance with almost all the regions which were to be the scene of his projected history, and could apply himself to the task of its composition with the comfortable feeling that he possessed all this local knowledge requisite for graphic and telling description.

After Herodotus had resided for some seven or eight years in Samos, events occurred in his native city which induced him to return thither. The tyranny of Lygdamis had gone on from bad to worse, and at last the citizens rose in rebellion against him, and he was expelled. According to Suidas, Herodotus was himself an actor, and indeed the chief actor, in the enterprise, but no other author confirms this statement, which is intrinsically improbable. It is certain, however, that a revolt broke out, that Lygdamis was dethroned, and that Haliarnassus became a voluntary member of the Athenian confederacy, to which it continued attached. Herodotus would now naturally return to his native city, and enter upon the enjoyment of those rights of free citizenship on which every Greek set a high value. He would also, if he had by this time composed his history, or any considerable portion of it, begin to make it known by recitation among his friends and acquaintance. There is reason to believe that these first attempts to push himself into notice were not received with much favour,—the plotter did not obtain honour in his own country,—his countrymen ridiculed the work which they had been expected to admire, and the disappointed author, chagrined at his failure, precipitately withdrew from his native town, and sought a refuge in Greece proper (about 447 B.C.).

A writer of late date (125–200 A.D.) and of low credit, Lucian of Samosata, in one of his rhetorical pieces, declares that on quitting Haliarnassus Herodotus proceeded straight to Olympia, and finding the quadrennial festival in progress recited his work to the assembled multitude, who were highly delighted with it, and freely expressed their admiration. The statement, however, is improbable, and is rejected by most critics, who point out with reason the unsuitability of the work for recitation before an assemblage of persons from all parts of Greece, and call attention to the suspicious circumstance that the story is first told 600 years after the time of its supposed occurrence. From earlier and better writers we learn that Athens was the place to which the disappointed author betook himself, and that he appealed from the verdict of his countrymen to Athenian taste and judgment. By recitations held in that city he made his work known to the best Grecian intellects, and won such approval that in the year 445 B.C., on the proposition of a certain Anytus, he was voted a sum of ten talents (£2400) by decree of the people. At one of the recitations Thucydides was present with his father, Olorus, and was so moved that he burst into tears, whereupon Herodotus remarked to the father—"Olorus, you see I have a natural enthusiasm for letters."

Athens was at this time the centre of intellectual life, and could boast a galaxy of talent such as has rarely been gathered together either before or since. The stately Pausanias, his clever rival Thucydides the son of Melesandros, the fascinating Aspasia, the eloquent Antiphon, the scientific musician Damon, the divine Phidias, Protagoras the subtle disputant, Zeno the inventor of logic, the jovial yet bitter

Cratinus, the gay Crates, Euripides the master of pathos, Sophocles the most classic even of the ancients, formed a combination of which even Athens might be proud, and which must have claimed the literary aspirant. Accepted into this brilliant society, on familiar terms with all probably, as he certainly was with Olonx, Thucydides, and Sophocles, he cannot but have found his Attic sojourn delightful, and have been tempted, like many another foreigner, to make Athens his permanent home. It is his credit that he did not yield to this temptation. At Athens he must have been a dilettante, an idler, without political lights or duties, a mere literary man. As such he would have soon ceased to be respected in a society where literature was not recognized as a separate profession, where a Socrates served in the infantry, and a Sophocles commanded fleets, and a Thucydides was general of an army, and in Antiphras for a time at the head of the state. Men were not men according to Greek notions unless they were citizens, and Herodotus, aware of this, probably sharing in the feeling, was anxious, having lost his political status at Halicarnassus, to obtain such status elsewhere. At Athens the franchise, jealously guarded at this period, was not to be obtained without great expense and difficulty. Accordingly, in the year 444 B.C., on the scheme of sending a colony to Thurii in Italy being broached by Peucetes, Herodotus was among those who gave in their names, and in the spring of the following year he sailed from Athens to Italy with the other colonists, and became a citizen of the new town.

From this point of his career, when he had reached the age of forty, we lose sight of Herodotus almost wholly. He seems to have made but few journeys, one to Crotona, one to Metapontum, and one to Athens (about 430 B.C.) being all that his work indicates. No doubt he was employed mainly, as Pliny testifies, in retouching and elaborating his general history. He may also have composed at Thurii that special work on the history of Assyria to which he twice refers in his first book, and which is quoted by Aristotle. It has been supposed by many that he lived to a great age, and argued that "the never-to-be-mistaken fundamental tone of his performance is the quiet talkativeness of a highly cultivated, tolerant, intelligent, old man" (Dahlmann). But the indications derived from the later touches added to his work, which form the sole evidence on the subject, would rather lead to the conclusion that his life was not very prolonged. There is nothing in the nine books which may not have been written as early as 430 B.C.; there is no touch which, even probably, points to a later date than 424 B.C. As the author was evidently engaged in polishing up his work to the last, we even promise touches which he does not give, we may assume that he did not much outlive the date last mentioned, or in other words, that he died at about the age of sixty. The predominant voice of antiquity tells us that he died at Thurii, where his tomb was shown in later ages.

In estimating the great work of Herodotus, and his genius as its author, it is above all things necessary to conceive aright what that work was intended to be. It has been called "a universal history," "a history of the wars between the Greeks and the barbarians," and "a history of the struggle between Greece and Persia." But these titles are all too comprehensive. Herodotus, who omits wholly the histories of Phoenicia, Carthage, and Etruria, three of the most important among the states existing in his day, cannot have intended to compose a "universal history," the very idea of which belongs to a later age. He speaks in places as if his object was to record the wars between the Greeks and the barbarians, but as he omits the Trojan war, in which he fully believes, the expedition of the Teuclians and Mysians against Thrace

and Thersaly, the was connected with the Ionian colonization of Asia Minor, and others, it is evident that he does not really aim at embracing in his narrative all the wars between Greeks and barbarians with which he was acquainted. Nor does it even seem to have been his object to give an account of the entire struggle between Greece and Persia. That struggle was not terminated by the battle of Mycale and the capture of Sestos in 479 B.C. It continued for thirty years longer, to the peace of Callias. The fact that Herodotus ends his history where he does shows distinctly that his intention was, not to give an account of the entire long contest between the two countries, but to write the history of a particular war—the great Persian war of invasion. His aim was as definite as that of Thucydides, or Scheller, or Napier, or any other writer who has made his subject a particular war, only he determined to treat it in a certain way. Every partial history requires an "introduction," Herodotus, untrammelled by examples, resolved to give his history a magnificent introduction. Thucydides is content with a single introductory book, forming little more than one eighth of his work, Herodotus has six such books, forming two thirds of the entire composition.

By this arrangement he is enabled to treat his subject in the *grand way*, which is so characteristic of him. Making it his main object in his "introduction" to set before his readers the previous history of the two nations who were the actors in the great war, he is able in tracing this history to bring into his narrative some account of almost all the nations of the known world, and has room to expatiate freely upon their geography, antiquities, manners and customs, and the like, thus giving his work the "universal" character which has been detected in it, and seeming for it, without trenching upon unity, that variety, richness, and fulness which are a principal charm of the best histories, and of none more than his. In tracing the growth of Persia from a petty subject kingdom to a vast dominant empire, he has occasion to set out the histories of India, Media, Assyria, Babylon, Egypt, Syria, Thracians, and to describe the countries and the peoples inhabiting them, their natural productions, climate, geographical position, monuments, &c., while, in noting the contemporaneous changes in Greece, he is led to tell of the various mutations of the Greek race, their colonies, commerce, progress in the arts, revolutions, internal struggles, wars with one another, legislation, religious tenets, and the like. The greatest variety of epical matter is thus introduced, in the propriety of the occasion and the mode of introduction are such that no complaint can be made—the epical is not entangled, enmeshed, or even unpleasantly interrupting the main narrative.

The most important quality of a historian is trustworthiness, for a professed history is of no value unless we can place reliance upon its truth. It has been questioned, both in ancient and in modern times, whether the history of Herodotus possesses this essential requisite. Several ancient writers call his veracity in question, among them the crasse of conscious and intentional untruthfulness. Moderns generally acquit him of this charge, but his severer critics still urge that, from the inherent defects of his character, his credulity, his love of effect, and his loose and inaccurate habits of thought, he was unfitted for the historian's office, and has produced a work of but small historical value. It is impossible, within the limits of an article such as this, to enter fully upon this controversy. Perhaps it may be sufficient to remark that the defects in question certainly exist, and detract to some extent from the authority of the work, more especially of those parts of it which deal with remote periods, and were taken by Herodotus on trust from his informants, but that

they only slightly affect the portions which treat of later times and form the special subject of his history. In confirmation of this view, it may be noted that the authority of Herodotus for the circumstances of the great Persian war, and for all local and other details which come under his immediate notice, is accepted by even the most sceptical of modern historians, and forms the basis of their narratives.

Among the merits of Herodotus as an historian, the most prominent are the diligence with which he has collected the materials for his history, the candour and impartiality with which he has placed his facts before the reader, the political discussions which he displays in the judgment, that he presses upon party leaders, the absence of undue national vanity, and the breadth of his conception of the historian's office, which makes his work a storehouse of diversified knowledge for which the student of antiquity can never be sufficiently grateful. On the other hand, he has no claim to rank as a critical historian, he has no conception of the philosophy of history, no insight into the real causes, that underlie political changes, no power of penetrating below the surface, or even of grasping the real interconnection of the events which he describes. He belongs distinctly to the romantic school, his forte is vivid and picturesque description, the lively presentation to the reader of scenes and actions, characters and states of society, not the subtle analysis of motives, or the power of detecting the undercurrents which sweep events, or the generalising faculty which draws lessons from history and makes the past illumine the darkness of the future.

But it is as a writer that the merits of Herodotus are most conspicuous and most unquestioned. "O that I were in a condition," says Lucian, "to resemble Herodotus, if only in so much measure! I by no means say in all his gifts, but only in some single point, as, for instance, the beauty of his language, or its harmony, or the natural and peculiar glow of the Ionic dialect, or his fulness of thought, or by whatever name those thousand beauties are called which to the deceiver of his imitator are united in him." Cicero calls his style "copious and polished," Quintilian, "sweet, pure, and flowing," Longinus says he was "the most Homeric of historians," Dionysius, his countrymen, profess him to Thucydides, and regards him as combining in an extraordinary degree the excellences of sublimity, beauty, and the true historical method of composition. Moderns are almost equally complimentary. "The style of Herodotus," says one, "is universally allowed to be remarkable for its harmony and sweetness." "The charm of his style," argues another, "has so dazzled men as to make them blind to his defects." Various attempts have been made to analyse the nature of the charm which is so universally felt, but it may be doubted whether any of them are very successful, whether the aroma of the flower does not evaporate in the critic's alembic. All, however, seem to agree that among the qualities for which the style of Herodotus is to be admired are simplicity, freshness, naturalness, and harmony of rhythm. Master of a form of language peculiarly sweet and euphonical, and possessed of a delicate ear which instinctively suggested the most musical arrangement possible, he gives his sentences, without art or effort, the most agreeable flow, is never abrupt, never too diffuse, much less prolix or wearisome, and being himself simple, fresh, *naïf* (if we may use the word), honest, and somewhat quaint, he delights us by combining with this melody of sound simple, clear, and fresh thoughts, perspicuously expressed, often accompanied by happy turns of phrase, and always manifestly the spontaneous growth of his own fresh and unobscured mind. Reminding us in some respects of the quaint medieval writers, Froissart and Philippe de Comines, he greatly excels them, at once in the beauty of his language and the art with which he has com-

bined his heterogeneous materials into a single perfect harmonious whole.

As might have been expected from its excellence, the history of Herodotus has been translated by many persons, and into many languages. About 1550, at the time of the revival of learning, a Latin version was made and published by Laurentius Valla. This was revised in 1587 by Heinschius, and accompanied the Greek text of Herodotus in many editions. The first complete translation of Herodotus into the English one of Littlebury, published in 1787. This was followed in 1788 by the French translation of Leclercq, a valuable work, accompanied by copious notes, and, especially, the second English translation of his work, that of Leitch. His first edition, in 1791, was considerably very defective, the second, in 1806, still left much to be desired. A good German translation, but without note or comment, was brought out by Fritschel Lange at Berlin in 1811. Andrew Mastrick, a native of Ohio, published an Italian version in 1820. In 1822 Auguste Moët endeavored to improve on Leitch, and in 1828-29 Dr Adolf Schöll brought out a German translation with copious notes (now ed., 1855), which but to some extent improved the work of Lange. About the same time a new English version was made by Mr Henry Taylor (London, 1829). Finally, in 1858-60, the history of Herodotus was translated by Canon Rawlinson, assisted in the copious notes and appendices accompanying the work by Sir Osbert Wilkinson and Sir Henry Rawlinson. More recently we have translations in German by E. H. Stettin (Stuttgart, 1857) and Fritz Gieseler (Gießen, 1875), in French (Garnier, 1857) and J. Albert (1864), and in Italian by Ricci (Turin, 1871-72), Grandi (1871, 1872), and Butini (Naples, 1871-72). A Swedish translation by E. Crnkeldt was published at Stockholm in 1867.

The principal editions of the Greek text of Herodotus are the following:—*Herodoti Historia*, ed. Schweighauser, 6 vols. 8vo, Strasbourg, 1816; *Herodoti Hellenicae Historiarum libri IX*, ed. Gaisford, Oxford, 1840; *Herodotus, with a Commentary*, by J. W. Blakesley, B. D., 2 vols. 8vo, London, 1855; *Herodoti Historiæ*, ed. Blais, 2 vols. 8vo, Leipzig, 1856-61, 2d ed. *Herodoti Historiarum*, ed. Abicht, 2 vols. 8vo, Leipzig, 1860, and *Herodoti Historiarum*, ed. H. Stein, 2 vols., 1860-71. Among works of value illustrative of Herodotus may be mentioned *Herodoti Historiæ*, ed. Heinschius, Dijon, 1718; *Reinold, Geography of Herodotus*, London, 1800; *Nicolaï, Geography of Herodotus and Strabo*, Eng. trans., Oxford, 1850; *Reinach, Herodote, ou l'usage du verbe*, Paris, 1850; *Altort, 1825, 2d ed., Quæstiones Herodoteæ*, 1 vol. 8vo, 1841; *Konrad, Egypt of Herodotus*, London, 1841; *Murr, Litteratur der Græci*, vol. iv., London, 1862; *Abicht, Ueberblick über den Herodotischen Dialect* (Leipzig, 1859, 2d ed. 1874); and *De eodem Herodoti fide ac auctoritate* (Nürnberg, 1866). *Melander, De anacronismis Herodoti* (Lund, 1886). *Matzke, "Über die Glaubwürdigkeit des geograph. Angaben Herodoti über Asien," in Germania*, v. Bismarck, *Zur europäischen Forschung Herodoti* (Vienna, 1875, reprinted from the *Sitzungsberichte der Vienna Acad.*); *Melander, Quæstiones grammaticæ de dialecto Herodoti* (Leipzig, 1876); A. Kirchhoff, *Über die Entstehung und den Herodotischen Geschichtssinn* (Berlin, 1878); and Ad. Bætz, *Herodoti Biographie* (Vienna, 1878). For notices of current literature see *Bisleri's Jahresbericht*. Students of the original may also consult with advantage the Lexicons of *Reinhold Fritsch* (Oxford, 1817) and of *Schweighauser* (London, 1844).

HEROLD, LOUIS JOSEPH FREDERICK (1791-1855), French musician, was born at Paris, Jan. 28, 1791, the son of François Joseph Herold, an accomplished pianist, who, however, did not at first wish his son to adopt the musical profession. It was indeed not till after his father's death that Herold in 1806 entered the Paris conservatoire, where he studied under Catel and Méhul, one of the leading composers of the time, by whose teaching his pupil profited soon and permanently. In 1812 he gained the grand prix de Rome (a travelling scholarship awarded by the French Government to the best pupils of the conservatoire), and accordingly started for Italy, where he remained till 1815, and composed a symphony, a cantata, and several pieces of chamber music. It was also during his stay in Italy that Herold for the first time ventured on the stage with the opera *Le Comte de Yver*, first performed at Naples in 1815 with moderate success. Returning to Paris he had the good fortune to be invited by Bérlioz to participate in the composition of an opera called *Charles de France*, performed in 1816, and soon followed by Herold's first French opera, *Les Rosières* (1817), which was received very favourably. Of the numerous dramatic works which Herold produced for

the next fifteen years in rapid succession it is unnecessary to give a detailed account. Only the names of some of the more important may be mentioned here.—*Le Clochette* (1817), *L'Adieu mort et vivant* (1820), *Marie* (1826), and the ballets *La Fille mal Gardée* (1828) and *La Belle au bois dormant* (1839). Hérold also wrote a vast quantity of piano-forte music of a more or less ephemeral kind, in spite of his time being much occupied by his duties as accompanist at the Italian opera in Paris. In 1831 he produced one of the two works which have given immortality to his name, the romantic opera *Zampa*, which has met with immense success not only in France but also in Germany, where it has kept the stage till the present day, and is considered Hérold's masterpiece. In France that eminence is justly accorded to the *Le Pré aux Clercs* (first performance December 15, 1832), in every way a representative work of the French school, in which French spirit and French chivalry find their most perfect embodiment. Grace, liveliness, and true dramatic spirit are Hérold's best qualities, and secure him a prominent place amongst the composers of *opéra comique*, in the more refined sense which has been lost by most composers of modern France. Hérold died January 19, 1833, of the lung disease from which he had suffered for many years, and the effects of which he accelerated by incessant work.

HERON, or HERO, a mathematician and natural philosopher of Alexandria, was the pupil of Ctesibius, and flourished probably about a century or a century and a half before Christ. His name has been preserved in the well-known experiment of Hero's fountain, in which, by means of condensed air, water is made to spring from a jet in a continuous stream. Several of Heron's writings are entirely lost, and of those that remain some have never been printed. His most valuable work is that on *Pneumatics*, in which are given his experiments on the elasticity of air and of steam. His *Mechanics* and *Barulous* treat of the subjects which would now be comprised in an elementary book on dynamics. At the end of his *Catoptrics* or *Dioptrics*, which are probably the same, occurs Heron's solution of the ancient and much discussed problem to find two mean proportionals between two given straight lines. *Chairobaltica*, *Cambistria*, *Camarica*, *Automata*, are the titles of some of his other physical works. His mathematical works (see Hultsch's *Heronis Alexandrini Geometricorum et Stereometricorum Reliquiae*, Berlin, 1864) are very fragmentary, and it is difficult to determine whether several of them are not to be attributed to later and anonymous writers. Heron seems to have been the first to show how the area of a triangle may be found from its three sides. See two papers by Vincent and Boncompagni in *Bullettino di bibliogr. e di storia delle scienze matematiche*, i. fascio, iv.

HERON, called the younger, to distinguish him from his namesake of Alexandria, was, like him, a mathematician and natural philosopher. By some he is supposed to have flourished in the first half of the 7th century A.D.; by others, with more probability, to have lived at Constantinople in the 10th century. He wrote a treatise on *Bestwing Engines* which still exists, and another on the *Construction of Sundials*, which is now lost. Some mathematical writings assigned to him should perhaps be referred to Heron the elder (see *Mémoires Présentés à l'Académie des Inscriptions*, 1^{re} série, tome iv., Paris, 1854).

HERON—French, *Héron*; Italian, *Aghirone*, *Avirone*; Latin, *Ardea*; Greek, *Ardeios*; Anglo-Saxon, *Eragra*; Icelandic, *Haggr*; Swedish, *Herger*; Danish, *Heir*; German, *Heiger*, *Reiker*; Heerygon; Dutch, *Reiger*—a long-necked, long-winged, and long-legged bird, the representative of a very natural group, the *Ardeidae*, which through the neglect or ignorance of ornithologists has been for many years encumbered by a considerable number of alien forms,

belonging truly to the Cranes, *Gruidæ* (see vol. vi. p. 546), and *Storks*, *Ciconiidae*, whose structure and characteristics are wholly distinct, however much external resemblance some of them may possess to the Herons. Eliminating these intruders, it is difficult or even impossible to estimate with any accuracy the number of species of *Ardeidae* which exist. Professor Schlegel in 1863 enumerated 61, besides 5 of what he terms "conspicuous," as contained in the collection at Leyden (*Mus. des Pays Bas*, *Ardeæ*, 64 pp.),—on the other hand, G. R. Gray in 1871 (*Hand-list*, &c., iii. pp. 26-34) admitted above 90, while Dr. Reichenow (*Journal für Ornithologie*, 1877, pp. 232-275) recognizes 67 as known, besides 15 "subspecies" and 3 varieties, arranging them in 8 genera, *Nycticorax*, *Recurvirostra*, and *Ardea*, with 17 subgenera. But it is difficult to separate the family, with any satisfactory result, into genera, if structural characters have to be found for these groups, for in many cases they run almost insensibly into each other—though in common language it is easy to speak of Herons, Egrets, Bitterns, Night-Herons, and Boatbills. With the exception of the last, Professor Schlegel retains all the

FIG. 1.—HERON.

genus *Ardea*, dividing it into eight sections, the names of which may perhaps be Englished—Great Herons, Small Herons, Egrets, Semi-egrets, Rail-like Herons, Little Bitterns, Bitterns, and Night-Herons. It may be expedient here to adopt this arrangement, though the present writer would guard himself against being supposed to give it more than partial and provisional assent.

The common Heron of Europe, *Ardea cinerea* of Linnaeus, is universally allowed to be the type of the family, and it may also be regarded as that of Professor Schlegel's first section. The species inhabits suitable localities throughout the whole of Europe, Africa, and Asia, reaching Japan, many of the islands of the Indian Archipelago, and even Australia. Though by no means so numerous as formerly in Britain, it is still sufficiently common to render a description of it almost unnecessary,¹ and there must be few persons who have not seen it rising slowly from some river-side or marshy flat, or passing overhead in its lofty and

¹ In many parts of England it is generally called a "Hermes" being a corruption of "Heronsway," which, as Professor Skeat states (*Etymol. Dictionary*, p. 324), is a perfectly distinct word from "Heronshaw," commonly confounded with it. The further corruption of "Hermes" into "handaw," as in the well-known proverb, was easy in the mouth of men to whom hawking the Heronsway was unfamiliar.

leisurely flight on its way to or from its daily haunts; while they are many who have been entertained by watching it as it sought its food, consisting chiefly of fishes (especially eels and flounders) and amphibians—though young birds and small mammals come not amiss—wading midge in the shallows, swimming occasionally when out of its depth, or standing motionless to strike its prey with its formidable and sure beak. When sufficiently numerous the Heron breeds in societies, known as Heronries, which of old time were protected both by law and custom in nearly all European countries, on account of the sport their tenants afforded to the falconer. Of late years, partly owing to the withdrawal of the protection they had enjoyed, and still more, it would seem, from agricultural improvement, which, by draining meres, fens, and marshes, has abolished the feeding-places of a great population of Herons, many of the larger Heronries have broken up—the birds composing them dispersing to neighbouring localities and forming smaller settlements, most of which are hardly to be dignified by the name of Heronry, though commonly accounted such.

Thus the number of so-called Heronries in the United Kingdom, and especially in England and Wales, has become far greater than formerly, but no one can doubt that the number of Herons has dwindled. Mr Harting, after being at great pains to collect statistics on the subject, gave, in 1873 (*Zoologist*, s. s. pp. 3201-3272; with additions and corrections, pp. 3404-3407), a list of those existing in the three kingdoms, more than 200 in number, of which a little over one-half are in England and Wales, more than 50 in Scotland, and nearly 50 in Ireland. The sites chosen by the Heron for its nest very greatly. It is generally built in the top of a lofty tree, but not unfrequently (and this seems to have been much more usual in former days) near or on the ground among rough vegetation, or on an island in a lake, or again on a rocky cliff of the coast. It commonly consists of a huge mass of sticks, often the accumulation of years, lined with twigs, and in it are laid from four to six sea-green eggs. The young are clothed in soft flax-coloured down, and remain in the nest for a considerable time, therein differing remarkably from the "pipers" of the Crane, which are able to run almost as soon as they are hatched. The first feathers assumed by young Herons in a general way resemble those of the adult, but the fine leaden-grey back, the pure white breast, the black throat-streaks, and especially the long pendulous plumes, which characterize only the very old birds, are most beautiful in the cocks, are subsequently acquired. The Heron measures about 3 feet from the bill to the tail, and the expanse of its wings is sometimes not less than 6 feet, yet it weighs only between 3 and 4 lb.

Large as is the common Heron of Europe, it is exceeded in size by the Great Blue Heron of America, *Ardea herodias*, which generally resembles it in appearance and habits, and both are smaller than the *A. sumatrana* or *A. typhos* of India and the Malay Archipelago, while the *A. goliath*, of wide distribution in Africa and Asia, is the largest of all. The Purple Heron, *A. purpurea*, as a well-known European species having a great range over the Old World, also deserves mention here. Of the species included in Professor Schlegel's second section, little need now be said. They inhabit the tropical parts of Africa, Australasia, and America. The Egrets, forming his third group, require more notice, distinguished as they are by their pure white plumage, and, when in breeding-dress, by the beautiful dorsal tufts of decomposed feathers that ordinarily droop over the tail, and are so highly esteemed as ornaments by Oriental magnates. The largest species is *A. occidentalis*, only known apparently from Florida and Cuba; but one not much less, the Great Egret, *A. alba*, belongs to the Old World, breeding regularly in south-eastern Europe,

and occasionally straying to Britain. A third, *A. egretta*, represents it in America, while much the same may be said of two smaller species, *A. garzetta*, the Little Egret of English authors, and *A. candidissima*; and a sixth, *A. intermedia*, is common in India, China, and Japan, besides occurring in Australia. The group of Semi-egrets, containing some nine or ten forms, among which the Buff-backed Heron, *A. bubulcus*, is the only species that is known to have occurred in Europe, is hardly to be distinguished from the last section except by their plumage being at certain seasons varied in some species with slaty-blue and in others with rufous. The Rail-like Herons form Professor Schlegel's next section, but it can scarcely be satisfactorily differentiated, and the epithet is misleading, for its members have no Rail-like affinities, though the typical species, which inhabits the south of Europe, and occasionally finds its way to England, has long been known as *A. valisoides*.¹ Nearly all these birds are tropical or sub-tropical. Then there is the somewhat better defined group

FIG. 1.—BITTERN.

of Little Bitterns, containing about a dozen species—the smallest of the whole family. One of them, *A. minima*, though very local in its distribution, is a native of the greater part of Europe, and has bred in England. It has a close counterpart in the *A. exilis* of North America, and is represented by three or four forms in other parts of the world, the *A. pusilla* of Australia especially differing very slightly from it. Ranged by Professor Schlegel with these birds, which are all remarkable for their skulking habits, but more resembling the true Herons in their nature, are the common Green Bittern of America, *A. virescens*, and its very near ally the African *A. atricapilla*, from which last it is almost impossible to distinguish the *A. fuscica*, of wide range throughout Asia and its islands, while other species, less closely related, occur elsewhere as *A. flavicollis*, —one form of which, *A. gouldi*, inhabits Australia.

The true Bitterns, forming the genus *Botaurus* of most authors, seem to be fairly separable, but more perhaps on account of their wholly nocturnal habits and correspondingly adapted plumage than on strictly structural grounds, though some differences of proportion are observable. The

¹ It is the "Squacco-Heron" of modern British authors—the distinctive name, given "Squacco" by Willughby and Ray from *Aldrovandus*, having been misapplied by Latham.

common Bittern of Europe, *B. stellaris*, was formerly an abundant bird in many parts of Britain; but, since the reclamation of the bogs and fens it used to inhabit, it is become only an irregular visitant,—though not a winter passes without its appearing in some numbers, when its uncommon aspect, its large size, and beautifully pencilled plumage cause it to be regarded as a great prize by the lucky gun-bearer to whom it falls a victim. Its value as a delicacy for the table, once so highly esteemed, has long vanished. The old fable of this bird inserting its beak into a reed or plunging it into the ground, and so causing the booming sound with which its name will be always associated, is also exploded, and nowadays indeed so few people in Britain have ever heard its loud and awful voice, which seems to be uttered only in the breeding-season, and is therefore unknown in a country where it no longer breeds,¹ that incredulity as to its booming at all has in some quarters succeeded the old belief in this as in other reputed peculiarities of the species. The Bittern is found from Ireland to Japan, in India, and throughout the whole of

FIG. 8.—Boatbill.

Africa—suitable localities being, of course, understood. Australia and New Zealand have a kindred species, *B. pectoratus*, and North America a third, *B. magdalenae* or *B. lentiginosus*. The former is said to bellow like a bull, but authorities differ as to the vocal powers of the latter,² which has several times wandered to Europe, and is distinguishable by its smaller size and uniform greyish-brown primaries, which want the tawny bars that characterize *B. stellaris*. Nine other species of Bitterns from various parts of the world are admitted by Professor Schlegel, but some of them should perhaps be excluded from the genus *Botaurus*.

Of the Night-Herons the same author recognizes six species, all of which may be reasonably placed in the genus *Nycticorax*, characterized by a shorter beak and a few other peculiarities, among which the large eyes deserve mention. The first is *N. grisea*, a bird widely spread over the Old World, and not unfrequently visiting England, where it would undoubtedly breed if permitted. Professor Schlegel unites with it the common Night-Heron of America; but

this, though very closely allied, is generally deemed distinct, and is the *N. naevius* or *N. gardneri* of most writers. A clearly different American species, with a more southern habitat, is the *N. violacea* or *N. cayennensis*, while others are found in South America, Australia, some of the Asiatic Islands, and in West Africa. The Galapagos have a peculiar species, *N. pauper*, and another, so far as is known, peculiar to Rodriguez, *N. megalophthalmus*, existed in that island at the time of its being first colonized, but is now extinct.

The Boatbill, of which only one species is known, seems to be merely a Night-Heron with an exaggerated bill,—so much widened as to suggest its English name,—but has always been allowed generic rank. This curious bird, the *Canomoma cochlearia* of most authors, is a native of tropical America, and what is known of its habits shows that they are essentially those of a *Nycticorax*.³

Bones of the common Heron and Bittern are not uncommon in the peat of the East-Anglian fens. Remains from Sansan and Langy in France have been referred by M. Alphonse Milne-Edwards to Herons under the names of *Ardea perplexa* and *A. formosa*; a tibia from the Miocene of Steinheim by Dr Fraas to an *A. similis*, while Professor Owen recognized a portion of a sternum from the London Clay as most nearly approaching this Family.

It remains to say that the Heron forms part of Professor Huxley's section *Pelargomorphæ*, belonging to his larger group *Demognathæ*, and to draw attention to the singular development of the patches of "powder-down" which in the family *Ardeidae* attain a magnitude hardly to be found elsewhere. Their use is utterly unknown. (A. N.)

HEROPHILUS. See ANATOMY, vol. i. p. 801-2.

HERRERA, FERNANDO DE (1534-1597), lyrical poet, born at Seville in 1534. Although an ecclesiastic, he addressed his verses to an Andalusian lady, said to have been the countess of Gelves, under different names; but his love was as Platonic as Petrarch's, and served only to lend additional beauty and tenderness to his poems. Herrera has been celebrated in a sonnet by Cervantes; and his poems were taken as models by the later poet, Lope de Vega. He died at Seville in 1597. Flourishing at a time when the Castilian language was not yet ripe for the higher lyrical efforts, Herrera endeavoured to remedy the defects of his native tongue by expelling from poetry the more vulgar and trivial words, by introducing words in their place from Greek, Latin, and Italian, and by employing unfamiliar inflexions and inverted constructions so as to approach more nearly the model of the classical tongues. His system, however, was theoretical and artificial, and not inspired by any genuine impulse of taste, so that in many instances where he strives to be elevated and correct, he succeeds only in being affected and formal.

Herrera published his critical views in 1580, in able notes to the works of Garcilaso, whose Italian style he followed in a volume of poems which appeared in 1589. Of these the sonnets are poor, the elegies good, and the sixteen cantatas or odes half of all. The finest of these last are perhaps the two on the battle of Lepanto and on the overthrow of Sebastian of Portugal. The Pindaric ode on sleep has been frequently praised. Pacheco, the painter, published additional poems of Herrera in 1610; and the poet's name is mentioned in the fourth and fifth volumes of his *Poesías Castellanas*, in 1608. *The Battle of the Giants*, *The Rope of Proserpine*, *The Andalus*, and *The Loves of Laurindo and Ceyra* are among the titles of longer poems of Herrera which are now lost. Of his prose works the chief are the *Relación de la Guerra de Chile y batalla de Lepanto*, 1672; and the *Vida y muerte de Juan de Mariana*, 1693, translated from Stapleton's Latin *Life of the Three Thomases*. His *History of Spain* fills the time of *Cherica F.*, said by Hjelte to have been completed about 1590, has not come down to our time.

¹ The very wonderful Shoo-hoo (*Baleniceps*) has been regarded by many authorities as allied to *Canomoma*, but there can be little doubt that it is more nearly related to the genus *Scopus* belonging to the Storks. The Sun-Bittern (*Eurypyga*), by some systematicists considered to belong to the *Ardeidae*, would appear to have greater affinity to the *Rallidae*, if it does not form a Family of itself.

¹ The last-recorded instance of the Bittern breeding in England was in 1828, as mentioned by Mr Stevenson (*Birds of Norfolk*, ii. p. 164). All the true Bitterns, so far as is known, lay eggs of a light olive-brown colour.

² Richardson, a most accurate observer, positively asserts (*Poisonous Birds of America*, ii. p. 374) that its booming exactly resembles that of its Old-World congener, but American ornithologists seem only to have heard the croaking note it makes when disturbed.

HERRERA, FRANCISCO (1576-1556), sui nomencl el Viejo (the old), historical and fresco painter, studied under Luis Penabazca in Seville, his native city, where he spent the most of his life. Although so rough and coarse in manners that neither scholar nor child could remain with him, the great talents of Herrera, and the promptitude with which he used them, brought him abundant commissions. He was also a skilful worker in bronze, an accomplishment that led to his being charged with earning base money. From this accusation, whether true or false, he sought sanctuary in the Jesuit college of San Hermenegildo, which he adorned with a fine picture of his patron saint Philip IV, on his visit to Seville in 1624, having seen this picture, and learned the position of the artist, pardoned him at once, warning him, however, that such ploys as his should not be degenerated. In 1650 Herrera removed to Madrid, where he lived in great honour till his death in 1656. Herrera was the first to extinguish the timid manner of the old Spanish school of painting, and to imitate the free, vigorous touch and style which reached such perfection in Velazquez, who had been for a short time his pupil. His pictures are marked by an energy of design and freedom of execution quite in keeping with his bold, tough character. He is said to have used very long brushes in his painting, and it is also said that, when pupils failed, his servant used to dash the colour on the canvas with a broom under his directions, and that he worked them up into his designs before they dried. The drawing in his pictures is correct, and the colouring original and skilfully managed, so that the figures stand out in striking relief. What has been considered his best oil-work, the Last Judgment, in the church of San Donato at Seville, is an original and striking composition, showing in its treatment of the nude how ill-founded the common belief was that Spanish painters, through ignorance of anatomy, understood only the draped figure. Perhaps his best fresco is that on the dome of the church of San Buenaventura, but many of his frescoes have perished, some by the effects of the weather, and others by his artist's own carelessness in preparing his surfaces. He has, however, preserved several of his own designs in etchings. For his novel works Herrera often chose such humble subjects as fairs, carnivals, ale-houses, and the like.

See Stirling's *Annals of the Artists of Spain*, 3 vols, 1818.

HERRERA, FRANCISCO (1622-1685), surnamed el Mozo (the young), historical and fresco painter, son of the subject of last notice, was also a native of Seville. Unable to endure his father's cruelty, the younger Herrera, seizing what money he could find, fled to Rome. There, instead of devoting himself to the antiquities and the works of the old Italian masters, he gave himself up to the study of architecture and perspective, with the view of becoming a fresco-painter. He did not altogether neglect oil-work, but became renowned for his pictures of still life, flowers, and fruit, and from his skill in painting fish was called by the Italians *Lo Spingueludo degli pesci*. In later life he painted portraits with great success. He returned to Seville on hearing of his father's death, and in 1660 was appointed subdirector of the new academy there under Murillo. His vanity, however, brooked the superiority of no one, and throwing up his appointment he went to Madrid. There he was employed to paint a San Hermenegildo for the barefooted Carmelites, and to decorate in fresco the roof of the choir of San Felipe el Real. The success of this last work procured for him a commission from Philip IV to paint in fresco the roof of the Atocha church. He chose as his subject for this the Assumption of the Virgin. Soon afterwards he was rewarded with the title of painter to the king, and was appointed superintendent of the royal buildings. He died at Madrid in 1685. Herrera, el Mozo was of a somewhat similar temperament to his father, and

offended many people by his inordinate vanity and suspicious jealousy. His pictures are inferior to the older Herrera's both in design and in execution, but in some of them traces of the vigour of his father, who was his first teacher, are visible. He was by no means an unskilful colourist, and was especially master of the effects of chiaroscuro. As his best picture St Edmund Head in his *Handbook* names his San Francisco, in Seville Cathedral. An elder brother, known as Herrera el Rubio (the ruddy), who died very young, gave great promise as a painter.

See Stirling's *Annals of the Artists of Spain*, 3 vols, 1818.

HERRERA Y TORDESILLAS, ANTONIO DE (1549-1626), Spanish historian, was born in 1549, at Ouelma, in the province of Segovia in Spain. His father, Rodrigo de Tordesillas, and his mother, Agnes de Herrera, were both of good family. After studying for some time in his native country, Herrera proceeded to Italy, and there became secretary to Vespasiano Gonzaga, with whom, on his appointment as viceroy of Navarre, he returned to Spain. Gonzaga, sensible of his secretary's abilities, commended him on his death-bed to Philip II of Spain, and that monarch, no less discerning, appointed Herrera first historiographer of the Indies, and one of the historiographers of Castile. Placed thus in the enjoyment of an ample salary, Herrera devoted the rest of his life to the peaceful pursuit of literature, retaining his offices till the reign of Philip IV, by whom he was appointed secretary of state, a short while, however, before his death, which took place at Madrid on March 29, 1626. Of Herrera's writings, the most valuable is his *Historia General de los Iluchos de los Castellanos en las Islas y Tierra Firme del Mar Oceano* (Madrid, 1601-15, 4 vols fol), a work which relates the history of the Spanish-American colonies from 1492 to 1554. The author's official position gave him access to the state papers and to other authentic sources not attainable by other writers, while he did not scruple to borrow largely from other MSS, especially from that of Las Casas. He used his facilities carefully and judiciously, and the result is a work on the whole accurate and unperplexed, and quite indispensable to the student either of the history of the early colonies, or of the institutions and customs of the aboriginal American peoples. Although it is written in the form of annals, mistakes are not wanting, and several glaring anachronisms have been pointed out by Quintana. "If" to quote Dr Robertson, "by attempting to relate the various occurrences in the New World in a strict chronological order, the arrangement of events in his work had not been rendered so perplexed, disconnected, and obscure that it is an unpleasant task to collect from different parts of his book and piece together the detached already of a story, he might justly have been ranked among the most eminent historians of his country."

Herrera's other works are the following—*Historia de la Sucesión en España e Inglaterra en quarenta y quatro años que vivió la reyna Maria Estuarda* (Madrid, 1589), *Cinco Libros de la Historia de Portugal, y Conquista de las Indias de la Africa, 1582 y 1584* (ib, 1591), *Historia de la Sucesión en Francia, 1585-1594* (ib, 1598), *Historia General del Mundo del tiempo del Señor Rey Don Felipe II, desde 1519 hasta su muerte* (ib, 1601-12, 8 vols fol), *Práctico, Testamento, y Suma de las leyes de las monarquías de Aragón* (ib, 1610), *Compendio de los Iluchos de los Españoles, Franceses, y Portugueses en Italia, &c, desde 1281 hasta 1550* (ib, 1624, fol).

HERRICK, RONNIE (1691-1674), English poet, was born in Chopsade, London, and baptized on the 24th of August 1691. He was the seventh child of Nicholas Herriek, goldsmith, of the city of London, who died in 1692, under suspicion of suicide. The children were brought up by their uncle, Sir William Herriek, one of the richest goldsmiths of the day, to whom in 1697 Robert was bound apprentice. In 1618 he proceeded to Cambridge, and it was no doubt between these dates that the young poet was introduced to that circle of wit which he

was afterwards to adorn. He seems to have been present at the first performance of *The Alchemist* in 1610, and it was probably about this time that Ben Jonson adopted him as his poetical "son." He entered the university as fellow-commoner of St John's College, and he remained there until, in 1616, upon taking his degree, he removed to Trinity Hall, in 1620 he became master of arts. From this date until 1629 we entirely lose sight of him; it has been variously conjectured that he spent these nine years preparing for the ministry at Cambridge, or in much looser pursuits in London. In the latter year his mother died, and, taking orders, he was presented to the rural living of Dean Prior, not far from Totnes in Devonshire. He entered upon this new career on October 2, 1629, being in his thirty-ninth year. At Dean Prior he resided quietly until 1648, when he was ejected by the village was dull and remote and he felt very bitterly that he was cut off from all literary and social associations, but soon the quiet existence in Devonshire soothed and delighted him. He was pleased with the rural and semi-pagan customs that survived in the village, and in some of his most charming verses he has immortalized the morris dances, wakes, and quintains, the Christmas mummers and the Twelfth Night revellings, that diversified the quiet of Dean Prior. Herrick never married, but lived at the vicarage surrounded by a happy family of pets, and tended by an excellent old servant named Eudene Baldwin. His first appearance in print was in some verses he contributed to *A Description of the King and Queen of France*, in 1635. In 1640 a volume of *Mr's Recreations* contained sixty-two small poems afterwards acknowledged by Herrick in the *Hesperides*, and one not reprinted until our own day. These partial appearances make it probable that he visited London from time to time. We have few hints of his life as a clergyman. Anthony Wood says that Herrick's sermons were florid and witty, and that he was "beloved by the neighbouring gentry." A very aged woman, one Dorothy King, stated that the poet once threw his sermon at his congregation, cursing them for their inattention. The same old woman recollected his favourite pig, which he taught to drink out of a tankard. In 1648 he published his celebrated collection of lyrical poems, entitled *Hesperides*, or the *Works both Imitant and Divine of Robert Herrick*, only a few weeks, it would seem, after his ejection from his living by the Puritans. That he was reduced to great poverty in London has been stated, but Dr Gossett shows this to be very unlikely. In August 1662 Herrick returned to Dean Prior, supplanting his own successor, Dr John Syme. He died in his eighty-fourth year, and was buried at Dean Prior, October 15, 1634. A monument was erected to his memory in the parish church in 1667.

As a pastoral lyric Herrick stands first among English poets. His genius is limited in scope, and comparatively unambitious, but in its own field it is unrivalled. His tiny poems—and of the thirtie hundred that he has left behind him not one is long—are like jewels of various value, heaped together in a casket. Some are of the purest water, radiant with light and colour, some were originally set in false metal that has tarnished, some were rude and repulsive from the first. Out of the unarranged, heterogeneous mass the student has to select what is not worth reading, but, after he has cast aside all the rubbish, he is astonished at the amount of excellent and exquisite work that remains. Herrick has himself summed up, very correctly, the themes of his sylvan muse when he says—

I sing of brooks, of blossoms, birds and bowers,
Of April, May, of June and July flowers;
I sing of May-poles, black-curtain balls, wakes,
Of bridle-grooms, brides, and of their bridal cakes

He saw the picturesqueness of English homely life as no one before him had seen it, and he described it in his verse with a certain purple glow of Arcadian romance over it in tones of immortal vigour and freshness. His love poems are still more beautiful, the best of them have an ardour and tender sweetness which give them a place in the fore front of modern lyrical poetry, and remind us of what was best in Horace and in the poets of the Greek anthology.

After suffering complete extinction for more than a century, the fame of Herrick was revived by Mr Nichols (Bibliotheca Urbana), who introduced his poems to the readers of the *Gentleman's Magazine* of 1796 and 1797. Dr Diike followed in 1798 with considerable enthusiasm. By 1810 interest had so far revived in the forgotten poet that Dr Nott ventured to print a selection from his poems, which attracted the favourable notice of the *Quarterly Review*. In 1822 the *Hesperides* and the *Noble Numbers* were for the first time edited by Mr T. Matland, afterwards Lord Dunsinon. Other editions followed in 1859, 1844, 1848, 1850, 1852, and 1859. A more complete collection, by Mr W. C. Wright, was brought out in 1869. In 1876 followed Dr Gossett's exhaustive and authoritative edition in three vols., and in 1877, under the title of *Chrysomela*, a very elegant selection by Mr F. T. Ugvalde, with a preface by every. There are therefore few English poets of the 17th century whose writings are now more accessible to every class of readers than those of Herrick.

HERRING (*Clupea harengus*, *Haring* in German, *Le Hareng* in French, *Sill* in Swedish), a fish belonging to the genus *Clupea*, of which more than sixty different species are known in various parts of the globe. The sprat, pilchard or saury, and shad are species of the same genus. Of all sea fishes *Clupea* are the most abundant, far although other genera may compose a greater variety of species, they are far surpassed by *Clupea* with regard to the number of individuals. The majority of the species of *Clupea* are of greater or less utility to man; it is only a few tropical species that acquire, probably from their food, highly poisonous properties, so as to be dangerous to persons eating them. But no other species equals the Common Herring in importance as an article of food or commerce. It inhabits in incredible numbers the German Ocean, the northern parts of the Atlantic, and the seas north of Asia. The herring inhabiting the corresponding latitudes of the North Pacific is another species, but most closely allied to that of the eastern hemisphere. Formerly it was the general belief that the herring inhabits the open sea in close to the Arctic Circle, and that it migrates at certain seasons towards the northern coasts of Europe and America. This view has been proved to be erroneous, and we now know that this fish lives throughout the year in the vicinity of our shores, but at a greater depth, and at a greater distance from the coast, than at the time when it approaches land for the purpose of spawning.

Herrings are readily recognised and distinguished from the other species of *Clupea* by having an entire patch of very small teeth on the vomer (that is, the centre of the palate). In the dorsal fin they have from 17 to 20 rays, and in the anal fin from 16 to 18, there are from 53 to 69 scales in the lateral line, and invariably 56 vertebrae in the vertebral column. They have a smooth gill cover, without those radiating ridges of bone which are so conspicuous in the pilchard and other *Clupea*. The sprat cannot be confounded with the herring, as it has no teeth on the vomer, and only 47 or 48 scales in the lateral line.

Herrings grow very rapidly, according to Mr A. Meyer's observations, they attain a length of from 17 to 18 mm. during the first month after hatching, 31 to 36 mm. during the second, 45 to 50 mm. during the third, 53 to 61 mm. during the fourth, and 65 to 72 mm. during the fifth. The size which they finally attain and their general condition depend chiefly on the abundance of food (which consists of crustaceans and other small marine animals), on the temperature of the water, on the season at which they have been hatched, &c. Their usual size is

about 12 inches, but in some particularly suitable localities they grow to a length of 15 inches, and instances of specimens measuring 17 inches are on record. In the Baltic, where the water is gradually losing its saline constituents, thus becoming less adapted for the development of marine species, the herring continues to exist in large numbers, but as a dwarfed form, not growing either to the size or to the condition of the North-Sea herring. The herring of the American side of the Atlantic is specifically identical with that of Europe. A second species (*Clupea leachii*) has been supposed to exist on the British coast, but it comprises only individuals of a smaller size, the produce of an early or late spawn. Also the so-called "white-bait" is not a distinct species, but consists chiefly of the fry of the young of herrings, and is obtained "in perfection" at localities where these small fishes find an abundance of food, as in the estuary of the Thames. The important subject of herring fishing has already been treated in the article *FISHING* (see vol ix pp 251, 257, &c.)

Several excellent accounts of the herring have been published, as by Valenciennes in the 20th vol of the *Histoire naturelle des Poissons*, and more especially by M. J. M. Mitchell, *The Herring, its Natural History and Natural Exploitation*, Edin., 1864. Other treatises are—P. Neumann, *Die Heringe*, Lubek, 1651; J. S. Dault, *Essay towards a Natural History of the Herring*, Lond., 1769; L. Bolt, *Essay towards a Natural History of Herring*, Bath, 1784; *Fischerei nach Natur- und Landts Geschichte des Heringes*, Koenigsberg, 1769.

HEERNHUT, a town of Saxony, in the circle and 18 miles south east of the town of Bautzen, and situated on the Luban and Zittau Railway, is chiefly known as the principal seat of the Moravian or Bohemian Brotherhood, styled on the Continent Heerhutler, a colony of whom, fleeing from persecution in their own country, settled at Heernhut in 1722, on a site presented by Count Zinzendorf. The buildings include houses for the brethren, the sisters, and the widowed of both sexes. The town is remarkable for its regularity, cleanliness, and whiteness. Linen, paper (to varieties of which Heernhut gives its name), tobacco, and various minor articles are manufactured. The Heerhut commands a pleasant view. The population in 1875 was 1128. Dautheulorf, a village about a mile distant, has been the seat of the directorate of the community since about 1789.

HERSCHEL, CAROLINE LUCRETIA (1750–1848), sister of Sir William Herschel, the eighth child and fifth daughter of her parents, was born at Hanover on the 16th March 1750. On account of the piquedness of her mother, who did not desire her to know more than was necessary for being useful in the family, she received in youth only the first elements of education. After the death of her father in 1767 she, in order to fit herself to earn her bread, obtained permission to learn millinery and dressmaking, but continued to assist her mother in the management of the household until the autumn of 1772, when she accompanied to England her brother William, who had established himself as a teacher of music in Bath. At once she became a valuable co-operator with her brother, both in his professional duties and in the astronomical researches to which he had already begun to devote all his spare time. She was the principal singer at his oratorio concerts, and acquired such a reputation as a vocalist that she was offered an engagement for the Birmingham festival, which, however, she declined. When her brother accepted the office of astronomer-royal, she became his constant assistant in his observations, and also executed the laborious calculations which were connected with them. For these services she in 1787 received from the king a salary of £50 a year. Her chief amusement during her leisure hours was to sweep the heavens with a small Newtonian telescope planted on the lawn. Besides detecting by this means many of the small nebulae included in Sir William Herschel's catalogue,

she succeeded in discovering seven comets, in the discovery of five of which she could lay claim to priority, viz., those of 1786, 1788, 1791, 1793, and 1795. In 1797 she presented to the Royal Society a catalogue of 560 stars taken from Flamsteed's observations, and not included in the British catalogue, together with a collection of erista that should be noticed in the same volume. Though she returned to Hanover in 1822 she did not abandon her astronomical studies, and in 1828 she completed the reduction, to January 1800, of 2500 nebulae discovered by her brother. In 1835 the Astronomical Society, to mark their sense of the benefits conferred on science by such a series of laborious exertions, unanimously resolved to present her with their gold medal, and also elected her an honorary member of the society. In 1846 she received a gold medal from the king of Prussia. She retained the use of her intellectual faculties, and also preserved her interest in science, to the close of a long life. Her death took place on 28th January, 1848. *The Memoirs and Correspondence of Caroline Herschel*, by Miss John Herschel, appeared at London in 1876.

HERSCHEL, SIR FREDERICK WILLIAM (1738–1822), generally known as Sir William Herschel, one of the most illustrious of astronomers, was born at Hanover, Novem. ber 16, 1738. His father was a musician employed as harpist in the Hanoverian guards. The family had migrated from Bohemia in the early part of the 17th century, on account of religious troubles, they themselves being Protestants. Herschel's earlier education was necessarily of a very limited character, chiefly owing to the troubles in which his country at that time was involved, but, being at all times an indomitable student, he, by his own exertions, more than repaid this deficiency of his youth. He became a very skilful musician, both theoretical and practical, while his attainments as a self-taught mathematician were fully adequate to the prosecution of those branches of astronomy which, by his labours and his genius, he so eminently advanced and adorned. Whatever he did he did methodically and thoroughly, and in this methodical thoroughness lay the secret of what Arago very properly terms his astonishing scientific success.

In 1755, at the age of seventeen, he joined the band of the Hanoverian guards, and with his detachment visited England, accompanied by his father and eldest brother, in the following year he returned to his native country, but two years later, impelled by the troubles that surrounded him, he finally quitted Hanover to seek his fortunes in England. As might have been expected, the earlier part of his career in his adopted country was attended with formidable difficulties and much privation. We find him engaged in several towns in the north of England as organist and teacher of music, but these were occupations not attended with any lucrative results. In 1766 the tide of his fortunes began to flow, inasmuch as he obtained the appointment of organist to the Octagon Chapel in Bath, at that time the resort of the wealth and fashion of the city, and of its numerous distinguished visitors.

The next five or six years of his life were spent in establishing his reputation as a musician, and he thereby eventually became the leading musical authority in the place, and the director of all the chief public musical entertainments. His circumstances having thus become easier, he revisited Hanover for the purpose of bringing back with him his sister Caroline, with the view of her rendering him such services as she could in his multifarious undertakings. She arrived in Bath with her brother in August 1772, being at that time in her twenty-third year. She thus describes her brother's life soon after her arrival:—"He used to retire to bed with a basin of milk or a glass of water, with Smith's *Harmonics* and Ferguson's

Astronomy, &c, and so went to sleep buried under his favourite authors, and his first thoughts on waking were how to obtain instruments for viewing those objects himself of which he had been reading. It is not without significance that we find him thus reading Smith's *Optics*, to that study loyalty to his profession would impel him, as a reward for his thoroughness this led him to Smith's *Optics*, and thus, by a natural sequence, again led him to astronomy, for the purposes of which the chief optical instruments were devised. It was in this way that he was introduced to the writings of Ferguson and Keill, and subsequently to those of Lalande, whereby he was educating himself for an astronomer and for undying fame. In those days, telescopes were very rare, very expensive, and not very efficient, for the Dollond's had not as yet perfected even their beautiful little achromatics of 7 $\frac{1}{2}$ inches aperture. So Herschel was obliged to content himself with having a small Gregorian reflector of about 2 inches aperture, which he had seen exposed for loan in a tradesman's shop. Not satisfied with this implement, he procured a small lens of about 18 feet focal length, and set his sister to work on a pasteboard tube of that length, so as to make him a telescope. A tube of this construction naturally bent, and it was useless for all purposes but for the determined eyes of William Herschel. This material was soon displaced for tin, and thus a source of vision was obtained of Jupiter and Saturn and the moon. If then sought for a reflector of much larger dimensions from artists in London. No such instrument, however, was for sale, and the terms demanded for the construction of a reflecting telescope of 5 or 6 feet focal length he regarded as too exorbitant even for the gratification of such desires as his own. So he was driven to the only alternative that remained, he must construct a large telescope for himself. His first step in this direction was to purchase the debris of an amateur's implements for grinding and polishing small mirrors, and thus, by slow degrees, and by indomitable perseverance, he in 1774 had, as he says, the satisfaction of viewing the heavens with a Newtonian telescope of 6 feet focal length constructed by his own hands. But he was not a man to be contented with viewing the heavens as a mere stargazer, on the contrary, he had from the very first conceived the gigantic project and the hope of surveying the entire heavens, and, if possible, of ascertaining the plan of their general structure on a settled and systematic mode of procedure, if only he could but provide himself with adequate instrumental means. With this view he, his brother, and his sister toiled for many years at the grinding and polishing of hundreds of specula, always retaining the best, and rejecting the others, until the best of the numerous performances had been surpassed. This was the work of the daylight in those seasons of the year when the fashionable visitors of Bath had quitted the place, and had thus freed the family from professional duties. After 1774 every available hour of the night was devoted to the long hoped for scrutiny of the skies. In those days no machinery had been invented for the construction of telescopic mirrors, the men who had the hardihood to undertake the polishing doomed himself to walk leisurely and uniformly round an upright post for many hours, without removing his hands from the mirror, until his work was done. On these occasions Herschel received his food from the hands of his faithful sister. But his reward was nigh.

In May 1780 his first two papers containing some of the results of his astronomical observations during the last six years were communicated to the Royal Society through the influential introduction of Dr Watson. Herschel had made the acquaintance of this excellent man and skilful physician in a characteristic manner. In order to obtain a sight of the moon the astronomer had taken his telescope

into the street opposite his house, the physician happening to pass at the time, and seeing his eye removed for a moment from the instrument, requested permission to take his place. The mutual courtesies and intelligent conversation which ensued soon ripened this casual acquaintance into a solid and enduring regard.

The subject of this first memoir was the varying lustre of several of the stars, and especially that of Mira in the constellation of Cetus. It had been long known to fade in brightness from nearly that of a star of the first magnitude down to invisibility in such telescopes as then existed. Herschel had examined it, and many other variable stars, for himself, it was not, however, a simple or isolated phenomenon that engaged his attention, but, regarding the stars as so many suns, he examined similar phenomena as possibly leading him to some intelligent conception of what might be occurring in our own sun. The sun, he knew, rotated on its axis, and he knew that dark spots often exist on its photosphere, the questions that he put to himself were—Are there dark spots also on these variable stars? do the stars also rotate on their axes or do they sometimes partially eclipse by the intervention of some opaque and invisible bodies? And then he asked himself—What are these singular spots upon the sun? and have they any practical relation to us, the inhabitants of this planet? To these questions he applied his telescopes, and his thoughts, and as light from time to time dawned upon his apprehension, he communicated the results to the Royal Society in no less than six memoirs occupying very many pages in the *Philosophical Transactions*, and extending in date from 1780 to 1801. It was in the latter year that these remarkable papers culminated in the inquiry whether any relation could be traced in the recurrence of sun spots, regarded as evidences of solar activity (allied to volcanic), and the varying seasons of our planet, as exhibited by the varying price of corn? Herschel's solution of the question was scarcely final, and the question has recently cropped up again, with more than a renewal of its former interest.

In the following year (1781) he communicated to the Royal Society the first of a series of papers containing the results of his telescopic inquiries in relation to the rotation of the planets and of their several satellites. The object which he had in view was not so much to ascertain the velocities or times of their rotation, as rather to discover whether those rotations are strictly uniform. From the result he expected to gather, by analogy, the probability of an alteration in the length of our own day. These inquiries occupy the greater part of seven memoirs extending from 1781 to 1797. In the course of these telescopic observations he lighted on the curious appearance of a white spot near to each of the poles of the planet Mars. On investigating the inclination of its axis to the plane of its orbit, and finding that it closely resembled that of our earth, he concluded that its changes of climate also would resemble our own, and that these white patches were probably polar snow. Modern investigations have confirmed his conclusion. He also discovered that, as far as his observations extended, the times of the rotations of the various satellites round their axes are in analogy with our own moon, viz., equal to the times of their revolution round their primaries. Here again we observe that his discoveries arose out of the complete and systematic and comprehensive nature of the investigation in which he was engaged. Nothing with such a man is accidental.

In the same year (1781) Herschel made a discovery which, as we shall see, soon completely altered the character of his professional life. In the course of his systematic examination of the heavens with a view to the discovery of the plan of their construction, he lighted on an object which at first he supposed to be a comet, but which, by its subse-

grant motions, and appearance, turned out to be a new planet, moving outside of the orbit of Saturn. To this planet he in due time assigned the name of Georgium Sidus, but this name has by general consent been laid aside in favor of Uranus. It was discovered with a five-foot 7 foot reflector having an aperture of 6½ inches, subsequently, when he had provided himself with a much more powerful telescope, of 30 feet focal length, he discovered what he believed to be no less than six satellites. Modern observations have shown this gloomy planet of fume of these supposed attendants, but at the same time have added two others apparently not observed by Herschel. No less than seven motions on the subject were communicated by him to the Royal Society, extending from the date of the discovery in 1781 to 1816. There is a peculiarity worthy of notice in Herschel's mode of observation which led to the discovery of this planet. He had observed that the spurious diameters of stars are not much affected by increasing the magnifying power, but that the stars distant with other celestial objects, hence if anything in his telescopic field attracted his notice by peculiarity of appearance, he immediately varied the magnifying power in order to decide the nature of the object. Thus Uranus was discovered, and had a similar method been applied to Neptune, that planet would have been discovered at Cambridge some months before it was recognized at Paris.

We now come to the commencement of Herschel's most important series of observations, culminating in what ought probably to be regarded as his most capital discovery. A natural part of the task which he had set himself as the work of his astronomical life embraced the determination of the relative distances of the stars from our sun and from each other. Now, in the course of his scrutiny of the heavens, he had observed many stars in apparently very close proximity, but often greatly differing in their relative brightness. He concluded that, on the average, the brighter star would be the nearer to us, and the smaller enormously more distant. He concluded that an astronomer on the earth, in consequence of its immense orbital displacement of some 180 millions of miles every six months, would see such a pair of stars under different perspective aspects, and this variety of perspective aspect observed and measured would, he thought, lead to an approximate determination of their distance. With this view he mapped down the places and aspects of all the double stars that he met with, and communicated in 1789 and 1785 very extensive catalogues of the results. Indeed, the very last scientific memoir that he ever wrote, sent to the Royal Astronomical Society in the year 1822, at the time when he was its first president and already in the eighty-fourth year of his age, related to these investigations. In the first of these memoirs he throws out the hint that these apparently contiguous stars must, if constituted after the natural laws of our solar system, circulate round each other through the effects of gravitation, but he significantly adds that the time had not yet arrived for settling the question. Thus the philosopher abides his time in patience and confidence, and a dozen years afterwards (1793) he resumes the relative positions of many of these contiguous pairs, and we may conceive what his feelings must have been at finding the verification of his prediction. For he found that some of these stars had circulated round each other, after the manner required by the laws of gravitation. Thus Herschel had demonstrated the action of the same mechanical laws among the distant members of the stellar firmament which bind together the harmonious motions of our solar system. This sublime discovery would of itself suffice to immortalize his memory in the respectful homage of all future races of intelligent men. If only

Herschel had lived long enough to learn the approximate distances of some of these binary combinations, he would at once have been able to calculate their masses when compared with that of our own sun, and thus, knowing, as we now do, that these stars in their weights are strictly comparable with the weight of our own sun, he would have found another of his analogical conjectures realized.

In the year 1782, in consequence of his fame, Herschel was invited to Windsor by George III., and then accepted the offer made by the king to become his private astronomer, and henceforth devote himself wholly to a scientific career. The salary offered and accepted was £200 per annum, to which an addition of £50 per annum was subsequently made for the astronomical assistance of his faithful sister, Dr. Watson, to whom alone the amount of this salary was mentioned, made the natural remark, "Never before was honor purchased by a monarch so cheap a rate." In this way the great philosophical astronomer removed from Bath first to Datchet and soon afterwards permanently to Slough, within the easy access of his royal patron at Windsor.

The old pursuits at Bath were soon resumed at Slough, but with renewed vigour and without the old professional interruptions. The greater part, in fact, of the papers already referred to are dated from Datchet and Slough, for the magnificent astronomical speculations in which he was engaged, though for the most part conceived in the earlier portion of his philosophical career, required years of patient observation before they could be fully examined and realized.

It was at Slough in 1783 that he wrote his first memorable paper on the "Motion of the Solar System in Space,"—a sublime speculation, yet through his genius realized by considerations of the utmost simplicity. He returned to the same subject with fuller details in 1805. It was also after his removal to Slough that he published his first memoir containing his speculative ideas on the construction of the heavens, which from the first had been the chief aim of his toils both of mind and body. In a long series of remarkable papers, addressed as usual to the Royal Society, and extending from the year 1784 to 1813, when he was eighty years of age, he demonstrated the fact that our sun is a star situated not far from the bifurcation of the Milky Way, and that all the stars visible to us are more or less in clusters scattered throughout a comparatively thin stratum, but in the other two dimensions stretching immeasurably further into space. At one time he imagined that his powerful instruments had pierced through this stellar stratum of the Milky Way, and that he had approximately determined the form of some of its boundaries. In the last of his memoirs he had convinced himself of his error, and he admitted that to his telescopes our stratum of stars is "fathomless." Over this stratum of stars and their planetary attendants, the whole being in ceaseless motion round some common centre of gravity as the resultant point of the combined gravitation, Herschel discovered on either side a canopy of discrete nebulous masses, from the condensation of at least a part of which the whole stellar universe had been formed,—a magnificent conception, pursued with a force of genius and put to the practical test of observation with an industry almost incredible. It was the work of a single mind, carried to its termination with no assistance beyond that of a loyal sister, almost as remarkable a personage as himself.

Heretofore we have said nothing about that grand reflecting telescope, of 40 feet focal length and 4 feet aperture, which is too often regarded as the chief effort of his genius and his perseverance. The full description of this celebrated instrument will be found in the 85th volume of the *Transactions* of the Royal Society. Gigantic as it really

was, we are disposed to regard it as among the least of his great works. On the day that it was finished (August 28, 1789) Herschel saw at the first view, in a gaudier not witnessed before, the Saturnian system with all its six satellites, five of which had been discovered long before by Huygens or Cassini, while the sixth, latterly named Enceladus, he had, two years before, sighted by glimpses in his exquisite little telescope of 6½ inches aperture, but now saw in unmistakable brightness with the towering grant he had just completed. On the 17th of September he discovered a seventh, which proved to be the nearest of all the satellites of Saturn. It has since that time received the name of Mimas. It is somewhat remarkable that, notwithstanding his long and repeated scrutinies of this planet, the eighth satellite, Hyperion, and the crane ring should have escaped him.

Herschel married the widow of Mr John Pitt, a wealthy London merchant, on May 8, 1788, by whom he had an only son, John Frederick William. The prince regent conferred a Hanoverian knighthood upon him in 1816. But a far more valued and less tardy distinction was the Copley medal assigned to him by his associates in the Royal Society in 1781.

He died at Slough on August 25, 1822, in the eighty-fourth year of his age, and was buried under the tower of St Laurence Church, Upton, within a few hundred yards of the old site of the 40-foot telescope. A mural tablet on the wall of the church bears a Latin inscription from the pen of the late Dr Goodall, provost of Eton College. A collected edition of his astronomical memoirs would speak of his genius in unmistakable language, but this has not yet been published.

(O P)
HERSCHEL, SIR JOHN FREDERICK WILLIAM, BART (1792-1871), the illustrious astronomer, the only son of Sir F William Herschel, was born at Slough, Bucks, in the year 1792. His early home was a singular one, and eminently adapted to nurture into greatness any child born, as he was, with natural gifts capable of wide development. The examples about him were those of silent but ceaseless industry, busied about things which, at the first view, seemed to have no apparent connexion with the world outside the walls of his abode, but which, at a mature period of his life, he, with rare eloquence, taught his countrymen to appreciate as foremost among those influences which satisfy and exalt the noblest instincts of our nature.

His scholastic education commenced at Eton, but maternal fears or prejudices soon removed him to the house of a private tutor. Thence, at the early age of seventeen, he was sent to St John's College, Cambridge, and thence and method of the mathematical instruction he there received exercised a material influence on the whole complexion of his scientific career. In due time the young student acquired the highest academical distinction of his year, graduating as senior wrangler. It was during his undergraduatehip that he and two of his fellow students who subsequently attained to very high eminence in their respective careers of life, Dean Peacock and Mr Babbage, entered into a sort of moral compact that they would "do their best to leave the world wiser than they found it"—a compact loyally and successfully carried out by all three to the end. As a commencement of this laudable attempt we find Herschel associated with these two friends in the production of a work on the differential calculus, and on cognate branches of mathematical science, which changed the whole style and aspect of mathematical learning in England, and brought it up to the level of the Continental methods. Two or three memoirs communicated to the Royal Society on new applications of mathematical analysis at once placed him in the front rank of the cultivators of

this branch of knowledge. Of these his father had the gratification of introducing the first, but the others were presented in his own right as a fellow.

His first intention had been to study for the bar, and with this view he left the university, and placed himself under the guidance of an eminent special pleader of that day. Probably this temporary choice of a profession arose from the extraordinary success which for some time had attended the efforts of so many eminent Cambridge mathematicians in legal pursuits. Be that as it may, an early acquaintance with Dr Wollaston in London soon changed the direction of his studies. In 1820, assisted by his father, he completed a mirror of 18 inches diameter and 20 feet focal length, for a reflecting telescope. This, subsequently improved by his own hands, became the instrument which enabled him to effect the astronomical observations which, more than any other of his great works, form the basis of his fame. In 1821-23 we find him associated with Mr South in the examination of his father's double stars, by the aid of an achromatic telescope and other appliances, the like of which for excellence and power had not hitherto been collected. For this work in 1826 he received the recognition of the Astronomical Society by the award of their gold medal, the French Institute also presented him with the Lalande medal for the same contribution to astronomical science. It need also to be mentioned that in 1831 the Royal Society had presented him with the Copley medal for his mathematical contributions to their *Transactions*. From 1821 to 1827 he held the distinguished and responsible post of secretary to that society. In 1827 he was elected to the chair of the Astronomical Society, which office he also filled on two subsequent occasions. In the course of the discharge of his important offices in the last-named society he enriched its literature by his memorable presidential addresses and obituary notices of deceased fellows, which, it is not too much to say, are, by their combination of eloquence and wisdom, the chief adornments of their printed memoirs. In 1831 the honor of knighthood was conferred on him by William IV, and two years later he again received the recognition of the Royal Society by the award of one of their medals for his memoir "On the Investigation of the Orbits of Revolving Double Stars." There is a significance in this award, the father had been the original discoverer of the extension of gravitation to the remotest boundaries of the visible universe, and the son had now put the crown stone to this edifice of discovery by the invention of a graphical method whereby the eye could as it were see the two component stars of the binary system revolving before it, after the regularity of the Newtonian law.

Before the end of the year 1833, being then about forty years of age, Sir John Herschel had examined all his father's discoveries of double stars and nebulae, and had added many similar bodies to his own list, thus alone constituted a gigantic work even for the lifetime of any astronomer in that day. For it should be remembered that the astronomer was not as yet provided with those curious and valuable automatic contrivances for observing and for recording observations which at present most materially abridge the labour and increase the accuracy of astronomical work such as that in which Sir John had been engaged. And he had no assistant. Essential clocks for timing the telescope, electrical chronographs for recording the times of the phenomena observed, were at that date unknown.

His scientific life now entered another and very characteristic phase. The bias of his mind, as he subsequently was wont to declare, was towards chemistry and the phenomena of light, rather than towards astronomy. Indeed, very shortly after taking his academical degree at Cambridge, he proposed himself as a candidate for the vacant

chair of chemistry in that university, but, as he said with some humour, the result of the election was that of the votes he had a glorious minority of one. In fact Herschel had become an astronomer from a sense of duty, just as his father had become one by fascination and fixed resolve, hence it was by filial loyalty to his father's memory that he was now impelled to undertake the completion of that work which at Slough had been so grandly commenced. William Herschel had explored the northern heavens, John Herschel determined to explore the heavens of the south, as well as to explore the north. "I resolved," he said, "to attempt the completion of a survey of the whole surface of the heavens, and for this purpose to transport into the other hemisphere the same instrument which had been employed in this, so as to give a unity to the results of both portions of the survey, and to render them comparable with each other." In accordance with this resolution, he and his family embarked for the Cape on the 13th November 1833, they arrived in Table Bay on the 16th January 1834, and, proceeding, he says, "were pushed forward with such effect that on the 22d of February I was enabled to gratify my curiosity by a view of κ Cygnus, the nebulae of γ Argus, and some other remarkable objects in the 30-foot reflector, and on the night of the 4th of March to commence a regular course of sweeping."

To give an adequate description of the vast mass of labour completed during the next four busy years of his life at Fiddlemouth would require the transcription of a considerable portion of the *Cape Observations*, a volume not only of great scientific and valuable interest to astronomers, but by its scientific work in execution, although it might perhaps be regarded by a judicious selection from Sir William's *Almanac*, now scattered in some thirty volumes of the *Philosophical Transactions*, as published at the sole expense of the late Duke of Northumberland, but not till 1817, since we find the author's return to England, for the very name is now required to have it. The object of the observations, as well as the nature of work of reducing, arranging, and preparing them for the press, have been occupied by myself. There are 261 pages of catalogues of stars in nebulae and clusters of stars. There are then careful and often too minute descriptions of the appearance of the great nebula in Orion, and of the region surrounding the remarkable star of Argos. The labour and the thought bestowed upon some of these objects are almost incalculable, several months were well spent upon a minute spot in the heavens containing little star, but which an ordinary spangle, held at a distance of an inch's length, would eclipse. These catalogues and charts being completed, he proceeds to discuss their significance, which in the view of some philosophers is a dubious matter. He confirms his father's hypothesis that these wonderful masses of glowing vapours are not irregularly scattered, and without apparent law, hither and thither in the vast void, but are distributed in a series of canopy, these canopies at the pole of that vast system of stars in which our solar system holds its position,—based in it, as he supposed, at a depth not greater than that of the average distance from us of an α Centauri magnitude star. There follows his account of the relative positions and magnitudes of the southern double stars. And he applies to one of them, γ Virginis, that beautiful graphical method invented by himself, whereby he determines the orbit of the two components round each other, and he had the satisfaction of witnessing with his own eyes the fulfilment of a prediction he had made some years before, viz., that the two stars would, in the course of their orbital movements, appear to lose up into a single star, in a period being 15 years 10 months. The double stars and their steady revolutions and lustreous colours discussed, in the next chapter he proceeds to describe the observations which he had made on their varying and relative brightness. It has been already stated how his father's manner of his scientific work by similar observations on the varying magnitudes of many stars, and how his remarks published years afterwards in the question whether the variation of the lustre of our sun, by the prediction of absence of sun spots, affected our harvests and the price of corn. The son carries his speculations backwards to a still more philosophical depth. The variation from time to time, he remarks, in the lustre of our sun, to the extent of half a magnitude, is a real cause for those strange alterations of a semi Arctic and semi tropical climate which geological researches have disclosed as having occurred in various regions of our globe.

Herschel returned to his English home in the spring of 1838. As was natural and honourable to all concerned, he was welcomed with an enthusiastic greeting. By the queen

at her coronation he was created a baronet, and, what to him was better than all such rewards, other men caught the contagion of his example, and laboured in fields similar to his own, with an adequate portion of his success. In particular Mr Lassell transported a telescope as large as the celebrated Herschelian telescope to Malta, where with excellent results he "minded the heavens" for the space of four years. He was rewarded there, and at his own English residence near Lavepool, by the discovery of new satellites of Saturn and of Uranus, constituting what Sir John Herschel, animated by a paternal sympathy, well called an epoch in astronomy. Mr De La Rue also, at Islington and at Crayford, followed zealously and successfully in the wake of the same infectious enthusiasm.

Herschel was a highly accomplished chemist. His discovery of the solvent power of hyposulphate of soda on the otherwise insoluble salts of silver, in 1819, exercised a most important influence on the practical applications of photography twenty years afterwards, and in 1839, the natal era of that valuable art, he, independently of Mr Fox Talbot, had discovered the means of taking and multiplying photographic pictures, and early in the spring of that year exhibited more than twenty photographic pictures to the Royal Society, including one of the old 40 foot telescope. He was the first person to introduce the new well-known terms *positive* and *negative* in photographic images, and to deposit upon glass a sensitized film for the reception of the picture. He also paved the way for Professor Stokes's important discovery of the change which luminous waves may suffer in their period of oscillation, by his addition of the lavender rays to the spectrum, and by his announcement of "epidic dispersion," as exhibited by sulphate of quinine. Several other important and successful researches of his, connected with the undulatory theory of light, are scattered through the pages of his treatise on "Light" published in the *Encyclopædia Metropolitana*.

To the other varied accomplishments of his gifted mind we must add the graces of a deep poetic feeling. Perhaps no man can become a truly great mathematician or great philosopher, if unendowed with the versatile powers of the imagination. John Herschel possessed this endowment to a large extent, and he had reserved for himself as a solace and enjoyment in old age the translation of the *Iliad* into verse. He had at an earlier period of life translated in a similar manner Schiller's *Wallenstein*. But the main work of his declining years was the collection of all his father's catalogues, combined with his own observations and those of other astronomers of nebulae and double stars, each into a single volume. He lived to complete the former, and to present it to the Royal Society, who have published it in a separate form in the *Philosophical Transactions*. The latter work he had not fully completed at his death, but he bequeathed as much of it as was finished to the Astronomical Society. That society has printed a portion of it, which serves as an index to the observations of various astronomers on double stars up to the year 1866.

A complete list of his various contributions to learned societies will be found in the Royal Society's great catalogue, and from them may be gathered most of the records of his busy scientific life. Sir John Herschel met with an amount of public recognition which was unusual in the time of his illustrious father. Naturally he was a member of almost every important learned society in both hemispheres. For five years he held the office of master of the mint, the same appointment which, more than a century before, had been occupied by Sir Isaac Newton, his friends also offered to propose him as president of the Royal Society and again as a member of parliament for the university of Cambridge, but neither office was within the scope of his own desires.

In private life Sir John Herschel was a firm and most ardent friend, he had no jealousy, he awarded all scientific favours, he gladly accorded a helping hand to those who consulted him in scientific difficulties, he never discouraged, and still less disparaged, men younger than or inferior to himself, he was pleased when his own work was appreciated, but that was never an object of his solicitude—it was said of him by a discriminating critic, and without extravagance, that "his was a life full of the serenity of the sage and the docile innocence of a child."

He died at Collingwood, his residence near Hawkhurst in Kent, May 11, 1871, in the seventy-ninth year of his age, and his remains are interred in Westminster Abbey close to the grave of Sir Isaac Newton.

Sir John Herschel, independently of the labours connected with his *Cape Observations*, was the author of several books, one of which at least, *On the Study of Natural Philosophy* (1830), possesses an interest which no future advances of the subjects on which he wrote can obliterate from the attention of thoughtful men in any age. In 1840 came the *Outlines of Astronomy*, of which it is enough to say that, notwithstanding the obvious disadvantage arising from the practice of abridging text-books which relate to progressive sciences, there is no more instructive volume extant on the subject of which it treats. His articles, "Meteorology," "Physical Geography," and "Telescope," contributed to the 8th edition of the *Encyclopædia Britannica*, and also were published separately. There is also another very valuable little book, which originated from a happy peculiarity of Sir John Herschel's dignified simplicity and timidity of mind. When he was at the Cape he more than once assisted in the attempts there made to diffuse a love of knowledge among men not noted in letters. To cut his addresses he, with a kindly and far-seeing wisdom, told his audience that the advance of a nation's intelligence or a nation's fame did not depend upon a few superficial philosophers toying in their lonely studies, and gathering great reputations for their leaning on their elbows; but that a nation's progress rather lay in the diffusion of their knowledge among the masses of the population. Acting practically on this principle, he wrote a series of French pamphlets, in *Good Words* and elsewhere, a series of papers on important points of natural philosophy, which have since been collected in a volume called *Popular Lectures on Scientific Subjects*. None but a deep thinking philosopher could have written this book, none but a calm thinking mystic of his subjects could have made it what it is, ontologically intelligible. Another volume of his, not so widely known to the public as any of the above works, is his *Collected Addresses*, in which he is seen in his freest and most instructive mood, talking, as it were, at liberty among sympathizing associates, in his own fields, and enamoured of their beauties. (C. P.)

HERSENT, Louis (1777-1860), French painter, was one of David's most distinguished pupils, and became one of the most noted painters of the Restoration. He was born at Paris on 10th March 1777, and obtained the Prix de Rome in 1797, in the Salon of 1802 appeared his *Metamorphosis of Narcissus*, and he continued to exhibit with rare interruptions up to 1837. His most considerable works under the empire were Achilles pining from Baisin, and Atala dying in the arms of Chactas (both engraved in Landon's *Annales du Musée*), an Incident of the life of Fénélon, painted in 1810, found a place at Malmaison, and Passage of the Bridge at Landshut, which belongs to the same date, is now at Versailles. Hersent's typical works, however, belong to the period of the Restoration, Louis XVI relieving the Afflicted (Versailles) and Daphnis and Chloe (engraved by Langier and by Galle) were both in the Salon of 1817, at that of 1819 the Abduction of Gustavus Vasa brought to Hersent a medal of honour, but the picture, purchased by the Duke of Orleans, was destroyed at the Palais Royal in 1848. His most successful work, Henriquel-Dupont is now its sole record. Rich, produced in 1823, became the property of Louis XVIII, who from the moment that Hersent rallied to the Restoration zealously patronized him, made him officer of the Legion of honour, and pressed his claims at the Institute, where he replaced Van Spaendonck. He continued in favour under Charles X, for whom was executed Monks of Mount St Gotthard, exhibited in 1824. In 1831 Hersent made his

last appearance at the Salon with portraits of Louis Philippe, Marie Amélie, and the duke of Montpensier, that of the king, though good, is not equal to the portrait of Spontini (Berlin), which is probably Hersent's *chef-d'œuvre*. After this date Hersent ceased to exhibit at the yearly salons. Although in 1846 he sent an excellent likeness of Delphine Gay and one or two other works to the rooms of the Société d'Artistes, he could not be tempted from his usual reserve even by the international contest of 1855. Five years later, on 2d October 1860, he died. His work shows every artistic merit which can be attained by steadily directed intelligence and labour, his skillful arrangement, delicacy of line, and certainty in execution are points which have excited the admiration even of those who find him wanting in feeling, in interest, and in sense of colour. Louis XVI relieving the Afflicted, the treatment of which indicates the approach of the romantic movement, is less theatrical than Daphnis and Chloe, which combines, in the true spirit of the Restoration, drawing-room graces with a pseudo-classic style, but both show the same dryness and hardness of manner which Hersent had acquired under the influence of the first empire, and from which he never was able to free himself.

HEILSFELD, a town of Prussia, capital of a circle in the government district of Cassel, province of Hesse-Nassau, is pleasantly situated at the confluence of the Fulda and Hanne with the Fulda, on the railway from Frankfurt to Biele, 10 miles NNE of Fulda. The greater part of its old fortifications remain, but the ramparts and ditches have been laid out as promenades. The principal buildings are the ancient town house, the parish church, completed in 1320, in the Gothic style, with a fine tower and a large bell, the ruins of the collegiate church in the Byzantine style, erected in the beginning of the 12th century on the site of the cathedral, but burnt down by the French during the Seven Years' War, and outside the town the ancient monastery with its surrounding grounds. Among the public institutions are a gymnasium, a higher town school, an orphanage, and a district infirmary. The town has important manufactures of cloth and leather, as well as dye works, woolen mills, and soap boiling works. The population in 1875 was 6929.

Heilsfeld owes its origin to a Benedictine abbey which, founded by Illudis, archbishop of Mainz, about 760, was richly endowed by Charlemagne, and became in the 12th century an ecclesiastical principality. In 1870 the town came under the jurisdiction of Prussia, and in 1825 it gave in its former allegiance to it. The abbey was secularized in 1618, but Heilsfeld remained the capital of a prince bishopric.

HERSTAL, or in its older form *Hirastalt*, a market-town of Belgium, on the left bank of the Meuse, 3 or 4 miles north-east of Liège, and skirting the road which leads from that city to Maastricht. Its population, which in 1876 numbered 11,136, is mainly supported by its coal mines and non-industries. Herstal probably derives its name from being a "Hirastelle" or permanent camp of the Franks. It is well known as the birthplace and family seat of Pippin, the major-domo of the Austrasian kingdom, some few traces of whose estate are still pointed out above the town. And though it cannot maintain its claim to be the birthplace also of Charlemagne, it was undoubtedly a frequent place of residence for this great of the Carolingians, and in 870 it gave its name to the treaty by which Charles the Bald and Lewis the German decided the partition of Lotharinga. The lordship of Herstal passed to the house of Nassau in 1411, and in 1702, on the death of William III of England, its possession was disputed between the house of Orange and the king of Prussia. The decision of the courts was given in 1714 in favour of Prussia, but the new possessors, finding the feelings of the people of Herstal against them, sold the lordship to Liège.

for 140,000 thalers. Another Harz, distinguished as the Saxo, was the place where Charlemagne had his winter quarters in the year 797. It is now the village of Herstelle on the Weser, in the government of Minden.

HERTFORD, COUNTY OF, HERTFORDSHIRE, OR HARTS, an inland county in the south east of England, is situated between 51° 36' and 52° 5' N lat and 0° 13' E and 0° 45' W long. It is bounded on the N by Cambridgeshire, N W by Bedfordshire, E by Essex, S by Middlesex, and S W by Buckinghamshire. The area comprises 391,141 acres or 611 square miles.

The aspect of the county is pleasant and picturesque, its surface being broken by gentle undulations which in some parts form a quick succession of hills and valleys. The highest summit is Kensworth Hill on the border of Bedfordshire, about 910 feet above sea-level. Fine oak and other trees are grown in the hedges, and from being planted obliquely they form high walls of living timber shading narrow winding lanes. The arable and pasture lands of the fanns are intermingled with the parks and ornamental woods of the country seats which are scattered thickly throughout the county. These features, varied by its winding rivers, impart to it a peculiar beauty, while in luxuriance it is not surpassed by any county in England.

The principal rivers are the Lea, which, rising some miles beyond Luton in Bedfordshire and entering Hertfordshire at Nivellum, flows south east to Hatfield and then east by north to Hatfield and Ware, whence it bends southward, and passing along the eastern boundary of the county falls into the Thames a little below London, having received in its course the Marn, the Beane, the Rib, and the Stort, which all flow southward in the north-eastern part of the county, the Stort for some distance forming the boundary between it and Essex, the Colne, which, flowing through the south western part of the county, falls into the Thames at Buntingford, having received in its course the Ver, the Bullen, and the Gule, the Ivel, which, rising in the north-west of the county, soon passes into Bedfordshire. The New River, one of the water supplies for London, made by Sir Hugh Myddelton (1607-13), has its source in some springs near Ware, and runs parallel for many miles with the Lea. The Grand Junction Canal from London to Birmingham traverses the south-west corner of the county, passing by Watford and Buskhamstead. There are mineral springs in the parishes of Chipping Barnet, Nottaw, and Watton.

Geologically the county consists of Cretaceous and Tertiary rocks, the greater part being Lower, Middle, and Upper Chalk, which in the south-eastern part of the county is covered by Tertiary deposits belonging to the London basin. Over a large part of the eastern side of the county there are superficial deposits of glacial origin, and on the western side there are traces of the Lower Tertiary beds having formerly extended over a much wider area, outliers of the beds being of not infrequent occurrence, and the drift deposits on the chalk hills being largely composed of their debris. The vales traversed by the rivers and streams exhibit in the bottoms a rich sandy loam, the sloping sides are covered by loams of inferior quality, and the flat surface of the high ground is generally formed of a loam of reddish hue tending towards common clay, with which it is often confounded.

The climate is mild, dry, and remarkably salubrious. On this account the London physicians were accustomed to recommend the county for persons in weak health, and it was so much coveted by the noble and wealthy as a place of residence, that it was a common saying—"He who buys a home in Hertfordshire pays two years' purchase for the air."

According to the agricultural returns for 1870, the total area of arable land was 239,187 acres, of which 116,956 acres were under corn crops, 39,443 under green crops, 38,416 under rotation crops, 97,548 permanent pasture, and 13,111 fallow. The area under woods was 29,714 acres. It will thus be seen that the main produce of Hertfordshire is corn. The principal crop is wheat, which in 1870 occupied 99,363 acres. The varieties mostly grown are white, and they are not surpassed by those of any county in England. Wheat is the staple of the river Lea, and is a fine specimen of the quality of the wheat grown in this district. Of barley, which is largely made use of in the county for malting purposes, there were 45,129 acres in 1870, and of oats only 25,779. Little or no rice is grown, and of rice and lucerne together there was in 1870 a little over 11,000 acres. Of green crops, turnips and Swedes occupied in 1870 an area of 21,778 acres, while potatoes in only 2,767. Vetches are largely grown for the London market, extending to 5,912 acres in 1870. The greater part of the permanent grass is made use of for hay. There are some very rich pastures on the banks of the river Stort, extending from Hatfield to Hemel Hempstead on the borders of the river Lea, and also near Rickmansworth, where they are watered by the river Colne. The percentage of cultivated area in 1870 was 86.7 instead of 85.1 in 1870, of arable under corn crops 37.3 instead of 38.5, under green crops 10.1 instead of 11.6, under rotation crops 9.8 instead of 10.2, and of permanent pasture 21.9 instead of 23.0. The most common system of rotation is the five-course—turnips or fallow, barley, clover, wheat, oats. In the south-west part of the county large quantities of cherries and apples are grown for the London market. On the best soils no use is made of London manure, but the following are the most common, and more than one crop can sometimes be obtained in a year.

Generally speaking, the quantity of stock kept is small. Not much attention is paid to the breeding of cattle, but among cows the Suffolk variety is the most common. The number of cattle in 1870 was only 31,754, or an average of 9.8 to every 100 acres under cultivation, the average for England being 11.0, and for the United Kingdom 11.0. Of these the number of cows in 1870 was 11,803. The number of horses in 1870 was 15,022, or an average of 4.1 to every 100 acres, the average for England being 4.5 and for the United Kingdom 4.1. The horses used for agricultural purposes are chiefly Suffolk ponies. The number of sheep in 1870 was 171,133, or an average of 60.4 to every 100 acres under cultivation, the average for England being 75.3, and for the United Kingdom 68.0. The principal kinds are the Southdown and Wiltshire, and a cross between Cotswolds and Leicesters. There were in 1870 30,401, or an average of 8.9 to every 100 acres under cultivation, the average for England being 7.2, and that for the United Kingdom 6.7. In Hertfordshire the number of resident proprietors is very large, which circumstance, as well as the proximity to London, has doubtless greatly aided the development of agricultural enterprise. The average extent of the farms is about 200 acres, and the modern improvements are everywhere adopted.

According to the return of owners of land for 1872-73, the soil was divided among 12,387 proprietors, holding land to the gross annual rental of which was £1,383,709. Of the owners 77 per cent held less than one acre, and the total number of acres for the county was £2, 17s. 8d. per acre. There were only eight families who held upwards of 4000 acres, viz., Marquis of Salisbury, Hatfield, 18,369; Abbot Smith, Watton, 10,212; Earl Cowper, Panshanger, 10,122; Earl Spencer, Buskhamstead, 8,216; St. Albans, 8,225; Earl Brownlow, Ashridge Park, 8,551; Lord Deane, The Hoe, Welwyn, 7100; Charles C. Hale, Kings Walden, 5658; and Earl of Essex, Chesham Park, Watford, 6167. W. R. Baker, Buntingford, comes next with 5121 acres.

The staple trade of the county is in corn and malt, most of which is sent to the metropolis. There are numerous flour-mills, as well as breweries, tanneries, the works, and coach factories, but the manufacture of iron is unknown in the county. Hertfordshire is so much intersected by railways that no place in any part of the county is more than 6 miles distant from a station. On the eastern border there is the Great Eastern, which runs to Hatfield and Buntingford. The middle of the county is traversed by the Great Northern, with branches from Hatfield to Hatfield, Luton, Dunstable, and St. Albans, and from Hitchin to Royston, and thence to Cambridge. The Midland passes through Watton, and has branches to the Great Northern and London and North Western. The London and North-Western traverses the south western corner.

The county comprises 8 hundreds, and the municipal boroughs of Hatfield and St. Albans. The municipal towns are the municipal and parliamentary borough of Hatfield (municipal borough, 7160), the city of St. Albans (8298), Hitchin (7690), Watford (7491), Bishop Stortford (6260), Hemel Hempstead (5540), Ware (4017), Buntingford (4088), Tring (4048), and Buskhamstead (3728). For parliamentary representation the county is an undivided constituency, and returns three members, while one member is returned for the borough of Hatfield. Hertfordshire is in the south-eastern circuit. There were formerly two courts of quarter sessions, one for the

county and one for the liberty of St Albans, which liberty had also a separate constitution. At the present, both the county and the liberty are now amalgamated, though prisoners are tried both at Hertford and St Albans. The jail for the county is at the latter city. The county is divided into eight wards, several divisions, and for voting purposes into two divisions. Those of Hertford and the liberty of St Albans. The boroughs of Hertford and St Albans have commissions of the peace. Accidentally the county is in the diocese of St Albans, rural deanery, however, as places, as well as parts of other parishes extending into adjoining counties. The total population in 1872 was 102,226, of whom 88,234 were males and 98,982 females. The population in 1881 was 174,290. Since the first census in 1801 it has increased by 91,683, or 97 per cent.

History and Antiquities.—Previous to the Roman invasion the Celtic inhabitants of Hertfordshire, as of the other parts of South Britain, had been subdued by the Belgæ. In 610 A. D. Constantine, the chief of the Cossai, led an army to oppose Cædwa, but he was defeated, and his capital Verulam, now the present town of St Albans, taken. At Verulam and Baldrehamsted, the seats of ancient British princes may yet be seen, and it has been concluded that British stations existed at Royston, Basingham, and various other places in the county. Numerous British coins have been found at Verulam. The principal British roads or trackways crossed the county. Watling Street passed through its south-west corner, in a north-west direction by St Albans (to Dunstable), Marnes Street entered the south-east corner at Little Hockley, whence it was called by Gough's Oak, and ran due north by Ware, being thence named the main course as the present road by Dunsford to Royston, Icknield Street, from Dunstable to Royston, crossed the north-west corner. There are numerous barrows at Royston, and along the fringe of chalk hills at the south-east corner, the Hertfordshire was the scene of an important part of the struggle carried on against the Romans by Caractacus about A. D. 50, and during the rebellion of Boadicea the Romans were defeated on the road from Verulam to Colchester, and Verulam itself was taken and destroyed by the Britons. The same was included within the Roman province of Flavia. Among the Roman stations within its limits was the capital, Verulamium, which the Romans rebuilt and fortified, *Verulamium*, not far from Dunstable, of which ruins are still to be seen near Basingham, where there are remains of a wall with fosse, and probably others at Royston and Dunsford. Watling Street and Marnes Street entered the county at the latter place, and the roads traversed the county in various directions. Roman antiquities have been found at Verulam, Basingham, Royston, Wilbury Hill (where there are remains of an ancient camp), Chesham, Elmal Homestead, and Bishop Stortford. After the conquest of England by the Anglo Saxons, Hertfordshire was included partly in Mercia and partly in Essex. It was the scene of frequent contests between the Saxons and the Danes. In 809 the Danes, having surrounded their vessels in the Lea near the town of Ware, laid siege to Hertford, whereupon Alfred the Great, by dividing the stream into three channels, stranded their vessels and compelled them to retreat to the Severn. After the battle of Brunan in 1065, William the Conqueror, in order to force the earls to bury their homes from London to their castles, crossed the Thames at Watlington and marched into Hertfordshire, where at Baldrehamsted a banquet was made by the abbot of St Albans, at which he caused by cutting down the trees at a meeting of nobles held at the town he took an oath to rule according to the ancient laws and customs of the country. The subsequent events of historic importance connected with the county are the capture of St Albans, 17th February 1461, in which the French dauphin, December 6, 1216, the battle between the royalists and the armies of the White Rose at St Albans, May 22, 1455, in which Henry VI was wounded and taken prisoner, a second battle near St Albans, 17th February 1461, in which the Duke of Warwick was defeated by Queen Margaret, the defeat near Banet of the end of Warwick by Edward IV, 14th April 1471, and the arrest by the Duke of the high sheriff of the county as he was proceeding to St Albans for the purpose of receiving by order of Charles I. that all the Parliamentary commanders were rebels and traitors.

Among the objects of subsequent interest may be mentioned the cave of Royston, rediscovered in 1722, doubtless at one time used as a shelter, and containing rude carvings of the crucifixion and other sacred subjects, Watlitham cove, in the Pounted style of architecture, (restored in 1836), erected by the Duke of Devonshire, the tomb of Eleanor, Queen of Edward I, on its way to Worcester for interment, and the Great Bed of Ware referred to in Shakespeare's *Twelfth Night*, for many years shown to visitors at the Crown Inn of that town, and in 1864 put up to auction at the residence of the Marquis of Epsom for 100 guineas and bought by the Earl of Devonport. The remains of the priory of St Albans abbey, founded about 793 in honour of the first Christian martyr of Great Britain, the remains of Sopwell, Beaulieu, and other religious houses, founded in 1140, and the remains of the priory of Ware, dedicated to St Francis, and originally a cell to the monastery of St Ebrulf at Utica in Normandy,

and the remains of the priory at Hitchin built by Edward II for the White Camlets. Among the most interesting churches may be mentioned those of Abbots Langley and Hemel Hempstead, both of Late Norman architecture, the latter a fine instance of the building supposed to have been erected by the knights Templars in the reign of Stephen, Royston, formerly connected with the priory of the canons regular, Hitchin, built in the 15th century on the site of an older station, with a fine porch in the Perpendicular style and an entrance by Rixbury, Hitchin, dating from the 13th century, Baldrehamsted, which in the Perpendicular style, with a tower of the 16th century. The ruins of secular buildings of importance in the county are the Elmal Homestead, castle, Hitchin castle, Hitchin palace, the slight traces at Bishop Stortford, and the earthworks at Verulam. Of the numerous mansions of which only a few can be mentioned—the Rye House, erected in the reign of Henry VI, situated at Dunstable, one of the municipal agents in the plot to assassinate Charles I, a Moor Park, Rickmansworth, at one time the property of St Albans abbey, granted by Henry VII to John de Vere, earl of Oxford, for some time in the possession of Cardinal Wolsey and subsequently of the duke of Monmouth, who built the present mansion, which, however, after it was sold by the duchess of Monmouth to Sir Miles, was covered with Portland stone, and received various other additions at a cost of £10,000, Knowlton, the seat of the Leytons, originally a Norman fortress, rebuilt in the time of Elizabeth in the Tudor style, and restored in the present century, Hildesheim, the mansion which was granted to the abbot of St Albans in 1534 by King Edward, and with the palace was sold over to Henry VIII, from whom it remained a royal residence until the time of James I, who exchanged it for the palace of Whitehall with Sir Robert Cecil, afterwards earl of Salisbury, by whom the present mansion in the Elizabethan style was erected, known as Hildesheim House, now the principal seat of the Cowpers, a splendid mansion in the Gothic style erected at the beginning of the present century, Chesham House, the seat of the Copleys, supposed to date from the time of the old British tribe, the name of the house in which was formerly held by the abbot of St Albans, built in the beginning of the present century from designs by Wyatt, containing the remains of Watlitham Castle, Chesham House, formerly the seat of the Bricons, and the residence of the present chancellor, but rebuilt by the Grimstons. Among the numerous places connected with the county were Nicholas Dinkley, near Royston, 17th century, Elmal Homestead, near Marnes, William Cowper, Charles Lamb, and Lord Lytton.

The old history of Hertfordshire by Rev. Salmon, and chronicle, has been revised by the schoolmaster of Chesham, and the present edition is the latest compilation now in course of publication by John Edwin Thomas.

HERTFORD, a town of England, capital of the above county, is situated in a sheltered valley on the river Lich, and on the Great Northern and Great Eastern Railways, 26 miles north of London by rail. It is somewhat irregularly built, but is neat, clean, and well paved. The principal buildings are the steeple house or town hall, situated on the site of the former castle, finished in 1771, the corn exchange, erected in 1856, the church, the county gaol, recently restored, a cruciform structure of the 11th century, with a square tower surmounted by a spire, the new church of St Andrews, occupying the site of the old one, the brick edifice which occupies the site of the ancient castle, and includes some portions of the old building, and the infirmary. The county jail has lately been sold under the provisions of the new Prisoners Act. There are a large number of educational institutions, including the preparatory school for Christ's Hospital, London, Hule's grammar school for boys, the Cowper Testimonial school for boys, the Abel Smith Memorial school for girls, and the Green Coat school for boys and girls of poor parents, who have no recovered alms. The town depends for its prosperity chiefly on agriculture. The trade is principally in wheat and wool, and a large quantity of malt is made for the London brewers. There are also breweries, iron foundries, and flour and oil mills. The population of the municipal borough in 1871 was 7109, and of the parliamentary borough 7894. The area of the municipal borough is 861 acres, and of the parliamentary borough 1123 acres.

The name Hertford is identified by Bede with *Heretford*, meaning red ford, but more probably it is a corruption of *Hertrind*, meaning any ford, and indeed it is so called in this way by Devon antiquaries, and in some historic charter. In 978 a council was convened at Hertford by Theodoric, Archbishop of Canterbury, at which two

Sixteen kings attended. The castle was erected about 905 by Harald the Elder, who at the same time rebuilt the town, which had in all probability been devastated by the Danes. Its custody and the government of the town were given by William the Conqueror to Peter de Valognes. Subsequently it was surrendered to the crown. In the reign of John it was captured by the rebel barons headed by the duke of Flanders. By Edward III. the castle was made the occasional prison of John II. King of France and David King of Scotland. Hardest was recorded as a borough in Domescday. It received its first charter from Queen Mary in 1557, and this was renewed and modified by Elizabeth, and confirmed and enlarged by James I. and Charles II. The borough sent two members to parliament from the reign of Edward I. to the 50th of Edward III., when the privilege was suspended until the reign of James I. Since the Reform Act of 1907 it has returned only one member.

HERTZ, HENRIK (1798–1870), Danish poet, was born of Jewish parents in Copenhagen, August 25, 1798. At that date it was unusual for Jews to enjoy a professional education, but young Hertz showed such marked literary bias that in 1817 he was sent to the university. His father having died in his infancy, and the family property having been destroyed in the bombardment of 1807, the boy was brought up by his relative, M. L. Nathanson, for many years editor of the principal Danish newspaper. Young Hertz was destined for the law, and passed his juridical examination in 1826. But his taste was all for poetic literature, and in 1827 he came forward as a dramatic author by the production of two plays, *Herz and his Family* and *Love and Policy*, the latter enjoyed considerable success on the stage. In 1828 followed the comedy of *Fløjtefangeren*, which occupied itself with the humorous of moving house on quarter-day. In 1830 he brought out what was a complete novelty in Danish literature, a drama in rhymed verse, *Amor's Strokes of Genius*. In the same year Hertz published anonymously *Gjenganger-bjergene*, or Letters from a Ghost, which he pretended were written by Baggese, who had died in 1826, and which were full of satirical humour and fine critical insight. The success of this book was overwhelming; Copenhagen talked of nothing else for a whole season, but Hertz preserved his anonymity, and the secret was not known until many years later. In 1832 he published a didactic poem, *Nature's Law*, and *Four Poetical Epistles*. *A Day on the Island of At* was his next comedy, followed in 1835 by *The Only Fault*. Hertz passed through Germany and Switzerland into Italy in 1835; he spent the winter there, and returned the following autumn through France to Denmark. In 1836 his comedy of *The Savings Bank* enjoyed a great success. But it was not till 1837 that he developed his most important talent by writing the romantic drama of *Queen Dagmar's House*, a beautiful and original piece, which still holds the stage. His historical tragedy *Valdemar Atterdag* was not so well received in 1839, but in 1845 he achieved an immense success with his lyrical drama *King René's Daughter*, which has been translated into almost every European language, and successfully acted all over the civilized world. To this succeeded the tragedy of *Ninon* in 1848, the romantic comedy of *Tonietta* in 1849, *A Stormy Night* in 1853, *The Youngest* in 1854. His lyrical poems appeared in successive collections, dated 1832, 1840, and 1844. From 1858 to 1859 he edited a very interesting literary journal entitled *Weekly Leaves*. He died in 1870. Hertz is one of the first of Danish lyrical poets. His poems are full of colour and passion, his versification has more witchcraft in it than any other poet's of his age, and his style is grace itself. He has all the sensuous fire of Keats without his proclivity to the antique. As a romantic dramatist he is scarcely less original. He has been quoted to the Danish theatre, in *Queen Dagmar's House* and *King René's Daughter*, two pieces which have survived the vicissitudes of forty years, and which are as popular as ever. He is a troubadour by instinct, he has little or

nothing of Scandinavian local colouring, and succeeds best when he is describing the scenery or the emotions of the glowing south.

HERTZNER, ALEXANDER (1812–1870), was born at Moscow in 1812, a very short time before the occupation of that city by the French. His father, Ivan Yakovlev, after a personal interview with Napoleon, was allowed to leave, when the invaders arrived, as the bearer of a letter from the French to the Russian emperor. His family attended him to the Russian lines. Then the mother of the infant Alexander (a young German Protestant of Jewish extraction from Stuttgart, according to A. von Wunbach), only seventeen years old, and quite unable to speak Russian, was forced to seek shelter for some time in a peasant's hut. A year later the family returned to Moscow, where Hertzner passed his youth,—remaining there, after completing his studies at the university, till 1834, when he was arrested and tried on a charge of having assisted, with some other youths, at a festival during which verses by Sokolovsky, of a nature uncomplimentary to the emperor, were sung. The special commission appointed to try the youthful culprits found him guilty, and in 1835 he was banished to Viatka. There he remained till the visit to that city of the hereditary grand duke (afterwards Alexander II.), accompanied by the poet Joukovsky, led to his being allowed to quit Viatka for Vladimir, where he was appointed editor of the official gazette of that city. In 1840 he obtained a post in the ministry of the interior at St. Petersburg, but in consequence of having spoken too frankly about a death due to a police officer's violence, he was sent to Novgorod, where he led an official life, with the title of "state councillor," till 1842. In 1846 his father died, leaving him by his will a very large property. Early in 1847 he left Russia, never to return. From Italy, on hearing of the revolution of 1848, he hastened to Paris, whence he afterwards went to Switzerland. In 1852 he quitted Geneva for London, where he settled for some years. In 1864 he returned to Geneva, and after some time went to Paris, where he died, January 21, 1870.

His literary career began in 1842 with the publication of an essay, in Russian, on *Utilitarianism as Science*, under the pseudonym of "Iskander," the Turkish form of his Christian name,—convicts, even when pardoned, not being allowed in those days to publish under their own names. His second work, also in Russian, was his *Letters on the Study of Nature* (1845–6). In 1847 appeared his novel *Kto Vinovat?* (Whose Fault?), and about the same time were published in Russian periodicals the stories which were afterwards collected and printed in London in 1854, under the title of *Pravennye Russkani* (Interrupted Tales). In 1850 two works appeared, translated from the Russian manuscripts, *Vom anden en Ufer* (From another Shore) and *Letit de France et d'Italie*. In French appeared also his essay *Du Développement des idées révolutionnaires en Russie*, and his memoirs, which, after being printed in Russian, were translated under the title of *Le Monde à l'usage de la Révolution* (3 vols. 1860–62), and were in part translated into English as *My Exile to Siberia* (2 vols., 1855). From a literary point of view his most important work is *Kto Vinovat?* a story describing how the domestic happiness of a young tutor, who marries the unacknowledged daughter of a Russian sensualist of the old type, dull, ignorant, and genial, is troubled by a Russian sensualist of the new school, intelligent, accomplished, and callous, without there being any possibility of saying who is most to be blamed for the tragic termination. But it was as a political writer that Hertzner gained the vast reputation which he at one time enjoyed. Having founded in London his "Free Russian Press," of the fortunes of which, during ten years, he gave an interesting account in a book published (in Rus-

man) in 1863, he issued from it a great number of Russian works, all levelled against the system of government prevailing in Russia. Some of these were essays, such as his *Baptized Property*, an attack on serfdom; others were practical publications, the *Polynaya Zvezda* (or Polar Star), the *Kokhol* (or Bell), and the *Golosa iz Rossii* (or Voice from Russia). The *Kokhol* soon obtained an immense circulation, and exercised an extraordinary influence. For three years, it is true, the founders of the "Free Press" went on printing, "not only without selling a single copy, but scarcely being able to get a single copy introduced into Russia," so that when at last a bookseller bought ten shillings' worth of *Baptized Property*, the half sovereign was set as a lib by the surprised editors in a special place of honour. But the death of the emperor in 1855 produced an entire change. Hertzka's writings, and the journals he edited, were smuggled wholesale into Russia, and then were reprinted throughout that country, as well as all over Europe. Their influence became overwhelming. Evil deeds long hidden, evil doers who had long prospered, were suddenly dragged into light and disgrace. His bold and vigorous language aptly expressed the thoughts which had long been secretly stirring Russian minds, and were now beginning to find a timid utterance at home. For some years his influence in Russia was a living force, the circulation of his writings was a vocation seriously pursued. Stories tell how on one occasion a merchant, who had bought several copies of a sermon at Nyin Norogorod, found that they contained forbidden print instead of Bibles, and at another time a supposititious copy of the *Kokhol* was printed for the emperor's special use, in which a telling attack upon a leading statesman, which had appeared in the genuine number, was omitted. At length the sweeping changes introduced by Alexander II greatly diminished the need for and appreciation of Hertzka's assistance in the work of reform. The freedom he had demanded for the serfs was granted, the law courts he had so long denounced were reformed, and by jury was established, liberty was to a great extent conceded to the press. It became clear that Hertzka's occupation was gone. When the Polish insurrection of 1863 broke out, and he pleaded the insurgents' cause, his reputation in Russia received its death-blow. From that time it was only with the revolutionary party that he was in full accord, and it is by that section of Russian Liberals alone that his opinions are now considered of authority. For the great reforms, however, which followed the Crimean War, Russia is much indebted to the outspoken utterances of Alexander Hertzka, and will be so in all probability for the constitutional changes which are likely to follow the repressive measures of 1879.

In 1873 a collection of his works in French was commenced in Paris. A volume of posthumous works, in Russian, was published at Geneva in 1870. His *Memories* supply the principal information about his life, a sketch of which appears also in A. von Wierzbick's *Zeitgenossen*, pt. 7, Vienna, 1871. See also the *Revue des Deux Mondes* for July 15 and Sept. 1, 1854. His *Parables* has been translated into German under the title of *Wörter und Scheld* in Wolfsohn's *Russische Novellenscheiter*, vol. iii. The title of *My Days in Siberia* is misleading; he was never in that country. (W. R. B.)

HERULI, ERULI, or ERULI, a nomadic and warlike German tribe who inhabited the northern shores of the Black Sea, but afterwards divided into various sections and wandered into different parts of Europe. They made their first appearance in history in the 3d century, as taking part with the Goths in their incursions against the eastern provinces of the Roman empire. In the 4th century they acknowledged the overlordship of the Gothic king Ermanaric, but when Athila, king of the Huns, made his descent upon Gaul, they joined his standard. After the overthrow of the Huns, in which they suffered considerably, they established an organized and distinct confederacy on the banks

of the Danube, and under the leadership of Odoocei, assisted in 476 in the overthrow of the Western empire. Under their king Rulf they in the beginning of the 6th century attempted the subjugation of the Longobards, but were defeated and dispersed, some of them proceeding to Scandinavia, and others being allowed by the emperor Anastasius to settle on the south bank of the Danube. In the time of Justinian some of them embraced Christianity. A large portion of them afterwards joined the Gepids, in their wars against the Eastern empire, but others who remained afforded Justinian important assistance in his wars against the Vandals and East Goths, so that they frequently fought against one another. About the end of the 6th century they became submerged and lost in other nations, and disappeared from historical records. The Heruli were bold, hairy, and extremely pugnacious. For a considerable period they retained intact their strong individuality, and presented a firm resistance to the influences of surrounding civilizations. They put to death without mercy the sick and the aged, and also said even to have offered human sacrifices.

HERVEY, JAMES (1711-1788), a popular religious writer of the 18th century, was born at Haddington, near Northampton, on February 20, 1714, and was educated at the grammar school of Northampton, where in 1731 he passed to Lincoln College, Oxford. At the university he came under the influence of John Wesley and others of that school, and for some time manifested an inclination towards their theology, ultimately, however, while retaining his regard for the men and his sympathy with their religious aims, he adopted a thoroughly Calvinistic creed, and resolved to retain connexion with the Established Church. Having taken holy orders in 1737, he became curate to his father in the family living of Weston Favell and Collingtree, to which he himself succeeded in 1752. There, under the disadvantage of very weak health, he laboured with great diligence in the discharge of his pastoral duties, and also wrote numerous religious works, which, though of but slight literary or theological value, rapidly became highly popular, and in many English and Scottish houses, especially of the humbler class, took a place in the same shelf with the *Pilgrim's Progress* and the *Whole Duty of Man*. His earliest work, *Meditations and Contemplations*, containing "Meditations among the Tombs," "Reflections on a Flower Garden," and a "Descent on Creation" (1746), and "Contemplation on the Night and Morning Heavens" (1747), said to have been modelled on Boyle's *Christian's Reflections on various Subjects*, within fourteen years passed through as many editions. *Thou art my Son, or a Series of Letters upon the most important and interesting Subjects*, which appeared in 1755, and was equally well received, called forth some adverse criticism even from Calvinists, on account of tendencies, which were considered to lead to antinomianism, and was strongly objected to by Wesley in his *Preservative against unscriptural notions in Religion*. Besides carrying into England the theological disputes to which Fisher's *Marrow of Modern Divinity* had given rise in Scotland, it also led to what is known as the Sandemanian controversy as to the nature of saving faith. Hervey died on December 25, 1788. A "new and complete" edition of his *Works*, with a memoir, appeared in 1797. See also *Collection of the Letters of James Hervey, to which is prefixed an account of his Life and Death* (1760).

HERVEY, JOHN ILIARVEY, LOAN (1696-1743), the "Narrative," "Sports," and "Lord Fanny" of Pope's satire, a nobleman of political and social distinction in the reign of George II, was son of John first earl of Bristol, and was born on October 13, 1696. Educated and trained for public life at Westminster and Clare Hall, Cambridge, he became a

favourite at the court of the prince and princess (afterwards George II. and Queen Caroline), to which Pope, Gay, Arbuthnot, Chesterfield, and other wits resorted, and which was celebrated for the beauty and accomplishments of its ladies, such as Miss Bellenden (afterwards duchess of Argyll), Miss Howe, Miss Lepell, and Miss Howard, whose names will live for ever in the poetry of Pope, Gay, and Swift, and in the lively memoirs and correspondence of that brilliant circle Harvey was married to Miss Lepell in 1730.

Having entered the House of Commons as member for Bury (1735), he in 1730 received the appointment of vice-chamberlain to the king, in 1733 Sir Robert Walpole called him up to the House of Lords, where he proved a frequent and effective speaker, and in 1740 he succeeded Lord Godolphin as lord privy seal, which office he held until the Walpole administration was driven from power in 1743. Notwithstanding miserable health he continued to take an active part in politics until his death, which occurred on August 8, 1743. He was survived by four sons, three of whom became successively earls of Bristol. Distinguished by any commanding talents or solid principle, a sceptic in religion and a prodigal in morals, Lord Harvey was yet far above the intellectual rank assigned him by his merciless satirist, Pope. He wrote and spoke vigorously on public questions, was studious and laborious, a fair scholar, and a writer of pleasing occasional verse. The origin of the hostility which led to the allusion in the *Dunciad* (iv. 104) in 1728, and afterwards to the attacks in the *Poetical* and *Epilogues to the States*, remains obscure. "It would be now idle," as Mr Croker remarks, "to seek for a cause of quarrel which the parties were, a hundred years ago, unable or unwilling to explain, but may it not be sufficiently accounted for by the jealousies almost inevitable between persons of such similar and therefore discordant tastes and tempers, living together in a circle of titillate, scandal, and piquanteur?" Political differences had probably something to do with it. Lord Harvey and Lady Mary Wortley Montague (who shared with him the poet's enmity) living at the accession of George II. adhered to Walpole, while Pope and his brother wits were chiefly associated with the opposition. Lord Harvey left behind him *Memoirs of the Reign of George the Second, from his Accession to the Death of Queen Caroline*, which were not published until 1848, when they appeared in two volumes, edited, with a biographical notice, by Mr Croker. His work throws much light on the interior of the court—its courtesies, duties, and immorality, but it is as degrading to the author as it is to the English monarchy, for Lord Harvey appears rather in the light of a court parasite and malignant gossip than in that of a fair historian or an English gentleman.

HERZEGOVINA, an Illyrian province, ethnographically belonging to the Serbo-Croatian nationality, under the titular dominion of the Turkish sultan, but since 1878 administered by Austria-Hungary. The Turks included it in the vilayet of Bosnia. It is bounded N. and E. by Bosnia, S. by Montenegro, and W. by Dalmatia, only touching the Adriatic by the narrow enclaves of Klek and Sutoutina. The province extends about 117 miles in a south-east direction between 17° 10' and 20° 16' E. long. By the treaty of Berlin the Herzegovinian districts of Niksch and Dornitor have been placed under the government of the prince of Montenegro.

Population—The Austrians have not yet (1879) had time to complete trustworthy statistics as to the population and resources of the province, and those published in the days of Turkish administration must be received with great reserve. The best statistical accounts of Herzegovina are those collected for the Austrian Government by the staff-

officers Majors Roskiewicz and Thoemmel, and their discrepancy is the best proof of the difficulties which have hitherto prevented an exact calculation.

According to Roskiewicz the population of Herzegovina amounted in 1868 to 230,000 souls. Thoemmel (in 1867) gives it as 207,970, of whom 101,348 were Pravoslavs or adherents of the Orthodox Greek Church, 56,000 Mahometans, 49,217 Roman Catholics, 1340 Gipsies, and 65 Jews. Dr Blas (late Prussian consul-general at Sarajevo) fixes the Herzegovinian population in 1873 approximately at 230,000, viz., 130,000 of the Orthodox Greek Church, 55,000 Mussulmans, 42,000 Roman Catholics, 2000 Gipsies, and 600 Jews. Klatsch, however, the most recent Slavonic authority on the province (1878), reduces the total population to 185,421. During the troubles that ensued on the insurrection of 1875, about two thirds of the Christian population fled beyond the Dalmatian and Montenegrin borders, and the fearful mortality among these refugees has largely diminished the Herzegovinian population during the last three years.

With the exception of the Gipsies, the Jews, and a small sprinkling of Osmanli officials, the whole population is Slavonic, the Mahometans being for the most part renegade descendants of the feudal nobility that had formed itself here before the Turkish conquest. Much of the old Slavonic customs and family life still holds among the Herzegovinian Mussulmans, and here as in Bosnia polygamy is unknown. The Herzegovinians are tall, broad, and darker, and of greater personal bravery than the Bosnians, they are brachycephalic. In frame as well as character they approach very nearly to the Montenegrin type, and in the mountain districts they are divided, like the Montenegrins and Albanians, into clans or nahies, whose loyalty is reserved for their own wavrodes or military chiefs. Their temperament is pre-eminently poetic, in so much that the recent insurrection has already given rise to many epic lays, which are recited to the sound of the guzle or Serbian lute by the national minstrels. The Serbo-Croatian language is spoken in its purest form in Herzegovina, and the Neretva valley has been called the Serbian Val d'Aino. The Orthodox Greek population is chiefly settled in the district east of the Neretva, to the west of that river the population is mostly Roman Catholic, and the Mahometans inhabit the larger towns. According to the *Schematismus* of the Franciscan P. Bakula, the population of the capital Mostar amounted in 1873 to 29,116, of whom 20,806 were Mahometans, 5008 Greeks, and 2281 Roman Catholics. Of the other towns, Igoubski has, according to Klatsch, a population of about 8000 souls, Stoklets 5500, Fochia 10,000, Niksch (now under Montenegro) 4000, and Trebinje 3000.

Natural Features—Herzegovina, which has been described as the Turkish Switzerland, is divided into a variety of mountain plateaus by the parallel ranges of the Dinara Alps, and the whole country is bisected by the river Neretva, which cleaves its way through the mountains from the Bosnian frontier towards the Adriatic. The valley of the Neretva and its tributaries forms the main artery of the province. There is situated the capital Mostar, and a fine highroad, the only avenue of communication between Sarajevo (Bosnia) and the Adriatic, follows the river bank from the Dalmatian frontier to the Bosnian. The "polyes" or mountain plateaus are the most characteristic feature of the country. The smaller towns and villages group themselves on their level and comparatively fertile surface, and the districts or cantons thus formed are walled round by a natural rampart of white limestone mountains. These "polyes" may be described as oases in what is otherwise a desert expanse of mountains. The surface of some, as

notably the great Mostarsko Blato, is marshy, and in spring forms a lake, others are watered by streams which disappear in swallow-holes of the rock, and make their way by underground channels, either to the sea or the Neretva. The most conspicuous example of these is the Trebinjtska, which disappears in two swallow-holes in Popovogorje, and after making its way by a subterranean passage through a range of mountains, wells up in the mighty source of Omblina near Rogusa, and hurries in undiminished volume to the Adriatic. The climate of Herzegovina is cold in winter and oppressively hot (maximum 100° Fahr in shade) in summer. The sunococe is a prevalent wind, as well as the bora, the fearful north-north-easter of Illyria, which, sweeping down the lateral valleys of the Dinare Alps, overwhelms everything in its path. The snow-fall is slight, and, except on a few of the loftier peaks, the snow soon melts. In the valleys, as that of the Neretva, the flora approaches that of Dalmatia and Southern Italy, and olives, mulberries, figs, melons, pomgranates, grapes, rice, and maize flourish. The Dinare Alps, which stretch across the province from N W to S E, are as a rule bolder and loftier than those of Bosnia. To the west of the Neretva, indeed, then flanks are in places covered with a forest growth of beech and pine, but north-east of that river they present for the most part a scene of lunar desolation. They are of the Tertiary formation common to the Mediterranean geological zone, but their limestone has a more dolomitic character than that of the Bosnian ranges. The group of mountains in the north-west bend of the Neretva, the Krabac, Lapeta, and Porim Planina, attain altitudes varying from 4000 to 5000 feet, the dolomitic peaks of Orobie, Samotice, and Velika Cap rise over 6000, Orjen on the Dalmatian Montenegro frontier 6300, and Mount Dobrovi, in the tract of Herzegovina now ceded to Montenegro, reaches a height of 8500 feet. The river Neretva is navigable for small steamers as far as Metkovich, the Dalmatian frontier station, and for *trabucos* as far as Chaplina beyond Gabella, but the narrow and rocky bed of the stream beyond this point makes it doubtful whether the navigation can ever be extended as far as Mostar.

Produce and Industries.—In mineral wealth Herzegovina cannot compete with Bosnia. Lignite exists in considerable abundance in the Neretva valley near Mostar, at Konjica, and at Stolac. Mineral springs occur near Ljubuska, asphalt towards Metkovich and Drazovo on the Dalmatian frontier. Rice is cultivated in the Trebinjtsa valley and about Ljubuska. Mulberries are cultivated in the Neretva valley for silk-worms, which were introduced here by the famous viceroy Ali Pasha, but the culture is at present small. The wine of Konjica and Mostar resembles Dalmatian, and might be excellent, and the Trebinje tobacco is celebrated. Previous to the insurrection the chief wealth of the inhabitants consisted in cattle. Roskiewicz estimates the numbers as 100,000 horned cattle, 1,200,000 sheep and goats, and 100,000 swine, but there has been a terrible decrease during the three years of anarchy. Before the insurrection the annual value of the exports of the province, consisting principally of sheep's wool, hides, wax, wine, and tobacco, amounted to about 18,170,000 *pastras* (£163,530). The imports, principally cloth and woollen goods, were estimated at 17,500,000 *pastras* (£157,500).

History.—The old Serbian prince of Chaim of Zachlumie was incorporated in the banat of Bosnia by the son Stephen in 1396. Afterwards exchanged for Primorje with the king of Hungary, it was possessed by the son Stephen Tvrtko, afterwards first king of Bosnia, who granted it as a fief to his distinguished general Vukobran. Vukobran's grandson, known as Stephen Cosmoza from his birthplace Cosma, took advantage of the weakness of King Tvrtko III. of Bosnia to transfer the immediate suzerainty of his county to the emperor Frederick IV. who in 1440 created him duke, or, as his Slavonic subject, borrowing the German word, expressed it, *Zinseps*, of St. Sava. Thus and the further title of keeper of St. Sava's

sepulchre he derived from the tomb of the patron saint of Serbia in his monastery of Milasevo. From this time the Slav population of Illyria begins to know the dominions of Cosmoza as the "Herzegovina" or duchy, a general term which embraced besides the county of Chaim, the two counties of Slavonia and Croatia, and Primorje, also governed by the "Herzogs." The original *Herze* govern thus extended from the sea coast of Dalmatia to the confines of Russia. The duke was prevailed on at the parliament of Koprivica to recognize the suzerainty of the Bosnian king, but had his residence at Mostar, which he greatly enlarged, and which his sons assumed the capital of Herzegovina. The showed policy of Stephen Cosmoza, which offered an asylum for the Bogomils on the coast, was abandoned from that homes by the election of a prince, public king, was greatly instrumental in leading off for a while from the duchy the blow that overwhelmed Bosnia. The duke married with Bogomil in help to defend Herzegovina with some success, and though in 1486 the country was overrun and rendered tributary by the sultan's hordes, it was not till 1483, twenty years after the final conquest and extinction of the Bosnian kingdom, that the Turkish Begins succeeded in disposing of Stephen Cosmoza's son and successor Duke Vladislav. The whole country was now incorporated in the Sandjakate of Bosnia. At different times the Venetians succeeded in recovering for Christendom parts of Herzegovina, and by the peace of Covento in 1699 and that of Passarowitz in 1718 Primorje on the Herzegovinian coast land, Crstomono, and Jitovno were finally merged in Venetian Dalmatia, and thus thus descended to the Austrians. The only remaining parts of Herzegovina were, of course, the remote enclaves of Kikinda, Srebrenica, and Ugljevik. The history of Herzegovina under the Turks is to a great extent a blank, the vicissitudes of Herzegovina were interrupted by their gross misdeeds, and the Bosnian sultan's defiant attitude adopted by the duke of St. Sava to his Bosnian successor. Feudalism under a Mohammedan crown continued to survive here. The saphs, begs, or lords, were really independent lords who had acquired to themselves the rights of the medieval castles, their banners, their judicial title deeds and prerogatives of nobility. They exacted feudal service from their vassals and taxations on the medieval system, and their domains were held by the Malakotian nobles, Ali, aga of Stolac, did such good service for Sultan Mohammed in his struggle with the Bosnian magnates that he was made viceroy of Herzegovina, which was held for a while from feudal anarchy on the Bosnian government. The sultan's government did not by any means remove the grievance of the 15th population of Herzegovina. The sultan had now to satisfy the extinction of imperial tax-farms and excise as well as the demands of the feudal lords. The begs and agas continued to exact their feudal labour and a third of the produce, the central Government at least a tithe which at the date of the outbreak had become an eighth. These kinds of cattle tax, the tax for exemption from military service levied on every infant in arms, forced labour on the roads, forced loan of horses, a heavy excise on grapes and tobacco, and a variety of lesser taxes combined to burden the Christian peasants, but what was more galling than the amount, was the manner in which these various taxes were exacted,—the imposition of the tax-farms and excises, and the brutal licence of the saphs who were quartered on recalcitrant villages. Mohammed the conqueror of the empire, and the sultan, were the cause of the oppression of his subjects, and the punishment of his subjects was the cause of the public bankruptcy of Turkey, but the last act on the part of the Turk. On July 1, 1878, the villagers of Nevesin, which gives its name to a mountain plain east of Mostar, were the first to revolt against the tax-farmers, and goaded to madness by the outrage inflicted on them by the saphs and bashi-bazucs, rose against their oppressors. The insurrection rapidly spread through Herzegovina and thence to Bosnia. The Herzegovinian army, which was led by Pavlovich, Soces, Ljubanich, and others held out for a year against all the forces that Turkey could dispatch against them, and in two struggles in the gorge of Munatovic the brave Turks held out for 8000 men. In July 1878 the Austrians entered the struggle, the Russo-Turkish war followed, and led to the treaty of Berlin the government of Bosnia and Herzegovina was ceded to Austria-Hungary, while Nikola and the counts about Mount Dobrovi were detached from Herzegovina and annexed to Montenegro. On July 31, 1878, the Austrians tore down the *Herze* governan frontier, and the news reached the Malakotian faithful to a desperate effort. On August 31 the Malakotians of Mostar, and its vicinity, excepting Srebrenica, and the whole of the province, joined the Turkish Government, rose en masse, murdered the Turkish governor and officials, and proclaimed a ulama head of a provisional government. The Austrians, however, pressed forward, and crushing some inefficient efforts of the Malakotians, entered Mostar on August 31. By the 29th of September the reduction of Herzegovina was completed by the capture of the hillfort of Klobink. Since the completion of the occupation, the government of the province has been under the military governor at Srebrenica, controlled by the foreign office at Vienna. The sultan still remains sovereign *de jure*, but

proceeds, from the spontaneous generation of Erebos and Night from Chaos, to detail a cosmogonic epos at first corresponding with the Mosaic. The first rule of creation, Uranus, is disabled and dethroned by Cronos, and Cronus in turn by his sixth son by Rhea, Zeus, but the churning of Titans and Cyclopes, of Neleids and Oceanids, divine rivers and water nymphs, defies even the briefest enumeration. The poet has interwoven several episodes of rare merit, such as the contest of Zeus and the Olympian gods with the Titans, or the description of the prison house in which the vanquished Titans are confined, with the Giants for keepers and Day and Night for janitors (735 seq.) Notable also is the version of the legend of Pandora given in the *Theogony* as compared with that in the *Works and Days*. The *Theogony* omits the part played in the earlier poem by Epimetheus in accepting Pandora at Jove's hands in spite of the counsel of Prometheus, as well as the mention of the casket of evils from which in the *Works and Days* Pandora lifts the lid with such woeful results.

The only other approach to a poem of Hesiod is the so called *Shield of Hercules*, a piece of patchwork with which interpolators have done their worst. The opening verses are attributed by a nameless grammarian to the fourth book of *Eclogæ*. The theme of the piece is the expedition of Hercules and Iolaus against the robber Cyclops, but the main object apparently is to describe the shield of Hercules (141—317). C. O. Müller seems this description worthy of a place beside Homer's shield of Achilles in *Il. vii.*, and recognizes in it the genuine spirit of the Hesiodic school. Titles and fragments of other lost poems of Hesiod have come down to us, such as, the *Mænimæ of Chiron*, genealogie, as the *Ægymnus*, and myths, as the *Messenger of Cypris* and the *Descent of Theseus to Hades*.

A strong characteristic of Hesiod's style is his sententious and proverbial philosophy (as in *Works and Days*, 24—5, 40, 218, 345, 571). These are naturally less in this in the *Theogony*, yet there too not a few sentiments take the form of the saw or adage. With the poet's history, apart from the evidence of his poems, we have little acquaintance. There is reason to suppose that in later life he removed from Assos to Orchomenus, where, according to Pausanias, were his sepulchre and epitaph. Tradition has assigned a tragical ending to a life seemingly placid and unemotional, but the story that he met a violent death near the Locrian Ciconæ in the territory of Naupactus, by reason of an intrigue with a sister of his host, or a guilely knowledge of such intrigues, is probably valueless, except as evidence of the hero-worship of Hesiod in Locris and Boeotia of Fœdel, *Die Sage von Tode Hesiods*, Leipzig, 1879). The poet will be remembered as the first of didactic poets, the accredited systematizer of Greek mythology, and the rough but not unpoetical sketcher of the lines on which Virgil wrought out his exquisitely finished *Georgics*.

Among the older editions of the Hesiodic poems may be mentioned those published at Venice in 1495 and 1537, and those of Housæus (Leipz. 1822), Schœnius (Leipz. 1850), Gœrner (Amst. 1791), Robinson (Oxon. 1737), and others. Of more modern date, Fœdel (Leipz. 1861), Lehrs (Leipz. 1840, new ed. 1865), Schœnius (Bail. 1869), Koehly and Kinkel (Leipz. 1870), Flach (Bail. 1871). The *Works and Days* has been edited separately by Spälin (Leipz. 1819), Vollhart (Kiel, 1844), Lennep (Amst. 1847), and the *Theogony* by F. A. Wolf (Halle, 1788), Lennep (Amst. 1848), Schœnius (Bail. 1869), and Flach (Bail. 1873). The fragments were collected by Malasschaff (Leipz. 1840). Many disputed questions associated with the name of Hesiod have given rise to a vast critical and polemical literature. In regard to the language of the poems the student may consult W. Gœrner, "Krit. Beiträge zur Lehre vom Dialecten in Cyprien, Stalien, u. d. d. H. Flach, *Die dialektische Dialecten des Hesiodos* (Bail. 1876), and Rader, *Die Dialecten des Hesiodos* (Leipz. 1876). This composition and system

of the *Theogony* have been investigated by Kock (Bail. u. 1812), Gœrner (Kiel 1856), Wölcker (Elberst. 1865), Lehrs (Munich, 1867), Schœnius (Bail. 1868), Flach (Leipz. 1871), Fœdel (Leipz. 1873), and special studies on the *Works and Days*, such as contributed by Thesleff (Bail. 1819), Hake (Götting. 1838), Stütz (Leipz. 1869), Bekk. (Münster, 1872), and Gœrner (Leipz. 1874). Works of more general criticism are Gœrner, and Henmann, *Beiträge zur Homer und Hesiod* (Halle 1817), Thesleff, *Über die Geschichte der Hesiod'schen Dichtung* (Halle 1817), Mithoff, "Studies in Greek Literature," in *Æschylus*, u. The MSS are discussed by Flach, *Die beiden Hesiod'schen Epiken* (Leipz. 1877), Kinkel, *Die Hesiod'schen Epiken* (Leipz. 1877), Gœrner (Halle 1869), Wölcker, "Über die Hesiod'sche Dichtung," in *St. ung. u. d. H. Flach*, *Die Hesiod'schen Epiken* (Leipz. 1877), Gœrner (Halle 1869), Wölcker (Leipz. 1869), Flach (Leipz. 1871), Kinkel (Leipz. 1877), and Flach (Leipz. 1873). German translations by J. F. Voss (Halle 1806) and U. v. d. L. (Bail. 1867), French translations by Leconte de Lisle (Paris 1869) and P. P. (Paris 1873-8), and Italian by Chiodi (Cosenza, 1867) and Mazzoni (Milan, 1878).

HESPERIDES, maidens whose number is variously given as three, four, or seven, who gnawed the golden apples which Earth gave Iliad at her marriage to Zeus. They live far away in the west at the borders of Ocean, in other words at that point of heaven where the sun sets. Hence the sun (according to Mæneius) sails in the golden bowl that Hesperus made from the abode of the Hesperides to the land where he rises again. According to other accounts they dwell among the Hyperboreans, who live in quiescence and calm, i. e., the sun never sets among the souls of them that have died on earth. The golden apples grow on a tree which is guarded by an ever-watchful dragon. The sun is often in German and Lithuanian legends described as the apple that hangs on the tree of the nightly heaven, like the fleece of the sunman that was sacrificed and skinned, and the dragon, the envious power, keeps the light back from men till some bountiful power takes it from him. Hesperos is the hero who brings back the golden apples to mankind again. Laila or Leuco, his first applies to the Nymphs, who help him to learn where the garden is. Arrived there he slays the dragon and carries the apples to Argos, and finally, like Perseus, he gives them to Athens. The Hesperides are, like the Furies, beautiful singers, *Ἀργυρόεσσαι*. They are said to be the daughters of Atlas, or, according to other accounts, they are the children of Erebos and Night, or Phœbus and Leto, and are thus sisters of the Græes, who also receive into their care the setting sun. Hesperides are introduced into the Argonautic legend, but it is doubtful if this is really antique, or only a poetic embellishment of the wanderings of the Argonauts.

HIESS. Amongst numerous German artists of this name, the following particularly deserve attention:

HENRIK HANS HIESS—Von Hies, after he received a patent of personal nobility—was born at Dux, in 1798, and brought up to the profession of art by his father, the engraver Karl Ernst Christoph Hies. Karl Hies had already acquired a name when in 1806 the Elector of Bavaria, having been raised to a king by Napoleon, transferred the Duxeldorf academy and gallery to Munich. Karl Hies accompanied the academy to its new home, and there continued the education of his children. In time Munich Hies became sufficiently master of his art to attract the attention of King Maximilian. He was sent with a stipend to Rome, where a copy which he made of Raphael's *Parasceus*, and the study of great examples of monumental design, probably caused him to become a painter of ecclesiastical subjects on a large scale. In 1828 he was made professor of painting and director of all the art collections in Munich. He decorated the *Altehrliche*, the *Glyptothek*, and the *Allerheiligenkirche* at Munich with frescoes; and his cartoons were selected for glass windows in the cathedrals of Cologne and Ratisbon. Then came the great cycle of frescoes in the basilica of St. Boniface at Munich,

and the monumental picture of the Virgin and Child enthroned between the four doctors, and reserving the homage of the four patrons of the Munich churches (now in the Pinakothek). His last work, the Lord's Supper, was found unfinished in his atelier after his death in 1863. Before testing his strength as a composer Heinrich Hess tried genre, an example of which is the Pilgrims catering Rome, now in the Munich Gallery. He also executed portraits, and twice had sittings from Thoma's Walden (Pinakothek and Schack collections). But his fame will rest on the frescos representing scenes from the Old and New Testament, in the Allerheiligenkapelle, and the episodes from the life of St Boniface and other German apostles in the basilica of Munich. Here he holds rank second to none but Overbeck in monumental painting, being always true to a truth though mindful of the traditions of Christian art, earnest in its simple in feeling, yet lifelike and powerful in expression. Through him and his pupils the sentiment of religious art has been preserved and extended in the Munich school, and will not easily die out.

PETER HESS—afterwards Von Hess—was born at Dusseldorf in 1793, and accompanied his younger brother Heinrich Maria to Munich in 1806. Being of an age to receive vivid impressions, he felt the stirring impulses of the time, and became a painter of skirmishes and battles. In 1813-17 he was with the staff of General Weyrother, who commanded the Bavarian in the military operations which led to the abdication of Napoleon, and thus he gained novel experiences of war and a taste for extensive travel. In the course of years he successively visited Austria, Switzerland, and Italy. On Prince Otto's election to the Greek throne King Louis sent Peter Hess to Athens to gather materials for pictures of the war of liberation. The sketches which he then made were placed, forty in number, in the Pinakothek, after being copied in wax on a large scale (and little to the edification of German feeling) by Nitzsch, in the northern academies of the Hofgarten at Munich. King Otto's entrance into Naxos was the subject of a huge and crowded canvas now in the Pinakothek, which Hess executed in person. From these, and from battlepieces on a scale of great size in the Royal Palace, as well as from military episodes executed for the emperors Nicholas, and the battle of Waterloo now in the Munich Gallery, we gather that Hess was a clever painter of horses. His conception of subject was lifelike, and his drawing invariably correct, but his style is not so congenial to modern taste as that of the painters of touch. He finished almost too carefully with thin medium and pointed tools, and on that account he lacked to a certain extent the boldness of Horace Vernet, to whom he was not unaptly compared. He died suddenly, full of honour, at Munich, in April 1871. Several of his genre pictures, horse hunts, and brilliant scenes may be found in the gallery of Munich.

KARL HESS, the third son of Karl Christoph Hess, born at Dusseldorf in 1801, was also taught by his father, who hoped that he would obtain distinction as an engraver. Karl, however, after engraving one plate after Adrian Ostade, turned to painting under the guidance of Wagenbauer of Munich, and then studied under his elder brother Peter. But historical composition proved to be as contrary to his taste as engraving, and he gave himself exclusively at last to illustrations of peasant life in the hill country of Bavaria. He became clever alike in representing the people, the animals, and the landscape of the Alps, and with constant means of reference to nature in the neighbourhood of Reichenhall, where he at last resided, he never produced anything that was not impressed with the true stamp of a kindly realism. Some of his pictures in the museum of Munich will serve as examples of his manner. He died at Reichenhall on the 16th of November 1874.

HESSE, or HESSIA (in German *Hessen*), an old county of Germany situated on both banks of the Rhine and Main, north and south of Frankfurt, has had different boundaries at different times. Its greatest length was about 95 miles, while its breadth has varied considerably. Several detached portions of territory were also included in Hesse.

The earliest recorded inhabitants of the district were the Chatti, whose chief settlement Mattium, probably near Gudensberg, was destroyed by Germanicus in 15 A.D. The Chatti, merged in the Franks, migrated westward, and their place in Hesse was taken by the Saxons. Among these, when conquered by the German kings, several "graus" or earldoms were founded, some of whose possessors after the death of Charlemagne rose to great power. Two families—those of Wertheim and of Cisso, count of Gudensberg—became latterly the most important. In 1130 the heiress of the Cissos married the landgrave of Thuringia, who thus became the overlord of Hesse. In 1247 the Thuringian male line became extinct, and Hesse, along with the other possessions of the landgrave, was involved in a prolonged war of succession. In 1263 Sophia, duchess of Brabant and niece of the last landgrave, received by treaty the landgraveate of Hesse, as it was from that time called, and two years later resigned it in favour of her son, Henry the Child, the ancestor of the present house of Hesse. Till the death of Philip the Magnanimous in 1567, Hesse continued to be regarded as one state, though sometimes shared by two rulers, but at that date Philip's four sons divided the landgraveate into Hesse-Cassel, Hesse-Marburg, Hesse-Rheinfels, and Hesse-Darmstadt. Of these the second and third lapsed by inheritance in 1583 and 1604 to the others, which became the chief lines. The small landgraveate of Hesse-Homburg was formed in 1596 of part of Hesse-Darmstadt. Hesse-Darmstadt, since the annexation of the other two to Prussia in 1806, has been the only independent part of Hesse left, and generally receives the common name.

Hesse-Nassau is a province of Prussia, formed in 1866 from parts of Hesse-Cassel and the dukedom of Nassau. Hesse-Philippsthal was a collateral line of the house of Hesse-Cassel, founded in 1830, and extinct in 1820. Hesse-Darfeld, Hesse-Dutzbach, Hesse-Rothenburg, Hesse-Ramstein, and Hesse-Wanfried were collateral lines of little importance.

For further information see Tuetzen, *Aufschlüssliche Geschichte des Hessens*, 1777-80; Wernke, *Hessische Landeskunde*, 1788 and 1800; Fries, *Über den Gluthausen und Hamschen*; Schenk and the others, *Geschichte des Chattiischen Stammes*, 1668; Hoffmeister, *Historisch-geographisches Handbuch über alle Ländchen des Regenten Hauses Hessen*, 1874; Bonnell, *Geschichte von Hessen*, 1820-58, 10 vols.; Heppner, *Hessische Kirchen- und Schulgeschichte*, 1876.

HESSE-CASSEL, in German KURHESSEN, &c., Electoral Hesse, now forming the government district of Cassel in the Prussian province of Nassau, was till 1866 a landgraveate and electorate of Germany, consisting of several detached masses of territory, to the NE of Frankfurt-on-the-Main. It contained a superficial area of 3699 square miles, and its population in 1864 was 745,063.

The line of Hesse-Cassel was founded by William IV., surnamed the Wise, eldest son of Philip the Magnanimous. On his father's death in 1467 he received one half of Hesse, with Cassel as his capital, and thus formed the landgraveate of Hesse-Cassel. Additions were made to it by inheritance from his brother's possessions, while, as compensation for losses sustained in the Thirty Years' War, a large part of the county of Schaumburg and other territory was acquired towards the middle of the 17th century. Charles I., who succeeded the throne in 1707, was the first ruler who adopted the system of hiring his soldiers out to foreign powers as mercenaries, as a means of improving the national finances. Frederick I., the next landgrave, had become by marriage king of Sweden, and on his death was succeeded in the landgraveate by his brother, William VIII., who fought as an ally of England in the Seven Years' War. From his grandson Frederick II., who had become a Roman Catholic, 23,000 Hessian troops were hired by

England for about 23,191,000, to assist in the war against the North American colonies. The sign of the next Landgrave, William IV., was an important epoch in the history of Hesse-Cassel. Ascending the throne in 1786, he took part in the war against France a few years later, but in 1798 was obliged to give up the treaty of Basel. For the loss in 1801 of his possessions on the left bank of the Rhine he was in 1803 compensated by some of the former French territory round Mainz, and at the same time was raised to the dignity of Elector and Elector-William I. In 1806 he made a treaty of neutrality with Napoleon, but after the battle of Jena the latter, suspecting William's designs, occupied his country, and expelled him. Hesse-Cassel was then added to Jerome Bonaparte's new kingdom of Westphalia, but after the battle of Leipzig in 1813 the French were driven out and the elector restored. By the Vienna congress, where he intrigued in vain to be recognized as a king, several changes in the extent of his dominion were made. On his return to his sovereignty, William proposed to govt. his people a new and popular constitution, but just as the draft was ready to become law by his signature, he drew back, dissolved the diet, and continued to rule without again summoning it. His son, William II., who succeeded in 1821, pursued the same line of policy, and ruled on the government without reference to the diet. The discontent which this conduct excited was intensified by the elector's shameful connection with the countess of Reichenbach. Disaffection took place, and the elector, after attempting to pacify his people, appointed his son as regent in 1831, and withdrew to Frankfurt, where he died in 1847. The regent, becoming Elector Frederick-William I., styled by the proclamation of 1848, made many promises to the people, and carried some of them into effect, but on the reaction of 1850, which spread over all Germany, watched at the first pretext for returning to the former order of things. He attempted to have the diet dissolved without obtaining the consent of his chambers, but the opposition thus excited was so great that he was forced to retire to Wilhelmshaus, along with his very unpopular minister, Harnphang. He induced the diet of princes that assembled at Frankfurt to support him, and Austria and Bavaria took part, and Hesse-Cassel to enforce obedience. Prussia, in turn, immediately occupied the northern part of the country, and a civil war was briefly avoided by arrangement. The elector, however, scrupulously kept his policy, and the new states were not obtaining the consent of the chambers and the Government. In 1866 Hesse-Cassel joined Austria against Prussia. Prussian troops immediately overran the country, and the elector, with his chambers, was removed to the Prussian kingdom. The elector was carried a prisoner to Stettin, and was only released on resigning his claims to the throne of Hesse-Cassel. He died in 1875.

See Weymann, *König von Hessen und des Fürstenthums regent*, 1850; Roth, *Geschichte von Hessen-Kassel*, 1856; Gieseler, *Den Verfassungen-Länder in K. Hessen*, 1851; and works under Hesse.

HESSE-DARMSTADT, GRAND-DUCHY or, the actual Hesse of the present day, is a state of Germany situated on the Rhine and Main, between Prussia on the north and Baden on the south. It consists of two large and several small detached portions of territory. The more northerly of the large portions forms the province of Oberhessen, and is completely surrounded by Prussia. The other, divided by the Rhine into the provinces of Starkenburg and Rheinhessen, is bounded on the N. by Hesse Nassau, on the W. by the Rhine Palatinate, on the Rhine, Prussia, on the S. by Baden, and on the E. by Baden and Bavaria. The extent of the duchy is about 2965 square miles. Oberhessen is mountainous, having the Vogelsberg in the east with Tanfelsen (2879 feet) as the highest summit in the country, and the Haunsberg, a branch of the Taunus, in the south west. In the south-east of Starkenburg is the Odenwald. Rheinhessen is occupied by fertile hills. The chief rivers are the Rhine, Main, Neckar, Lahn, and Fulda, with their tributaries. There are no lakes, but mineral springs abound in all the provinces. The climate is pleasant and mild in the river valleys and plains, but severe on the heights, especially in Oberhessen. Besides the usual domestic animals, deer of various kinds, wild swine, foxes, martens, and others are found. Agriculture, including the breeding of horses and cattle, is actively encouraged by Government, and is the principal industry of the people. Forestry and vine growing are also important, the latter being practised almost exclusively in Rheinhessen. The principal crops are millet, buckwheat, oats, and potatoes, but rape (for oil), hemp, flax, tobacco,

and fruit are also cultivated. The manufactures embrace leather (enamelled and coloured), tobaccos, cigars, shoes, furniture, pocket books and similar goods, chemical, matches, machinery, and various textile fabrics. Mining is carried on chiefly in Oberhessen. Iron, copper, manganese, graphite, lignite, salt, marble, and clay are the principal minerals, which are worked for home consumption. In 1878 there were produced in Hesse 45,300 tons of lignite, 91,724 tons of iron ore, and 13,200 tons of salt, representing in value about \$62,100. Trade is tolerably important in Hesse. The following number of persons engaged in the various industries are taken from the industrial census of 1875.

—Agriculture, 222; fishermen, 65; miners, 1550; workers in stone, clay, glass, 4715; in metals, 8266; in machines, instruments, &c., 7202; in chemical industries, 2151; in lighting materials, soap, resins, &c., 1190; in textile industries, 8274; in paper and leather, 7600; in wood, 11,112; in food and drink, 19,923; in dress and washing, 21,629; in building, 1291; in polygraphic industries, 1291; in artistic industries, 412; in mercantile branches, 17,593; in conveyance, 2273; in lodging and boarding, 6016—total, 134,383. The people are well educated, of the recruits in 1878-79 only 21 per cent. were unable either to read or write. There is a university at Cassel, and the schools, ordinary, technical, and theological, throughout the country are very numerous. The Protestant religion predominates, though the Roman Catholic faith is also recognized by the state. Darmstadt is the capital, Offenbach is the chief manufacturing town, Mainz has perhaps the most active trade. The other chief towns are Alsfeld, Lauterbach, Friedberg, Jüngen, Biebrich, and Worms. The population in 1875 was 845,218. The government since 1820 has been a constitutional hereditary monarchy, assisted by two chambers, modified in 1856—the one of its members, mostly from among the nobility, the other of popular representatives, elected indirectly. The chambers meet most at least once a year three years. The ministry of three is responsible to the nation. Hesse is represented in the imperial federal council by 3 votes, and in the reichstag by 9. The annual revenue for the finance period 1876-78 was £272,375, and the expenditure £273,481. The estimated annual revenue for the period 1879-82 is £1,011,762, and the estimated expenditure £857,121. The public debt in 1879 was £2,041,397, chiefly mortgaged for railways. For additional statistics see GERMANY.

George I., youngest son of Philip the Magnanimous, received on his father's death in 1567 the appointment of *Kaiserlicher Rat*, and, selecting Darmstadt as his residence, became the founder of the Hesse-Darmstadt line. Additions to the territory were made both in his reign and in that of his son, Louis V. The landgraves, it is said, at first styled, suffered severely from war and its attendant famines and plagues. The Thirty Years' War, a war of succession with Hesse-Cassel, and the Seven Years' War, a debt of honor to its poverty. Louis V., who succeeded his father in 1701, involved it in further contests. Joining at first the allies against France, he was compelled in 1793 by the latter power to sign a treaty of neutrality. By the treaty of Lunenburg he gave up his possessions on the left bank of the Rhine, receiving in compensation six million marks. In 1806, in consequence of the French invasion of the Rhine, he assumed the title of grand duke. Louis V. of Hesse. After the battle of Leipzig in 1813, when Napoleon was defeated, Louis again joined the allies. By the decision of the Vienna congress in 1815 considerable changes in his dominions were made, but though he was forced to recognize the independence of Hesse-Rhomung, which since the beginning of the century had been incorporated with Hesse-Darmstadt, his title of grand duke was confirmed. William his country a good theatre for political liberty had been making itself apparent, and in 1820 the grand duke promulgated a new constitution. This was rejected by the people, and attempts were made in vain by successive diets to frame a constitution pleasing alike to the ruler and the ruled. Louis II.

succeeded his father in 1830. His policy in no degree lessened the popular discontent. His son Louis III., who succeeded in 1848, floundered by the events in Paris of that year, and by commotions in his own country, gave way a little, but under the reaction of 1850 he again adopted measures to that old state. Since that time, although no radical change has been effected, the liberal party in the state has been steadily gaining ground. In 1866 Hesse-Darmstadt supported Austria against Prussia, with the result that it had to pay a heavy indemnity and cede certain provinces.

A list of works on Hesse will be found in Weber's *Lebens- und Handbuch für Geschichte und Landeskunde von Hessen*, 1811; H. von Klenze, *Geschichte des Grossherzogthums Hessen*, 4 vols., 1844-51; Tschisch, *Hessens geologische und real-ökonomische Verhältnisse*, 1819-20; Hübner, *Geschichte des Grossherzogthums Hessen*, 1917; Dittmann, *Das Grossherzogthum Hessen als Provinzgebiet und Staat*, 1873; Volz, *Überblick des geologischen Baues des Grossherzogthums Hessen*, 1892; and works under Hesse.

HESSLE-ROMBURG, a former landgraviate of Germany, consisted of two parts, the province of Romburg von der Höhe, on the right bank of the Rhine, and the lordship of Merzenheim (added in 1815), on the left bank, to the north of Frankfurt-on-the-Main. It comprehended an area of 106 square miles, and its population in 1864 was 27,374. Romburg now forms part of the Prussian government district of Wiesbaden, and Merzenheim of the government district of Coblenz.

Hesse-Romburg was formed into a separate principality in 1696, in Frederick I. son of George of the Palatinate. By his treaty, it was divided into the parts Hesse-Romburg and Hesse-Rhinlangerhau, but the latter returned by inheritance to the original line in 1761. In the reign of Frederick V. (1751-1820) Hesse-Romburg was in 1806 in conflict with Hesse-Kassel, but that state was obliged by the Vienna congress to recognize the independence of Hesse-Romburg, which at the same time was increased by the district of Merzenheim. Frederick V. became a member of the German Confederation in 1817. After his death, his two sons successively filled the throne. The last, Ferdinand II. (1817-1858), granted a liberal constitution to his people, but in the revolution of 1848 and 49 he was deposed. On March 24, 1850, the principality devolved by inheritance to the grand duke of Hesse-Darmstadt, but in September of the same year that ruler was forced to cede it to Prussia, in consequence of having supported Austria in the Seven Weeks' War.

HESSIAN FLY, a name originally given in the United States in 1776 during the War of Independence to a small fly very destructive to wheat, supposed to have been brought over in straw by the Hessian troops employed on the British side. It is a species of *Ceomyzina*, described under the name of *C. autumnalis* by the American entomologist Say, and belonging to the Dipterous family *Ceomyzidae*, the numerous members of which produce galls, distortions, and other injuries in the plants they attack. It was often thought that this insect occurred in England, but the indigenous English wheat-midge, also very destructive, is an allied species, *Diptosis tritici*. A species found in Hungary and Germany, where it has committed great damage, has been supposed to be the true Hessian fly, which has also been recorded from Minorca and Naples. Collin notices its ravages in Silesia, and Kunster in Austria, and Kilsenbach (who identifies *C. aeralina*, Loew, with it) says it is much less common in Germany, and that it originally came from Europe. Nevertheless, many good authorities have considered that the destructive European fly is not identical with the North American insect, though closely allied to it, and of similar habits. In the United States this minute midge has been a deadly scourge at times, even to the extent of causing local famines. The female lays 20 or 30 eggs in a crevice of the leaf of the young plant, and the larva when hatched works there way between the leaf and the stalk, till they come to a joint, a little below the surface, where they remain, head down, sucking the sap, and to trap pupae enclosed in a covering, thus is known as the "flag-stump" condition. The injury occasioned is not detected until the plant grows higher. There are

two broods every year, one reaching the fly state in May, the other in August or early in September, as the fly only lives a few weeks, wheat that is sown so late as to come up until the second brood has disappeared escapes harm. The usual result of the attack is that small aborted ears only are formed, the few grains of which shrivel and will scarcely ripen, the straw also being of inferior quality. The perfect insect is smaller than the common gnat, which it somewhat resembles, and from which its size and more simple antennae distinguish it. The larva is spindle-shaped and reddish white, with the intestinal canal showing through the skin when full grown, they are about one-seventh of an inch long, and are provided with small hooks near the head, at this stage they group themselves in regular rings round the stem attacked. A very minute natural parasite, *Semiotus destructor*, belonging to the division *Pteromalidae* of the Hymenoptera family *Chalcididae* is, luckily for agriculturists, usually so plentiful as to be able to keep down the fly, on the larva and pupae of which its own larvae feed.

Besides the original account by Say (in the *Journal of the Academy of Natural Science*, Philadelphia, 1817), his countryman, Ph. A. B. Esch, has published a history of this insect in the *Ergebnisse der New York State Agricultural Society*, 1846, and in England the celebrated entomologist Kirby gave an account of it in the *Magazine of Natural History*, 1826. It is figured in the *American Naturalist*, vol. 1, p. 165. A map showing its distribution will be found in Hayden's Report of the United States Geological and Geographical Survey for 1875.

HESSUS, HELIUS EOBANUS (1488-1540), a distinguished German humanist of the 16th century, was born January 6, 1488, at Bockendorf near Frankenberg in Hesse. His family name is not known; the baptismal name Eoban he owed to a local saint, Hesus merely indicating the land of his origin, while the phenomenon Helius was assumed by himself partly with reference to the sun god, patron of poets, and partly also, it is said, with reference to the fact that he had been born on a Sunday. His early education was received in the monastery of Harna, where his father held a monial position, and afterwards at Frankenberg, in 1503 he entered the university of Erfurt, where in 1505 Crotus Rubianus and Ulrich von Hutten became his fellow-students and his firm friends. Though devoting himself enthusiastically to the composition of Latin verse, in which he soon became an acknowledged master, he was far from neglecting the other studies of that place, and shortly after his graduation he was named to a school at the post of rector of the St Severus school. Compelled by disturbances to leave Erfurt in 1510, he for five years led a somewhat wandering life, in the course of which he passed some time in Leipsac as a student of law, in 1515 he returned to his former post at Erfurt, and in 1516 became professor of belles-lettres. He was now prominently associated with Reuchlin, Peutingger, Mutianus, as well as with Crotus Rubianus and Hutten, and from the first he fully identified himself with the cause of Luther and the Reformation. In 1520 he went as teacher of rhetoric and poetry to Nuremberg, but in 1524 returned to Erfurt, whence in 1535 he was called to the chair of poetry and history in Marburg. There he died October 5, 1540.

Hessus was generally regarded by his contemporaries both in Germany and elsewhere as the foremost Latin poet of the age, "if Erasmus was the modern Cicero, Eoban was Virgil and Ovid." His most popular works were a translation into Latin dactylic hexameter, which passed through more than forty editions, and Latin hexameter translations of Theocritus and of the *Iliad*. He also published *Silvae*, a collection of idylls, epigrams, and occasional pieces, and a series of Christian *Horodes*, in imitation of the Roman poet. His works were edited by his friend Josellum Griesener, who also published his Life (1558). See the monographs of Hess (*His Hesus, ein Lehrer u. Dichter lebte aus der Reformationszeit*, 1880), Scherzsch (*U. E. Hesus, ein Lebensbild aus der Reformationszeit*, 1874), and Krause (*U. E. Hesus, sein Leben u. seine Werke*, 1879), also Stasius, *Ulrich von Hutten* (1858; 2d ed 1872, Engl transl 1874).

HESTIA, a Greek goddess, who is probably the latest in origin of the greater deities. She seems to belong to a particular stage in the advance of civilization, and to embody the religious sanction that confirmed the social system then reached. When we compare her worship with that of Agni, the nearest parallel in the Vedic period, we see that the Greeks made this advance after they had separated from the Aryan conquerors of India. Agni is invoked in the *Rig Veda* as the brother, friend, and helper of men, as dwelling with them and mediating between them and the gods. But beyond this Hestia is the hearth-fire as the centre of an association, wider or narrower, which meets in common at the hearth. She is not mentioned in Homer, in the *Odyssey* sometimes one swears by Zeus, the table and the hearth, i. e., by Zeus as the god of the family both in its external relation of hospitality and its internal unity toward its own hearth. Hence we have the Zeus *τῶν οἴκων* *τῶν οἴκων*, *τῶν οἴκων*. The former of these two ideas is too delicate and fine even to become more than a mere aspect of Zeus, but the second gradually formed itself into a distinct worship, in which the already existing worship of the fire was merged. The fact that Hestia is not mentioned in Homer shows that her worship was not so universally acknowledged at the time which these poems reveal to us. Perhaps we may see in the connexion of the Latin Juno and Vesta at Lavinium a relic of the original connexion of the two, and the fact that the worship of this same goddess under the same name (they are only two forms of the feminine of the passive participle of the root *vas*, *vas*) is found in Latium and Greece affords strong evidence of a specially close connexion between the two races. We find therefore in Hestia ideas of the old pre-Greek worship, she is the altar-fire, presiding over all sacrifices, and sharing in the honours of all the gods. The opening sacrifice was offered to Hestia, to her at the sacrificial meal the first and the last libations were poured. The fire of Hestia was always kept burning, or if by any mischance it was extinguished, only sacred fire made by friction, or got direct from the sun, might be used to rekindle it (see Kühn, *Herakleia*). But beyond this she is the goddess of the family union, the personification of the idea of home (see Welcker, *Gr. Gott.*, ii. 694), the protectress along with Zeus of the suppliants who fled for refuge to the hearth. To her therefore is ascribed the art of housebuilding. Hestia and Hermes are often united as the representatives of home and private life on the one hand, and of all business and outdoor life on the other. The city union, moreover, is just the family union on a large scale, it has its centre in the prytaneum, where the common hearth fire round which the magistrates meet is always burning, and where the sacred rites that sanctify the council of city life are performed. From this fire, as the representative of the life of the city, was taken the fire wherewith that on the hearth of a new colony was kindled. As patroness of the deliberations held in the prytaneum, Hestia is surnamed *Βουλευαία*. Even larger unions than the city had their central fire in Tegea, was the Hestia of the Arcadians, and it is probable that the Achæans had theirs at Arginum. In the later mystic philosophy Hestia became the hearth of the universe, the eternal fire at the centre of the world.

As Hestia had her home in the prytaneum, special temples to her rarely occur. There was one in *Homoneia*, where the only symbol of the goddess was a fire always burning on the hearth. We also hear of her house at Olympia. Her statue stood in the prytaneum at Athens beside that of Pæon. Though many statues of the Roman Vesta are preserved, more or less based on the Greek conception of Hestia, yet no really Greek representation of the goddess has come down to us.

HESEYCHASTS (*ἡσυχασταί* or *ἡσυχαστῆς*, also called *ἀσκησάδωχοι*, Umbilicatus, and sometimes referred to as Euclytes, Massalians, or Palamites), a quietistic sect which arose among the monks of the Greek Church, and especially of Mount Athos, during the later period of the Byzantine empire, and owing to various adventitious circumstances, came into great prominence politically and ecclesiastically for a few years about the middle of the 11th century. Their opinion and practice will be best represented in the words of one of their only teachers (quoted by Gibbon, *Decline and Fall*, c. 63) — "When thou art alone in thy cell shut thy door, and seat thyself in a corner, raise thy mind above all things vain and transitory, reject thy heart and clasp on thy breast, turn thine eyes and thy thoughts towards the middle of thy belly, the region of the navel, and search the place of the heart, the seat of the soul. At first all will be dark and comfortable, but if thou persevere day and night, thou wilt feel an ineffable joy, and no sooner has the soul discovered the place of the heart than it is involved in a mystic and ethereal light." About the year 1337 this Heseychasm, the affinity of which with certain well-known forms of Oriental mysticism is obvious, attracted the attention of the learned and versatile Basilian, a Calabrian monk, who at that time held the office of abbot in the Basilian monastery of St. Saviour's in Constantinople, and who had visited the fastitudes of Mount Athos on a tour of inspection. And much that he disapproved, what he specially took exception to as heretical and blasphemous, was the doctrine contained in it as to the nature of this divine light, the fruition of which was the supposed reward of Heseychastic contemplation. It was maintained to be the pure and perfect essence of God Himself, that eternal light which had been manifested to the disciples on Mount Tabor at the transfiguration. This Basilian held to be polytheistic, inasmuch as it postulated two eternal substances, a visible and invisible God. On the Heseychastic side the controversy was taken up by Gregory Palamas, afterwards archbishop of Thessalonica, who laboured to establish a distinction between eternal *θεός* and eternal *δύναμις*. In 1341 the dispute came before a synod held at Constantinople, the decision of which no doubt was to a large extent determined by the excessive veneration in which the writings of the pseudo-Dionysius were held in the Eastern Church, was adverse to Basilian, who in consequence returned to Calabria, and afterwards became bishop of Hierace in the Italian communion. Three other synods in relation to the same subject were subsequently held, and at the last of these, held in 1351 under the presidency of the emperor John Cantacuzenus, the unqualified light of Mount Tabor was established as an article of faith for the Greeks, who ever since have been ready to recognize it as an additional ground of separation from the Roman Church. The contemporary Latinus, Cantacuzenus and Nicephorus Gregora have both dealt very copiously with this subject, which is also more or less discussed in all the church histories. See Engelhardt's article on the Ascetics and Heseychasts in *Heinrich's Zeitschrift für Theol.*, viii. 48, and the account of the Heseychasts in *Heizog's Enchiridion*. It may be mentioned that in the time of Justinian the word Heseychast was applied to monks in general simply as descriptive of their quiet and contemplative character of their pursuits.

HESEYCHIUS was a grammarian of Alexandria, as we learn from a letter prefixed to his great work. From the fact that he was apparently unknown to Heseychius the Milesian and other writers of the time of Justinian, M. Schmidt considers that he must have flourished later than 530 A.D. On the other hand he cannot have been later than 643 A.D., when the school of Alexandria was scattered by the Saracen conquest. Many old Greek words occur

ing in his book show that he belonged to this late period Wölke (*Re Mus.* 11 209) places him in the latter part of the 14th century. Belonging to the school of Alexandria, he was probably a pagan, and the explanations of words from Gregory Nazianzen and other Christian writers (*glossæ variæ*) are interpolations of a later time. He has left a Greek dictionary, containing a copious list of peculiar words, forms, and phrases, with an explanation of their meaning, and often with a reference to the author who used them or to the district of Greece where they were current.

Hence the book is of great value to the student of the Greek dialects, while in the restoration of the text of the classical authors generally, and particularly of such writers as Zephyrius and Theophrastus, who used many unusual words, its value can hardly be exaggerated. The explanations given of many epithets and phrases reveal to us numberless facts about religion and social life, which are of the highest importance in the study of antiquities. In a prefatory letter addressed to his friend Eudæmus (who is probably the Eudæmus Scholasticus mentioned in the *Phylologus* *Magnum* and elsewhere), Hesychius mentions that his work is based on the lexicon of Diogenianus, but that he has also used similar works by Aristarchus, Apollon, Hylædæus, &c. (about whom see M. Schmidt's edition, vol. 1.) The text is very corrupt, and the order of the words has often been disturbed. There is no doubt that many interpolations, besides the Christian glosses, have been made.

HETTSTADT, or **HETSTEDT**, a town of Prussian Saxony, in the circle of Mansfeld, and the government district of Merseburg, is situated on both banks of the Wipper, about 23 miles N.W. of Halle. It is the seat of a court of justice, and has manufactures of machinery, pinpoints, and artificial manure. The population in 1870 was 5098. In the neighbourhood are mines of argentiferous copper, and the surrounding district and villages are occupied with woolen and similar works. Silver and sulphur are also the other chief products, nickel and gold are also found in small quantities. Hettstadt is mentioned as early as 1016, in 1220 it possessed a castle, and in 1840 it received the privileges of a town. When the countship of Mansfeld was sequestered, Hettstadt came into the possession of the Saxons, from whom it passed to the Prussians in 1815.

HEUGELIN, THOMAS VON (1821-1876), an eminent African and Arctic traveller, was born 20th March 1824 at Hirschland near Leonberg in Württemberg, and died at Stuttgart, 5th November 1876. His father was a Protestant pastor, and he was originally trained to be a mining engineer, but his own early ambition was to contribute to scientific progress by his personal explorations, and he prepared himself for his task by careful and multifarious discipline, studying the natural sciences, and more particularly zoology, acquiring the more serviceable of the modern languages, strengthening his physique by gymnastic exercises, and learning to use with equal skill his pencil and his gun. Supplied with funds by his mother's liberality, Heugelin went to Egypt in 1851, and till 1865 the north-eastern regions of Africa were the main scene of his labours. In 1852 he accompanied Dr Reitz, the Austrian consul at Khartum, in his fatal journey to Abyssinia, in 1853, having been appointed Dr Reitz's successor in the consulate, he visited Kordofan and the lower course of the White Nile, and in 1857, on his return after about two years' absence in Europe, he was commissioned by the grand-duke Ferdinand Maximilian of Austria to explore the countries along the west coast of the Red Sea. From the latter part of 1858 to the latter part of 1860 he was again in Europe, but in 1861 he was placed at the head of the Vogel search expedition, which included Munzinger,

Steindach, Kinzelbach, &c., and was expected to make its way to Wadai. Having reached Mai scheich, however, the explorers broke up into three parties, Heugelin turning along with Steindach and Schubert in the direction of Adon, Gundar, and the Galla lands. At Khartum they joined Miss Tanne's party, and proceeded to Lake Rey and the Kosangia river, but Steindach died on 10th April 1863, and Heugelin was compelled by sickness to retracé his steps. He returned to Europe in 1865. In 1870 and 1871 he made a valuable series of explorations in Spitzbergen and Novaya Zemlya, but 1875 found him again in North-East Africa, in the country of the Beni Amer and Habab. An invitation from the khedive took him abroad again in 1876, but receiving no definite appointment he returned to Europe. Later in the same year he was engaged in preparing for an exploration of the island of Socotra, when he was suddenly carried off by inflammation of the lungs. He was buried beside Mauch, the African traveller, and a statue has been erected over his grave.

His principal works are *Systematische Uebersicht des Vogel Nord-Afrika's*, 1855, *Besuchen in Nordost-Afrika's*, 1852-1853 (Götting, 1857), *Reise Uebersicht des Geschehens in Nordost-Afrika's* (Vienna, 1857), *Reise nach Abessinien, den Galla-Ländern, &c.*, 1861-62 (Jena, 1868), *Reise in das Gebiet des Nijvers Nil*, 1862-1864 (Leipzig, 1866), *Reisen nach dem Nordpolgebiet*, 1870-71 (Bismarck, 1872-74), *Reise nach dem Nordpolgebiet*, 1870-71 (Bismarck, 1872-74), *Reise nach dem Nordpolgebiet*, 1870-71 (Bismarck, 1872-74), *Reise in Nordost-Afrika* (Bismarck, 1877, &c.). It is principally his zoological, and more especially his ornithological, labours that Heugelin has taken rank as an independent authority. A list of the more important of his numerous contributions to *Reisens in Ostafrika's* will be found in that serial for 1877 at the close of the zoological notice.

HEUSCH, **WILHELM** or **GUILLELM** DE, a landscape painter in the 17th century at Utrecht. The dates of this artist's birth and death are unknown. Nothing certain is recorded of him except that he resided over the guild of Utrecht, whilst Cornelis Poelenburg, Jan Both, and Jan Weenix formed the council of that body, in 1649. According to the majority of historians, Heusch was born in 1638, and was taught by Jan Both. But each of these statements seems open to doubt, and although it is obvious that the style of Heusch is identical with that of Both, it may be that the two masters during their travels in Italy fell under the influence of Claude Lorraine, whose "Arcadian" at they imitated. Heusch certainly painted the same effects of evening in wide expanses of country varied by rock formations and lofty thin leaved abscissances as Both. There is little to distinguish one master from the other, except that of the two Both is perhaps the more delicate colourist. The guild of Utrecht in the middle of the 17th century was composed of artists who clung faithfully to each other. Poelenburg, who painted figures for Jan Both, did the same duty for Heusch. Sometimes Heusch sketched landscapes for the bathpitches of Molenaar. The most important examples of Heusch are in the galleries of the Hague and Rotterdam, in the Belvedere at Vienna, the Stadel at Frankfurt, and the Louvre. His pictures are signed with the full name, beginning with a monogram combining a G (for Guilielm), D, and H. Heusch's etchings, of which thirteen are known, are also in the character of those of Both. After Guilielm there also flourished at Utrecht his nephew, Jacob de Heusch, who signs like his uncle, substituting an initial J for the initial G. He was born at Utrecht in 1657, learnt drawing from his uncle, and travelled early to Rome, where he acquired friends and patrons for whom he executed pictures after his return. He settled for a time at Berlin, but finally retired to Utrecht, where he died in 1701. Jacob was an "Arcadian," like his relative, and an imitator of Both, and he chiefly painted Italian harbour views. But his pictures are now scarce. Two of his canvases, the Ponte Rotto at Rome, in the Brunswick Gallery, and a lake harbour with

shipping in the Lichtenstein collection at Vienna, are dated 1696. A harbour with a tower and distant mountains, in the Belvedere at Vienna, was executed in 1699. Other examples may be found in English private galleries, in the Hermitage of St Petersburg, and the museums of Rouen and Montpellier.

HEYELIUS, HWEIT, HOWIT, HEWELLS, or HOWELLS, JOHANN (1611–1687), astronomer, was born at Dantzic on January 28, 1611, and died there on January 28, 1687 (see ASTRONOMY, vol. 11 p. 754).

HEXHAM, a market-town of England, county of Northumberland, is situated on the south bank of the river Tyne, crossed there by a handsome stone bridge of nine arches, 20 miles west from Newcastle and 86 east from Carlisle, and on the line of railway connecting those towns. It is somewhat irregularly built, and consists chiefly of several narrow streets diverging from the market place, a spacious square. Its defects in architecture and arrangement are, however, compensated for by its pleasant situation and the imposing remains of the old priory church. This church, begun by Wilfrid in 674, and completed by Acon, his successor, remained unimpaired till 875, when every part of the monastery but the stone work was destroyed by the Danes. It was built of stones used in an earlier work, and many of them bear Roman inscriptions. Originally in dimensions and splendour it was unsurpassed on this side of the Alps, and doubtless had no small influence on ecclesiastical architecture in various parts of England. The building as it occurred in the 15th century consisted of nave and transepts, choir and aisle, and a massive central tower, but the nave was burned by the Scots in 1296, and has never been rebuilt. The style is Early English with Transition details. The crypt, discovered in 1726, is a fine example of Saxon architecture, of which there appear also to be some traces in the choir. Among the interesting old monuments which have been collected in the transepts is a sculptured stone slab of Oswulf, king of Northumbria, of the date 783. To the west of the church there are still some remains of the conventual buildings. Near the market place there are two old castellated towers. A vessel containing about 8000 Saxon coins was discovered in the churchyard in 1832. The "Skel," formerly the park of the monks, is now used as a promenade, and from an eminence within its bounds a fine view is obtained. Hexham possesses a new town hall and coin exchange, erected in 1866 in the Italian style, and a large board school. A hydropathic establishment has recently been opened. Leather gloves are the principal manufacture of the town, and it has tanneries, wool staples, yards, a brewery, and an iron and brass foundry. In the neighbourhood there are extensive market gardens and nurseries. The population of the township in 1871 was 5381, and of the parish 6437.

Hexham is supposed by some to have been the Avalonnum of the Romans, but although in all probability it was a Roman station, the similarity in the names is too slight to establish the identity. By the Saxons it was called Hedon. In 875 the town was the neighbouring stream. Wilfrid, who founded the monastery and died in 678, received from Queen Etheldreda a grant of the town and a large surrounding tract of country. In 881 the southern portion of Hexham was formed into the diocese of Hexham, which comprised the county of Durham and the greater part of Northumberland. In 821 Hexham was united to the diocese of Lindisfarne, after which it formed part of Durham, then of York until 1857, when it was restored to Durham. In 875 the town was plundered by the Danes and the monastery destroyed. In 1138 the monastery was plundered by the Scots, and in 1296 they again attacked the town and burned the nave of the conventual church. In the reign of Henry VIII. the last prior of Hexham was in 1536 hanged at the gate of the monastery for being concerned in the rebellion called the Pilgrimage of Grace.

See the old *History of the Church of Hexham*, by Prior Richard, *Roman Hexham and Hexham Church in Ethelred's Alliance*, *Northumbria*, vol. v., Wright's *History of Hexham*, 1828, *The Priory of*

Hexham, its Churches, Endowments, and Annals, edited for the Society by James Raine, 1864–65, *Hexham, its History and its Antiquities*, Hexham, 1879.

HEYDEN, JAN VAN DER, was born at Goudum in 1637, and died at Amsterdam on the 12th of September 1713. He was an architectural landscape painter, a contemporary of Hobbema and Jacob Ruysdael, with the advantage, which they lacked, of a certain professional versatility, for, whilst they painted admirable pictures and sketched, he varied the practice of art with the study of mechanics, improved the fire engine, and died superintendent of the lighting and director of the firemen's company at Amsterdam. Till 1672 he painted in painting with Adam van der Velde. After Adam's death, and probably because of the loss which that event entailed upon him, he accepted the office, to which allusion has just been made. At no period of artistic activity had the system of division of labour been more fully or more constantly applied to art than it was in Holland towards the close of the 17th century. Van der Heyden, who was perfect as an architectural draughtsman in so far as he painted the outside of buildings, and thoroughly mastered linear perspective, seldom turned his hand to the delineation of anything but brick houses and churches in street and square, or towns along canals, or "moated granges," common in his native country. He was a talented man, had seen the Hague, Ghent and Brussels, and had ascended the Rhine past Xanten to Cologne, where he copied over and over again the town and tower of the great cathedral. But he cared nothing for hill or vale, or stream or wood. He could reproduce the row of bricks in a square of Dutch houses sparkling in the sun, or stunted trees and lines of dwellings varied by sloops, all in light or thrown into passing shadow by moving cloud. He had the art of painting microscopically without loss of breadth or keeping. But he could draw neither man nor boat, nor ships nor cars, and this was his disadvantage. His good genius under these circumstances was Adam van der Velde, who enlivened his compositions with spirited figures, and the joint labour of both is a delicate, nimble, transparent work, radiant with glow and atmospheric, and most pleasant to look at. Almost all Van der Heyden's pieces are inscribed with his name alone, as if Van der Velde had been but a sleeping partner in his work. Like Hensche, he formed the first letters of his name into a monogrammatic misalliance. Very few of his pictures are dated. One, a street in a Dutch town, of 1666, is in the Hope collection in London. Two of 1667, a bullock on a canal, huddled with houses casting their reflections into the water, and the town-house at Amsterdam, are in the galleries of the Hague and Florence. Another view of the dam and town-hall at Amsterdam, dated 1668, is in the Louvre. A church and houses in the museum of Dresden is inscribed 1673. In all there are seventy or more of Van der Heyden's works fairly accessible to the public—those which are least so being chiefly in English private collections. Eight capital examples are in the Hermitage at St Petersburg, two of which are views in Cologne. Four are in the London National Gallery, four at Amsterdam and Dresden. Munich and Cassel have two apiece, and two very fine ones are in Buckingham Palace. The rest are in public and private galleries in Vienna, Paris, Frankfurt, and Karlsruhe.

HEYDUKE. See HADYK.

HEYLIN, FRAKE (1599–1662), an historical and polemical writer, born at Bedford, Oxfordshire, 29th November 1599, was the second son of Henry Heylin, gentleman, who belonged to an old Montgomeryshire family. Heung of a studious turn of mind, Heylin was entered at Hall, Oxford, in 1613, was of Magdalen College, 1615, B.A., July 1617, M.A., 1620, B.D., 1629, D.D., 1633. In July

1618 he began to read college lectures on cosmography (i. e., geography) with such acceptance that his associates made him fellow of Magdalen. The lectures, under the title of *Metacosmos*, were published in 1621, and many editions of this useful book, each somewhat enlarged, subsequently appeared, until scarcely any scholar's library was without a copy. In 1626 he published his observations on a journey to France. This book—which was frequently republished—

Southey termed "one of our liveliest books of travel in its lighter parts, and one of the wisest and most replete with information that was ever written by a young man." After obtaining the patronage of Laud, whose life he wrote, Heylin was made chaplain to Charles I. His legendary and learned *History of St George of Cappadocia* procured for him the rectory of Hemmingford, Hants, his hearty attachment to the High-Anglican party brought many other preferments, and his analysis of Prynne's *Histionomastix* was rewarded by the rectory of Ishp. He was also made a prebendary of Westminster (9th November 1631), and wrote to the chapter (1637), and subsequently said down. Here he was the bitter opponent of the rule of Bishop Williams, the commendatory dean. With great ardour Heylin entered into the religious controversies which preceded the war, being equally hostile to the Puritan element within and without the church. He was consequently singled out for punishment by the committees of the Long Parliament, who deprived him of benefices worth £200, and heavily fined him. An amusing anecdote he tells affords proof of his popularity in London, and at the same time shows how his *Cosmography* was appreciated. As he passed along the street a fellow "shouldered" him with the remark, "Geography is better than Divinity." For seven years, he says, his name was in almost every label. He returned to his Hampshire parsonage of Altonford until 1647, many disturbed him. Robbed these of his library, valued at £1000, and his property, he went to Oxford, where from 1st June 1643 he edited *Mercator's Atlas*, a valuable but violent now-sheet which greatly annoyed the Parliamentarians. His *Britannus Populatus*, written against L'Etalange (who wittily retorted that a pulpit should be "no stinker"), refers to his sufferings and hardships. The necessary quiet for his literary pursuits was ultimately found at Lady's Court, Abingdon, whence were dated several books and pamphlets against those of his own communion. His opinions were not so unpopulous as he is represented by the Puritans and other controversialists in which Usher, Fuller, Baxter, and Waddington were concerned. His works, all more or less marred by political or theological animosity, were upwards of fifty in number, and they comprise in *History of Episcopacy*, of the Reformation, and of the Presbyterians, with a useful *Help to English History*. Some of his merit also came from his active pen, and his posthumous memorial of Bishop Wren was published by the Caxton Society in 1851. Heylin was a diligent writer and investigator, a good ecclesiastical lawyer, and had his learning always at command. His principles, to which he was honestly attached, were defended with ability, but his efforts to uphold the church passed unobserved at the Revolution. His sight began to fail him, yet he rejoiced that his "old bad eyes" had seen the king's return. Upon that event he preached a jubilee sermon in Westminster Abbey to a great audience, 20th May 1661. He died on 8th May in the following year, and was buried two days after under his son-dan's seat.

Lives of Heylin were written by Dr John Burnard, his son-in-law, and by George Vernon. Burnard's work was very carefully republished, with notes, in the *History of the Reformation*, published, 1849, by the E. E. Society and History Society.

HEYNE, CHRISTIAN GOTTLIEB (1729–1812), one of the most distinguished critics and archæologists of the modern

school of which Ebnest and Gieseler were the founders, was born on the 25th of September 1729, in a suburb of the city of Chemnitz in Saxony, where his father, who had been compelled by some religious persecutions to abandon his native country of Silesia, earned a precarious support for his family by exercising the trade of a weaver. It was only by the liberality of his godfathers that Heyne was enabled to obtain his primary instruction in the elementary school of Chemnitz, and afterwards to prosecute his classical studies in the gymnasium of that city. In 1748 he entered the university of Leipzig, with the professed intention of studying for the legal profession. There he was so warmly supported by those on whose assistance he relied that he was frequently in want even of the common necessaries of life, and was sometimes indebted for food to the generosity of a maid servant in the house where he lodged. In this situation, without even the hope of future distinction, he continued to struggle on against every difficulty and disappointment in the acquisition of knowledge. For six months he is said to have allowed only two nights in the week to sleep, and he was at the same time forced to endure his godfather's reproaches for negligence in the prosecution of his studies. His distress had almost amounted to despair, when he procured the situation of tutor in the family of a French merchant resident in Leipzig. He was thus enabled to continue his studies, though with much interruption, the emolument of his appointment being sufficient to support him in what was at least comparative comfort. Under Ebnest he was initiated into the criticism of the classical authors, from the prelections of the celebrated Bach he acquired a competent knowledge of Roman jurisprudence, and by Christian, who lectured on archæology, his attention was strongly directed to the works of ancient art. Even after he had finished his studies at the university, he was exposed for many years to all the accumulated distresses of poverty and neglect. The first situation he was able to procure was that of copyist in the library of Count von Buhl in Dresden, with a salary of somewhat less than twenty pounds sterling, which he obtained in the year 1753. From the necessity of adding something to this scanty pittance, he was forced to employ himself in the drudgery of translation, and, besides some French novels, he rendered into German the Greek romance of Chastillon. He published his first edition of *Thésaurus* in 1756, and in 1756 he published the last year of the Seven Years' War broke out. Dresden was entered, and the Saxon archives seized, the Buhl ministry fell, and Heyne was once more in a state of absolute destitution. In 1757 he was offered a tutorship in the household of Frau von Schenborg, and there he first became acquainted with Teresa Woss, whom he subsequently married. In January 1759 he accompanied his pupil to the university of Wittenberg, at which more than a year was spent in the study of philosophy and German history, but from which he was driven in 1760 by the Prussian cannon. The bombardment of Dresden (to which city he had previously returned) on July 18, 1760, destroyed not only his humble lodging but also all his worldly possessions, which included amongst other valuable papers an almost finished edition of Lucian based on a valuable codex of the Dresden Library. In the summer of 1761 he married, although still without any fixed means of support, and for some time he found it necessary wholly to suspend his literary pursuits that he might devote himself to the duties of the office of land-steward, to which he had been charitably appointed in the household of the Baron von Loben in Lusatz. He was enabled, however, to return to Dresden in the end of 1762, where he was commissioned by Lippert to prepare the Latin text of the third volume of his *Zeitschriften*. At length, in the commencement of the year 1768, Heyne's

ment met with its reward, and a new and illustrious career was opened to him. In the death of Johann Matthias Gesner at Göttingen in 1761, the appointment to the vacant chair had been first offered to Enoch, who, however, declined leaving the university of Leipzig, but proposed Ruhnken of Leyden or Saxe of Utrecht for the appointment. Ruhnken likewise refused it, but having been strongly impressed with the taste and learning displayed by the editor of Tibullus and Epictetus, he advised Munichhausen, the Hanoverian minister and principal curator of the university of Göttingen, to bestow the professorship on Heyne, whose merit, though known to few, he was confident would do honour to the choice. The minister had the good sense to acquiesce in the recommendation of this great scholar, and Heyne, after some delay, became professor of eloquence in Göttingen. Though his appointments were at first few and his emoluments inconsiderable, these were gradually augmented in proportion as his usefulness was proved, and his growing celebrity rendered it an object with the other Governments of Germany to secure the services of so distinguished a scholar. He refused the most advantageous and honourable overtures from Cassel, Berlin, and Dresden. As professor, principal librarian, member of the Royal Society, and chief editor of the *Gedächtnis Auserwählter*, and still more by his publications, he greatly contributed to raise the university of Göttingen to the distinguished rank it still holds among the universities of Europe. After a long and useful career, graced with all the distinctions which in Germany are conferred on literary eminence, he died, full of years and honour, on the 14th of July 1812.

Besides Tibullus (1755, 4th ed. by Wundtlich in 1817) and the *Enchiridion of Epictetus* (1760, 2d ed. 1776), he edited Virgil (1767–75, new ed. by Wigan, 1830–44), Pindar (1771, 1817), the *Bibliotheca Graeca* of Apollodorus (1782, 2d ed. 1803), and the *Thucydides* (1802)—all illustrated with copious commentaries. His *Opuscula Académica*, in six vols. (1785–1812), contain a mass of notes that amply render up all dissertations, of which the most valuable are those respecting the colonies of Greece and the antiquities of Rhene in art and history. He left also a great number of papers on almost every subject of antiquity, more especially on ancient mythology, among the *Commentationes Societatis Regiae Göttingensis*. His *Antiquarische Lefzule*, in two vols., comprise a valuable collection of essays connected with the history of ancient art. His contributions to the *Magazin für die Kunst* are valued by Herken to have been between 7000 and 8000 numbers. In the earlier part of his life he translated, or rather wrote and, a great part of the *Universal History*, by Heumann, *Hynde's Biographie* (1810), which forms the basis of the interesting essay by Carlyle, originally published in the *Foreign Review* (1838), and now reprinted in his *Miscellaneous*, vol. i.

HEYWOOD, a manufacturing town of Lancashire, is situated on the Roch, and on the Lancashire and Yorkshire Railway, 3 miles east of Bury and the same distance south-west of Rochdale. It possesses several handsome churches and chapels, among which may be mentioned St Luke's church, erected in 1860, with a tall spire and a peal of bells. The other principal buildings are the national school, the mechanics' institute, the new Conservative club-house, and the market hall. A new park—the Queen's Park—purchased and laid out at the cost of £11,000 with money which devolved to Her Majesty in right of her duchy and county palatine of Lancaster, was publicly opened on the 2d of August 1879. Heywood Hall in the neighbourhood of the town was at one time the residence of Peter Heywood, who contributed to the discovery of the Gunpowder Plot. Heywood owes its rise to the enterprise of the Peels, its first manufacturers having been introduced by the father of the first Sir Robert Peel. It is an important seat of the cotton manufacture, in connection with which it has upwards of fifty factories, and there are in addition power-loom factories, iron foundries, boiler works, and railway wagon works. Coal is wrought extensively in the neighbourhood. The population in 1871 was 21,348.

HEYWOOD, JOHN (c. 1500–1569), sometimes styled “the Epigrammatist,” was born, it is not known in what year, at North Mims near St Albans. He was educated at Oxford, and afterwards made the acquaintance of Sir Thomas More, who introduced him at court. His skill in music and his inexhaustible fund of ready wit made him a special favourite of Henry VIII, and afterwards of his daughter Mary. On the accession of Elizabeth, Heywood, who was a zealous Catholic, retired to Malmes in Belgium, where he died in 1569. A collection of his works was published in 1562.

The longest single composition is the allegorical work, written in the octave stanza, entitled *The Spider and the Fly* (1514), in which the fly is the Roman Catholic and the spider the Protestant, while Queen Mary is represented by the housewife with her broom (the spider), overhauling the commands of her insect (Christ) and his insects (the church). It has been justly characterized by Walton as dull, tedious, and tuffling. Of greater literary interest are the *Interludes* (*A Play between John the Husband, 2nd of the 17th*, and *St John the Priest, A merry Play between the Pardoner and the Friar, the Clerk and Nephew*), *Prize*, *The play called the Four Ps*, a new and very merry *Interlude of a Peasants*, in *Pardners*, a *Voluntary*, and a *Pastoral*, *A Play of Unchastity and Nobility*, *A Play of Love*, *A Play of the Witches* (which form a connecting link between the old morities and the modern drama), and were extremely popular in their day. They generally represent some ludicrous incident of a homely kind in a style of the broadest farce, but in their way of play considerable skill and talent. Other works of his were in a comic poem in long verse, entitled *A Judgment collection in praise the number of all the Proverbs in the English tongue* (compiled in a matter concerning two marriages), and three collections of *Epigrams*.

HEYWOOD, THOMAS, a voluminous dramatist and miscellaneous author of the 16th and 17th centuries, was born in Lancashire and was educated at Cambridge, where he became a fellow of Peterhouse. The dates of his birth and death are alike unknown, and the few facts of his life that are preserved have been gleaned chiefly from his own writings. He is mentioned in the MS book of Henslowe as having written a book on play for the Lord Admiral's Company in October 1599, and from the same source we learn that in 1598 he was regularly engaged as a player and a sharer in that company. In the preface to *The English Traveller*, written in 1633, he describes himself as having had “an entire hand or at least a managing in two hundred and twenty plays.” Of this number, which probably afterwards were considerably exceeded, that we find him still writing in 1610, and indeed his list could hardly have been more than 1677, only three and twenty survive, but they amply attest that he had the right to concentrate his powers, he might easily have imitated with the Marston, Ford, and others of his great contemporaries “Heywood,” says Charles Lamb, “is a sort of prose Shakespeare, his scenes are to the full as natural and affecting.” His facility and variety are shown without a parallel, his fancy was inexhaustible, and his invention never at a loss, but he delighted to co-operate in what he called “many accidents, intermixed with apt and witty jests,” or in other words, in the broadest and coarsest farce. His best pieces, such as *A Woman Killed with Kindness*, *Fortune by Land and Sea*, *The English Traveller*, and *The Fair Maid of the West*, he chiefly in the department of what has been called the domestic drama.

Besides his dramatic work, which was partly included in the “Shakespeare Society,” and was published in complete edition of six vols. with notes and illustrations in 1874, he is the author of *True Discourse of the English Traveller* (1599), a comic interlude, and a collection of many plays, which were first printed in 1633, and with an universal chronicle from the creation until the present time. “An Apology for John Heywood,” first published in 1632, *Translation in nine books of the works of Euripides* (1633), *England's Virgils*, *for the use and instruction of the youth*, *from the Cradle to the Crown* (1631), *The Life and Death of the* *Angels* (1635), *Plasunt Discourses and Instructions of the* *Angels*, *and* *The Life of Mother Beata and Sister* (1642).

of the animals which hibernate during the winter are liable to fall into a similar state at intervals during mild weather, and Dr Marshall Hall has applied the term "Diurnation" to the day-sleep of bats, which he regards as precisely analogous to hibernation.

MAMMALS.—Although comparatively few mammals hibernate, the phenomena of hibernation and similar conditions have been better studied in this class than in any other. Dr Marshall Hall has laid down the principle that the amount of respiration is inversely as the degree of irritability of the muscular fibre. Every gradation may be met with between ordinary sleep, the imperfect or abnormal hibernation of some animals, and the profound hibernation of others, in which all the functions of life are almost suspended. Such a condition is always accompanied by reduced respiration, and increased irritability of the muscular fibre. If the respiration is reduced without this irritability being increased, death results from toxæmia and asphyxia, whereas, if the respiration is increased simultaneously with increased irritability (as when an animal is aroused too suddenly), death likewise results from too great stimulation of the vital powers. The well-known danger of suddenly awakening a patient from a state of somnambulism is doubtless due to a similar cause.

Hibernation, however, is a physiological condition, and not produced simply by cold, though it is favoured by it, because cold induces sleep, which may afterwards pass into hibernation. It is an error to suppose that hibernating animals are capable of sustaining any amount of cold, though their capacity of doing so must vary according to their species and to the climate which they inhabit. They always seek secure hiding-places when they may be protected from too great a degree of cold, as well as from interference. During hibernation the temperature of their bodies sinks to a point corresponding nearly to that of the surrounding atmosphere, but if they are exposed to an unusual amount of cold, they are first awakened by it, and then sink into a fatal torpor like other animals. Many hibernating animals perish in this manner during severe winters.

Respiration being almost suspended during hibernation, the maintenance of vitality depends almost wholly on the action of the heart, which will continue for a long time after an hibernating animal has been decapitated. Animals may also be placed in carbonic acid or under water for several hours, without injury, when in this condition, though they would die in a very few minutes if they were in their normal state.

Man.—Long continued suspension of consciousness in man, whether voluntary or otherwise, is rare in temperate climates, but it is more frequent in India, where some religious ascetics are stated on unimpeachable authority to possess the power of throwing themselves into a state closely resembling hibernation for an indefinite period. Many curious cases have been recorded by Mr Brand in his small treatise on *Human Hibernation*, published in 1850, the most celebrated of which is that of a fakir who was actually buried alive at Lahore, in 1837, in the presence of Runjeet Singh and Sir Claude Wade, and who was dug up and restored to consciousness several months afterwards, after every precaution had been taken to prevent any one from disturbing the grave in the interval.

Bats.—Dr Marshall Hall says that the hibernating bat never wakes at all, except from warmth or excitement, and that the digestive functions are suspended to a far greater degree than in the dormouse or hedgehog. Respiration is also suspended, and when the animal is disturbed it quickly subsides again into total quiescence, after a few feeble respirations. It is to be regretted that Dr Hall has not stated to which species of bat his remarks refer, as the

habits of the various species differ. Bats, or at least in autumn, according to the species, they retire to caves, hollow trees, and similar hiding places, where they cluster together, hanging head downwards by their hinder claws, and clinging to each other, as well as to the walls and sides of their retreat, so that a great number can crowd themselves into an amazingly small space. Although such assemblies frequently consist of more than one species, yet the various species do not all retire to their winter quarters at the same period, the noctule is rarely seen abroad later than July, whereas the pipistrelli may be seen flying on mild evenings almost every month in the year. It is only natural to suppose that the hibernation of the former species is much more profound than that of the latter, which doubtless feeds in winter as well as summer, for though insects are far less numerous in winter than in summer, yet some species appear only at that season of the year.

Beas and Badgers.—These animals retire to winter quarters in northern climates, and pass the greater part of their time in sleep, but the brown bear and badger do not fall into a state of genuine hibernation. When the bear retires for the winter, he is very fat, and it is said that the black bear will not hibernate if this is not the case. Digestion is suspended, and his intestines become stopped up with an indigestible mass chiefly composed of pine leaves, which is now discharged all spring. The bears of Europe and Siberia are very dangerous if disturbed during the winter, but the black bear of America can scarcely be aroused from his torpor, which there is thus reason to believe is a state of true hibernation, differing from that in which the former species passes the winter.

Hedgehog.—This animal hibernates more completely than almost any other. In the autumn it retires to a hole among rocks or under the roots of a tree, where it remains for the winter, seldom or never awakening till spring, and of course taking no food until then. If a sleeping hedgehog is disturbed, it merely stirs, and then coils itself up more closely, but if a hibernating hedgehog is disturbed with, it takes a deep convulsive gasp, followed by a few feeble respirations, and then by total quiescence. The tenrec, an allied animal found in Madagascar, sleeps for three months in its burrow during the hottest period of the year.

Rodentia.—Several animals belonging to this order hibernate more or less completely, among which we may mention the hamster, the porcupine, the dormouse, the squirrel, and the marmot. Several of these awake at intervals to feed, and therefore lay up a store of provisions before they retire, although they all become very fat before winter. Other species of this order hibernate so perfectly, or only occasionally, like the hedgehog, which will lie beneath deep snow in a small cavity, just large enough to receive her body, for some weeks unharmed. But this is not true hibernation, as respiration is maintained during the whole time, a small air-hole being always kept open by the warm breath of the animal. In a similar manner ships (though belonging to a very different order of animals) have sometimes been buried in snow drifts in Scotland for several weeks without sustaining any injury. The dormouse and mole hibernates in the strict sense of the term, but will sleep at intervals for several days together during mild weather. When a *Myotis*, an allied animal inhabiting Africa, was brought to Europe, it hibernated as if this was its normal habit. Whether it actually is in its native country is not known, but its hibernating in Europe shows a greater power of adapting itself to changed conditions of life than we should have been inclined to suspect.

AVES AND FISHES.—It was formerly supposed that various species of swallows hibernated, and it was even asserted that the sand martin was accustomed to bury itself

in the mud at the bottom of the water; but this has long been regarded as an exploded error. For the hibernation of fish, compare the article on ICHTHYOLOGY.

AMPHIBIA AND REPTILIA.—All the animals belonging to these classes hibernate in cold or temperate climates. Land tortoises bury themselves in holes in the ground, and fresh-water tortoises in the banks or at the bottom of lakes and rivers. Lizards and snakes retire to holes in trees, under stones, or among dead leaves, where many species congregate in large numbers, and pass the winter closely entwined, and in a still more torpid condition than that of the hibernating mammals, their digestion and respiration being entirely suspended. Many tortoises, crocodiles, and serpents bury themselves in mud in both South America and Africa, and estivate in the hard-baked ground during the dry season of the year. When the viper is disturbed during the winter its bite is harmless; but this is not the case with the venomous serpents which estivate in tropical countries.

Frogs generally hibernates in masses in the mud at the bottom of the water, and if awakened from hibernation by warmth can remain eight times longer under water without drowning than frogs in the breeding season. We should hardly expect the habits of such an animal as the frog to be greatly affected by domestication, but Professor Bell was acquainted with a gentleman living at Kingston, whose kitchen was built on the banks of the Thames, and whose servants made a pet of a frog which had his hole in the skirting. It was unnecessary for the frog to hibernate, and instead of doing so he came out of his hole every evening to bask before the kitchen fire for three successive winters. It is impossible to say how long frogs and toads may continue to retain a dormant life, if the mud in which they bury themselves should become hardens around them during hibernation. Too many circumstantial accounts of the discovery of live toads imbedded in solid rock, and even in coal, have been published to allow us to dismiss them all as fabulous, notwithstanding the difficulty and obscurity in which this subject is still involved.

MOLLUSCA.—Many species hibernate. The land-snails bury themselves in the ground, or conceal themselves under the bark of trees, in holes in walls, or even in the stems of large umbelliferous plants. They close the mouth of the shell with a calcareous plate, technically called an epiphragm, which they secrete by means of their mantle, and which is perforated by a small hole to admit the air. In winter they bury themselves with the head upwards, and do not grow at all during the winter; but while growing they bury themselves in summer, with the head downwards, at occasional intervals, for several days together, and then grow very rapidly. Snails are not considered in season at Paris till after the first frost, when they are closed with a white epiphragm. In dry weather, and during the heat of summer, snails also close their shells with an epiphragm, to protect themselves from drought, but this covering is thinner than that which they construct during the winter. In the British Museum is preserved the shell of a specimen of *Helix desertorum*, from Egypt, which revived after having been gummed to a board for four years in the Museum, and lived for two years afterwards. Other instances of the revival of land-shell after a still longer period are equally well authenticated. Some species retire to winter quarters earlier than others, and their hibernation, which ranges from 30 to 110 during summer, ceases entirely in winter. Slugs also bury themselves in

Helix Desertorum.

the ground, and become torpid during frosts or droughts, but it is doubtful whether their condition is that of genuine hibernation. The fresh-water mussels (*Anodonta*) hibernate before the close of autumn, and bury themselves in the mud till the beginning of spring. It is believed that many of the marine *Mollusca* also hibernate, but very little is known of their habits at present.

INSECTA.—Most of the insects which pass the winter as larvae or perfect insects hibernate during the period that they can obtain no food. Larvae which are full grown in autumn frequently lie dormant during the winter, and do not assume the pupa state till spring. In the case of insects which have more than one brood in the year, the last brood generally hibernates, sometimes retiring to winter quarters quite early in the autumn, while the perfect insects of the previous brood are still flying about, and while the weather is still fine and warm. Insects which hibernate in the perfect state do not pair till spring, and are probably not fully developed till after hibernation. Hive-bees probably do not hibernate, and it is well known that they require food during the winter. It is asserted that the aphides, on whose sweet secretion ants chiefly subsist in inclement weather, become torpid at exactly the same low temperature as the ants themselves.

CONCLUDING REMARKS.—The seeds of many plants, and the eggs of many of the lower forms of animal life, may remain dormant for years in cold or dry climates, until heat or moisture awakes them to vitality. Many plants die down in winter, the roots remaining in the ground, while many trees then shed their leaves, the sap retiring to the roots. Similar phenomena take place in tropical countries during the hot, dry season, wherever the amount of humidity in the atmosphere is insufficient to maintain a perennial vegetation during the year. These phenomena in the vegetable world are regarded as analogous to those of hibernation in animals, and the term "hibernation of plants" is sometimes applied to them.

HICKES, GEORGE (1642-1715), a learned English divine of the nonjuring party, and an eminent Anglo-Saxon scholar, was born at Newsham near Thirsk, Yorkshire, on June 20, 1642. In 1659 he entered St John's College, Oxford, whence after the Restoration he removed first to Magdalen College and subsequently to Magdalen Hall. In 1694 he was chosen fellow of Lincoln College, and in the following year proceeded M.A. On his return from a Continental tour in 1673 he graduated in divinity, and in 1675 he was appointed rector of St Ebbe's, Oxford; in the following year he as private chaplain accompanied the duke of Lauderdale, the royal commissioner, to Scotland; and shortly afterwards he received the degree of D.D. from the university of Glasgow. In 1680 he became vicar of All Hallows, Barking, London; and after having been made chaplain to the king in 1681, he was in 1683 promoted to the deanery of Worcester. At the revolution of 1688, having declined to take the oath of allegiance to William and Mary, he was first suspended and afterwards deprived;—he meanwhile affecting to this cathedral doors a "protestation and claim of right" that he was, and still did "continue to be, the only rightful and legal dean of this cathedral church of Worcester." After remaining some time in concealment in London, he was employed by Sancroft and the other nonjurors on a mission to the Continent on matters connected with the proposed action of his party relative to the continuance of their episcopal succession; upon his return he was himself consecrated by Lloyd, White, and

Turner suffragan bishop of Thetford in 1694. His later years were largely occupied in controversies the interest of which has now almost wholly passed away; but to them was owed the two works which constitute his chief claim to an enduring reputation, the learned *Institutiones Grammaticae Anglo-Saxonicae et Mosco-Gothicae* (1689), and *Linguarum veterum Septentrionalium Thesaurus grammatico-criticus et archaeologicus* (1703-1705). In 1713 he united with Bishops Campbell and Gadderar to consecrate Jeremy Collier, Samuel Hawes, and Nathaniel Spinkes to be bishops in the nonjuring church. He died December 16, 1715.

Even apart from the two were already mentioned, Hickes was a very voluminous and laborious author. His earliest performances, which were anonymous, were suggested by contemporary events in Scotland that gave him great satisfaction,—the execution of Mitchell on a charge of having been implicated in the murder of Archbishop Sharp, and that of Kid and King, Presbyterian ministers, "for high treason and rebellion" (*Ravillasson's Letters*, 1678; *The Spirit of Popery speaking out of the Mouths of Phanatical Protestants*, 1685). In his *Jovius* (an answer to Johnson's *Julian the Apostate*, 1683), he endeavoured to show that the Roman empire was not hereditary, and that the Christians under Julian had recognized the duty of passive obedience. His *Two Treatises*, one "On the Christian Priesthood" and the other "On the Dignity of the Episcopal Order," originally published in 1707, have been more than once reprinted, and form three volumes of the *Library of Anglo-Catholic Theology* (1847). In 1705 and 1710 were published *Collections of Controversial and Ecclesiastical History*, and in 1728 a volume of *Posthumous Discourses*. Other treatises, such as the *Apologetical Vindication of the Church of England*, are to be met with in Gibson's *Preservatives against Popery*.

HICKORY. The hickory trees are natives of North America, and belong to the genus *Carya* of botanists. They are closely allied to the walnuts (*Juglans*), the chief or at least one very obvious difference being that, whilst in *Carya* the husk which covers the shell of the nut separates into four valves, in *Juglans* it consists of but one piece, which bursts irregularly. The hickory trees are of lofty growth, and are held in high estimation, both on account of their durable timber and from the excellent nuts which some of the species produce. The timber is both strong and heavy, and remarkable for its extreme elasticity, but it is not much used either for shipbuilding or for architectural purposes, as it decays rapidly when exposed to heat and moisture, and is peculiarly subject to the attacks of worms. It is very extensively employed in manufacturing musket stocks, axle-trees, screws, rake teeth, the bows of yokes, the wooden rings used on the rigging of vessels, chair backs, axe-handles, whip-handles, and other purposes requiring great strength and elasticity. Its principal use in America is for hoop-making; and when it is remembered how large a proportion of the productions of the United States is packed in barrels, some estimate may be formed of the consumption of hoops and of the consequent demand for hickory wood, which is the only American wood found perfectly fit for that purpose.

The wood of the hickory is of great value as fuel, on account of the brilliancy with which it burns and the ardent heat which it gives out, the charcoal being heavy, compact, and long-lived. The species which furnish the best wood are *Carya alba* (shell-bark hickory), *C. tomentosa* (mockernut), *C. oliviformis* (pecan or pecan nut), and *C. porcina* (pig-nut), that of the last-named, on account of its extreme tenacity, being preferred for axle-trees and axe-handles. The wood of *C. alba* splits very easily and is very elastic, so that it is much used for making whip-handles and baskets; the whip-handles are greatly esteemed for their suppleness, and considerable numbers of them are annually imported into England. The wood of this species is also used in the neighbourhood of New York and Philadelphia for making the back bows of Windsor chairs. The timber of *C. amara* and *C. aquatica* is considered to be of inferior quality.

Most of the hickories form fine-looking noble trees of from 60 to 90 feet in height, with straight, symmetrical

trunks, well-balanced ample heads, and bold, handsome, pinnated foliage. When confined in the forest they shoot up 50 or 60 feet without branches, but when standing alone they expand into a fine head, and produce a lofty round headed pyramid of foliage. They have, observes Downing, all the qualities which are necessary to constitute fine graceful park trees, and are justly entitled to a place in every considerable plantation. The most ornamental of the

FIG. 1.—Shell-bark Hickory (*Carya alba*) in flower (nat. size). 1, Female flower (nat. size); 2, portion of male inflorescence (nat. size).

species are *C. oliviformis*, *C. alba*, and *C. porcina*, the last two also producing delicious nuts, and being worthy of cultivation for their fruit alone.

The husk of the hickory nut, as already stated, breaks up into four equal valves or separates into four equal portions in the upper part, while the nut itself is tolerably even on the surface, but has four or more blunt angles in its transverse outline. The hickory nuts of the American markets are the produce of *C. alba*, which is called the

FIG. 2.—1, Fruit of *Carya alba*; 2, hickory nut; 3, cross section of nut; 4, vertical section of the seed. All natural size.

shell-bark hickory because of the roughness of its bark, which becomes loosened from the trunk in long scales bending outwards at the extremities and adhering only by the middle. The nuts are much esteemed in all parts of the States, and are exported in considerable quantities to Europe. The pecan-nut, which comes from the Western States, are from an inch to an inch and a half long, smooth, cylindrical, pointed at the ends, and thin-shelled, with the kernels full, not like those of most of the hickories divided by partitions, and of delicate and agreeable flavour. The thick-shelled fruits of the pig-nut are generally left on the ground for swine, squirrels, &c., to devour. In *C. amara* the kernel is so bitter that even the squirrels refuse to eat it.

HICKS, ELIAS (1748-1830), founder of the Hekmites, one of the two great sects into which the Society of Friends in America has since 1828 been divided (see *QUAKERS*), was born at Hempstead, Long Island, on March 10, 1748. During the earlier part of his life he followed the business of a carpenter and housebuilder, but this occupation he latterly exchanged for that of farming. Related in a Quaker family, he began, when about twenty-seven years of age, to "have openings leading to the ministry," and to be "deeply engaged for the right administration of discipline and order in the church." In the intervals of business, accordingly, he began to visit the meetings and families of Friends throughout an extensive range of country, and soon he established a very considerable reputation as an efficient and popular itinerant preacher. His first literary effort seems to have been made no earlier than 1811, when he published *Observations on Slavery*; those doctrinal divergences from the received orthodox creed of the Friends, by which his name was brought into the prominence it now possesses, appear not to have become visible until 1820, when he wrote a *Doctrinal Epistle* (published in 1824), which was followed by much controversy, and resulted in 1828 in the formal separation from the Hekmites of those more orthodox Quaker brethren. The positions involved were, justly considered to affect the fundamental doctrines of the Christian religion, such as those of the Trinity, the Incarnation, and the supreme authority of Scripture. Hicks died at Teicho, Long Island, on February 27, 1830. See *Journal of the Life and Labors of Elias Hicks* (Philadelphia, 1828).

HIERAPOLIS Of the many cities in the Greek world bearing this name the following are the most important.

1. A city of Syria, Cynhestia, situated on some hills about 10 miles south-west from the junction of the Euphrates and the Sajra. Besides the natural strength of its position, it was important as lying on the line of intercourse between Northern Syria and Mesopotamia, and was always a great trading city. Its early history is quite unknown. It is not mentioned during the Assyrian wars; in this part of Syria (see Sayce, *Academy*, October 1876) Abul Fairs asserts that Josiah was defeated there by Pharaoh Necho (611 B.C.) on his march towards Carchemish, but according to 2 Chron. xxv. 20 the battle took place at Carchemish, which lay on the Euphrates a little further north on the site of the modern Jebelbi, or Jorabbi, and probably Abul Fairs confounded the two cities. The same confusion perhaps has caused the statement of Ammianus that Hierapolis was identical with Ninus Vetus, on the Euphrates. Jebelbi is clearly a corruption of Hierapolis, by which name therefore Carchemish must at some time have been styled by the Greeks, but it is surprising to find two great cities of the same name so near one another. No proof exists that Hierapolis was an important city before the time of the Seleucids, and Professor Sayce suggests that it then succeeded to the trade and name of the older city, which had now decayed. Its original name is given in Greek as *Babylon*, which points back to a form *Bambyg* or *Mambog*, while the Syrian form is given by Ptolemy as *Mabog*, s.e., *Mabog* for *Mambog*. The romance of trade by which this name has become naturalized in many European languages deserves a passing notice. As the city lay on the highway to the East, cotton and silk were important branches of its trade. Probably cotton plantations existed there in old times, and after the cultivation of silk was introduced to western Asia in the time of the Sassanians, large groves of mulberry trees surrounded the city. The name *Mambe* was afterwards confounded with the Persian word *pambe*, silk, and the Greek form *Βαμβύκη* also was similarly mixed up with the

word *Babyl*,¹ which originally denoted the *fly* supposed to spin on trees the cotton or silk (for the two substances were confused by the Greeks and Romans) which men then gathered off the trees (*Vulg. Georg.* i. 121). Hence the "Bombycene vestes" of the Roman writers, while the city itself is called "Bombycena urbs." In Asia cotton seems to have been known as a distinct article, and was named after the city which was the chief seat of its manufacture, as muslin is from Mosul. By the crusaders the stuff and the name were carried to Europe, and the latter exists in English in the form "bombazine." The Syrian goddess Atargatis, called by the Greeks Derceto, a personification of the native power worshipped under different names over the whole of western Asia, had one of her most famous temples in the city, and perhaps *Mambe* may have been a local name of the goddess. Hence in the 3d century B.C., when, under the Seleucid kings, *Bambyce* became a great Greek city and the most important station between Antioch and Seleucia, it was called *Hierapolis* of Hieropolis. The latter form is found on coins, the former is used in classical literature. The coinage of Hierapolis begins under the Seleucids. The Antonine coins, probably for commercial reasons, imitate closely the coins of Antioch. The temple was plundered by Cissus on his Parthian expedition (53 B.C.). Under Diocletian or Constantine, Hierapolis became the capital of the new province of Euphratesia, a name which soon gave place to the older name *Comagenae*. As paganism decayed, Hierapolis ceased to be the sacred city, and recovered its ancient name, at the same time its importance and population declined. In the time of Julian, who concentrated there the Roman troops for the great Parthian campaign, it was still one of the greatest cities of Syria, but under Justinian, who made some attempt to restore it, great part of its area was a desert, and the once strong fortifications were so decayed that the place was not defensible against the Parthian king Chosroes. As the Arab conquest it passed into the hands of the caliphs. Haroun-al-Raschid (786-808) restored it and strengthened its walls, and it is mentioned about 1150 by Edrisi as a strong city. As the empire of the caliphs dwindled, *Mambyce* became a frontier post in the struggle between Christians and Mahometans, and its possession carried with it the rule in this part of Syria. The emperor Romanus Diogenes captured it in his gallant struggle against the Turks (1068). Recaptured by the Seljuk Turks, it soon afterwards fell into the power of the crusaders, until it was stormed by Saladin (1178). It was for some time the headquarters of the Mongol host under Hulegu Khan, and, as with many other Syrian cities, its desolation dates from that time. The name which still exists called *Kara Bamboche* or *Bayuk Mambyce*, have been described by Pococke and others, and most carefully by Chesney (*Euphrates Expedition*, i. 420).

² *Shabo* (xvi. p. 748) confuses this Hierapolis with Edessa in Mesopotamia. A very full account of the city to supplement the brief outline here given may be found in Ritter, *Erkenntnis*, x. 1041-65.

2. A city in Phrygia, at the junction of the Lycus and Meander, on the road from Apamea to Sardis. In it there were warm springs which had and still have a remarkable power of forming incrustations. Its name Hierapolis is due to the sanctity conferred on it by these hot springs, and by the Plutonium, a small cave under a projecting rock, from which there constantly emanated a dark vapour deadly to man and beast (*Shabo*, xii. 629, Vitruv., viii. 3, *Apuleius, De Mundo*, p. 65). In reference to this we find sometimes on its coins Pluto carrying off Proserpine.

¹ *Babyl* is borrowed from the Persian word (*Benfey, Wurzel*, i. 118), though the form it has taken in Greek is influenced by the word *Babylon* to buzz. It is used by Aristotle, &c., to denote a great fond in Asia Minor, which has certainly nothing to do with silk.

not inherit the kingdom of God, that his reputation as a heistic chiefly depends.

HERO, the name of two rulers of Syracuse.

HERO I, displacing his infant nephew, succeeded his famous brother Gelon as tyrant of Syracuse in 478 B.C. His rule was more tyrannical than Gelon's had been, and his jealousy of his more popular brother Polyzelus (who was at the head of the army, and had married Gelon's widow Domarette, daughter of Theon of Argintum) ended in an open quarrel, in which Theon sided with Polyzelus. The brothers, however, were reconciled, and Hero married Theon's sister. From the slight information extant regarding Hero, his influence seems to have been very great. He removed the inhabitants of Naxos and Catania to Leontini, and peopled Catania, which he renamed *Atina*, with Dorians. He was also an important factor in the history of Argintum, of Rhegium, and of Locri, and he saved the Greeks of Campania from the Etruscans, whose naval power he destroyed by his great victory at Cuma (474 B.C.). Though despotic in his rule, he was a hearty patron of literature, and numbered among his friends such names as *Archylus*, *Bacchylides*, *Epicharmus*, *Simonides*, and *Pindar*—the last of whom celebrated his victories in the Olympic games. He died at Catania in 467 B.C.

HERO II, king of Sicily, was the illegitimate son of a Syracusan mother. Hierocles, who claimed descent from Gelon (see *GELON*). His birth must have taken place before the year 506 B.C. On the departure of Pyrrhus from Sicily (in 275 or end of 276 B.C.), the Syracusan army and citizens alike marked their approval of Hero's military and popular qualities by placing him at the head of the troops, and he materially strengthened his position by marrying the daughter of Leptines, the leading citizen. A body of Campanian mercenaries, who had been employed by King Agathocles of Syracuse, had taken the designation of *Mamertines*, and occupied Messina. From this stronghold they harassed the Syracusans. Hero led his army against them, and in the engagement that ensued he abandoned to the enemy his mercenary troops, whose sullen disposition he distrusted, and reheated with the rest of his soldiers to Syracuse. There he raised a native force, with which he drove the Mamertines into the corner of the island, defeated them in a pitched battle, and was prevented from capturing Messina only by Carthaginian intervention. His grateful countrymen then chose him king (270 B.C.). In 264 he again returned to the attack, and the Mamertines called in the aid of Rome. Hero at once joined the Punic leader Hannu, who had newly landed in Sicily, but being defeated by the consul Appius Claudius, he withdrew to Syracuse. Pleaded by the Roman forces, he was in 263 compelled to conclude a treaty with Rome, by which he was to rule over the south-west of Sicily and the eastern coast to Tauromenium. From this time till his death in 216 he remained the fast friend of Rome, rendering frequent and valuable service during the First Punic War by supplying men, material, and provisions. Presents were sent him in acknowledgment of these good offices, but the strong desire of the Romans to occupy Sicily prevented his receiving any accession of territory at the close of the war. When the Second Punic War broke out, he was faithful as ever, joined his fleet to that of Scipio, and offered supplies of food and clothing. At home, he was a wise and just ruler. He retained the republican senate, and governed as a constitutional monarch. Munificent in his gifts to foreigners—*veriness*—his presents to Olympia, to the Rhodians, to King Ptolemy, and above all to the Romans—and in the erection of public buildings within his own domain, he was exceedingly simple in his personal tastes, he wore a citizen's dress, and was not attended by guards. So wise were his financial arrangements that they were re-

tained by the Romans after the reduction of Sicily. He kept up a powerful fleet for defensive purposes, and employed his famous kinsman *Archimedes* in the construction of those engines that, at a later date, played so important a part during the siege of Syracuse by the Romans. His only son, Gelon, predeceased him, and he was succeeded by his grandson Hieronymus.

HEROCLÆS, a Roman proconsul, first of Bithynia and afterwards of Alexandria, flourished during the reign of Diocletian (284-305 A.D.), and is said to have been the instigator of the fierce persecution of the Christians under Galerius Caesar in 303. He was a man of considerable intellectual culture, and wrote a work entitled *λόγοι θεολογικοὶ πρὸς τὴν Χριστιανισμῶν* in two books, in which he endeavored to persuade the Christians that their sacred books were full of contradictions, and that in moral influence and miraculous power Christ was inferior to Apollonius of Tyana. For our knowledge of the nature of this treatise, which has not come down to our times, we are dependent on Lactantius (*Instit. Div.*, v, 2), and still more on Eusebius, who is the author of a refutation entitled *ἀντιπρὸς τὸν ἑρῶκλῆα*.

HEROCLÆS, a Neo-Platonic writer of the 5th century A.D., was apparently a native of Alexandria. He was born most probably about the beginning of the 5th century, studied under the celebrated Neo-Platonist Plotinich at Athens, and taught for some years in his native town. He seems to have been banished from Alexandria and to have taken up his abode in Constantinople, where he endured some persecution for his religious opinions. His death must be referred to the closing decade of the 5th century, probably about 480. The only complete work of his which has come down to us is the commentary on the great Pythagorean *Carmina Aranea*, but several other writings, especially one on Providence or Foreknowledge, are quoted or referred to by Plotinus and Iamblichus. The commentary contains several remarkable utterances, and is written with much elegance. Philosophy is there regarded in its practical aspect, as a discipline for purifying or elevating the mind by inculcating virtue and leading to truth. The most curious doctrines contained in the work are those bearing on providence and the human soul. The activity of the Divine Being, the supreme God, although eternal and all-reaching, is viewed as extending specially or immediately only to spiritual existences, or rather to the genera of such existences. The individuals are not directly the objects of divine foreknowledge, perfect freedom of individual will is maintained. All that is preordained is but the connection between volitions and their natural consequences. As regards the human soul, the teaching of Hierocles in the main resembles Neo-Pythagoreanism. He states the doctrine of transmigration and pre-existence, holds that there is an ethereal body which is purified by trial along with the soul, and regards the world as the means by which judgment upon the past actions of the individual spirit is carried out.

The earliest edition of the commentary is the Latin translation by Ambrase in 1474, the Greek text was first given by Oudinus in 1688. The fragments of the works on Providence and Fate were published in 1698 by Moellius. Later editions of all that is preserved appeared in 1864-5, 1878, and 1709. The commentary alone has been edited by Ascham (1743), by Wolf (1710), by Gaisford in his edition of *Silvestri* (1850), and finally by Mullach (1868). The text book entitled *Λογικὴ* (edited by Schaefer, 1768, and Eberhard, 1869), though frequently attributed to this author, is certainly the work of a later hand. The most complete information regarding Hierocles is to be found in Mullach's edition, and in the relative portions of his *Fragmenta Phil. Græcæ* (Amst., 1860, p. 408 ff.) Cf. Zeller, *Phil. d. Griechen* (2d ed.), ii, 2, pp. 681-7.

HIEROGLYPHICS

INTRODUCTION

THE term hieroglyphics is used, with others, by Greek and Latin writers to describe the sacred characters of the ancient Egyptian language in its classical phase. It is used by the moderns for various systems of writing in which figures of objects take the place of conventional signs. This article is limited to an account of Egyptian hieroglyphics, with some notice of the derived systems called hieratic and demotic.

It is no longer necessary in an article like the present to give a history of the interpretation of hieroglyphics and a sketch of the grammar of ancient Egyptian. What students need is a statement of the main results, as to the Egyptian characters themselves and a systematic bibliography.

The written language of the ancient Egyptians remained the same from the date of the earliest monuments (Third Dynasty) until the age of the Ptolemaic Kings (B.C. 300), when a vulgar dialect expressing the common speech is first found in written documents. Then, if not earlier, the older phase of the language became the classical Egyptian, sometimes called the sacred dialect, to distinguish it from the vulgar dialect. The classical Egyptian was used almost as late as the fall of paganism generally for all documents but legal and commercial ones, for which the vulgar dialect was used.¹

It is necessary to observe that although Egyptian is not proved to be a Semitic language, it contains in its oldest known form undoubted Semitic elements, both in structure and roots. The constant comparison with the Semitic languages which is here necessary is therefore not merely employed for the sake of the analogies that may be discovered, but on the ground of partial affinity, which, however, must not be strained.

It must also be borne in mind that the grammar of ancient Egyptian is in its infancy. We know many of its principal facts, but we do not know them accurately. For instance, we know the forms of many tenses of the verb, and can perhaps place these tenses in groups, as past, present, and future, but we cannot define the different senses of the various tenses of each group. Similarly, in Coptic we do not always know the shades of difference within a group of tenses. It may be that in Coptic these shades have disappeared through the decay of the language, but it would be rash to affirm this of the classical Egyptian. Thus this essential part of the grammar will not be understood until the verb has been thoroughly worked downwards from the oldest texts through the classical language, then through the demotic, and then the Coptic, and again in inverted order from the Coptic upwards. The same labor has to be performed for the whole grammar in each of the three phases of the language, before we can speak with any certainty of Egyptian grammar. This is said in no disparagement of the admirable work already done, but as a necessary caution to the student.

¹ As early as the time of the Ptolemaic differences of dialect due to difference of speech in Upper and Lower Egypt had crept into correspondence (Budge, *Gram. Hist.*, 93). Ultimately vulgar forms and constructions are distinctly traceable in the sacred language (Id. *loc. cit.*, *Id. Grev. Inschr.*, 94, 95). There is also natural change due to development or decay on both, and artificial changes due to fashion. Modifications of grammatical forms and the growth of style are instances of vital changes, and the direct borrowing of Semitic words by the scribes of the Ptolemies, and what is still more remarkable, the actual Semitization of Egyptian words, are examples of artificial changes (Hasepe, *Hist.*, 387, 388).

The following sections are abridged (to p. 800, end of section on "Secret Writing"), with additions and modifications, which are noted by them being included in parentheses, from M. de Rougé's *Chrestomathie Égyptienne*, Abtégé Grammatical.

THE SYSTEMS OF WRITING

The elements of Egyptian writing are composed of a certain number of actual objects, natural or artificial, imitated by drawing or engraving.

Egyptian writing falls into three systems—(1) hieroglyphic, (2) hieratic, (3) demotic or enchorial, the hieratic being a simplified form of hieroglyphic, and the demotic of hieratic. The complete designing of hieroglyphics required skill and time. They thus came to be reduced in writing to the simplest forms which retained the leading characteristics. These were called by Champollion linear hieroglyphics. The linear forms not lending themselves with sufficient readiness to very rapid writing, a further abbreviation was made, by which the forms became almost conventional,—the original type usually ceasing to be immediately recognizable. This cursive system Champollion called hieratic. The demotic writing is a new abbreviation of the hieratic, it gradually departs so far from the original types as to appear to consist of arbitrary signs.

Hieroglyphics are written either in horizontal lines or vertical columns, and are ordinarily read from the right. The heads of animals and the like show from what direction to begin reading. Hieratic and demotic are written from right to left, in horizontal lines. In very early times hieratic is sometimes written in vertical columns.

(The hieroglyphic is a lapidary system, the hieratic and demotic purely systems for common writing. Consequently the hieroglyphic is the most difficult of the three to read, as the engraver or painter paid great attention to the symmetrical appearance of each group of signs, and grammatical forms were hence often omitted. In hieratic and demotic the signs follow each other without interruption of the natural order, and the grammatical forms are usually given, and even more fully.)

CHARACTERS IN RELATION TO THEIR USE IN WRITING

Egyptian writing is composed of a mixture of signs of two distinct classes—(1) ideographic, each sign representing an idea, (2) phonetic, representing a sound, either (a) a simple articulation (alphabetic) or (b) a complete sound, i.e., a complete syllable (syllabic). The two classes were combined according to fixed rules in writing words.

IDEOGRAPHIC SIGNS

This class may be best divided into (a) representative signs and (b) symbolic (typical).

The representative signs exactly express the idea of the object of which they present an image, as ♂ a star.

The symbolic (typical) signs represent an idea by the aid of certain analogies which the mind sees between the symbol and the idea attached to it. A simple symbol presents a single object, as the sun ☉, when used in the symbolic sense "day." A symbol is complex when uniting more objects than one to convey to the mind a single idea, thus a star suspended beneath the celestial vault  represented "night." Under

complex signs should be placed figures of divinities in which the human form has special addresses or insignia.

The value of ideographic signs may be discovered in various ways. The representative signs only need that the thing represented should be determined. The symbolic signs are often (at first, sometimes) explained by classical authors, they may also be explained by careful study of bilingual documents, as the Rosetta Stone (and the Decree of Canopus). The sense, and more certainly the reading, can be discovered by an exact knowledge of the words written by phonetic combined with ideographic signs, and above all by the variants allowed in writing the same word with signs of different classes. (The result may be thus tabulated)

Ideographic Signs		Phonetic Signs	
Representative	Symbolic	Alphabetic	Syllabic
Di Bugeisli in his <i>Gram</i> <i>Hûb</i> (p. 3) gives the following scheme			
Phonetic Signs		Ideographic Signs	
Alphabetic	Syllabic	Special	General

Here the ideographic signs are classed, not according to their nature but according to their use, which will be later noticed. M de Rougé's seems the more logical classification.)

PHONETIC SIGNS

As the phonetic signs represent either (α) a simple articulation or (β) a complete sound, *i.e.*, a complete syllable, the hieroglyphic method comprehends (a) an alphabet and (β) a syllabary.

Champollion held that the alphabet originated from giving to each object the phonetic value of the initial of its name: thus the mouth "◀" "no" would become "n". This probable principle cannot now be tested for a great part of the alphabet, probably in consequence of the loss of many moniac words.

The alphabet of the Greek and Roman periods presents a great number of homophones for each articulation. The more we advance towards antiquity the more the method simplifies, and the alphabet of primitive times admits but a very small number of homophones. Dr Lepsius (*Lehrb. d. Hierogl.*) first scientifically treated this distinction.

ARTICULATIONS OF THE EGYPTIAN LANGUAGE

The determination of the exact number of articulations which the series distinguished in the Egyptian language presents great difficulties. Comparison with the articulations of languages which occur in bilingual texts cannot give sufficiently precise results, for the shades of sound are far from being the same in the languages thus placed in juxtaposition. The Romans and Greeks had many letters which, though quite distinct in their languages, the Egyptians confounded in their transcriptions. On the other hand, there were some Egyptian articulations preserved in the Coptic language which had no special representative in Greek or Latin, hence certain letters derived from the demotic were added to the Greek alphabet on its adoption by the Copts. (It must also be remarked that the Greek and Roman rule was an age of literary decay and ruin for classical Egyptian, in the depression of which little effort seems to have been made to represent accurately foreign sounds. The student must not be misled by the greater accuracy at this time in rendering the vowels, which was merely due to the decay of the system of

writing, by which the Egyptian vowels usually following certain consonant signs came to be disregarded.) Happily those Egyptian articulations which were unknown to the Greeks and Romans have at least analogues in the Semitic languages. Moreover, the many transcriptions of Semitic words (made while the Egyptian was in full vigour), joined to the traditions of the Coptic language (which has ceased for a hundred years to be a living speech), enable us to appreciate sufficiently those articulations unknown to the Greeks and Romans (and this indication may be followed in the case of the rest of the letters).

The words common to Egyptian and Semitic in the earliest known condition of the Egyptian language must be omitted from comparison. The more exact transcriptions of the scribes of the Ramessides (Dynasties XIX, XX) must take precedence of the looser ones of the earlier period of the Empire (Dynasty XVIII). Coptic, having long existed in a languishing state and under the influence of Arabic, whence the colouring of the latest dialect, the Bashmuic (Revillout ap. Rossi, *Gram. Copto. Ier.*, 30, n. 1), and certain peculiarities of the present pronunciation, is not an absolutely safe guide.

It might be thought that the study of the various modes in which words are written would furnish an exact table of homophones, and give us at once the list of distinct articulations, thus we might suppose that variants shewing two characters might enable us to assume their identity, as when in reading Greek we assume that θ is the same as θ. But in Egyptian, as in other written languages, there are certain licensed irregularities of orthography, and also oscillations between the different shades of sound in the same class of letters when used for the same word, a small number of variants between two letters therefore does not prove perfect homophony. Hence certain differences of opinion among Egyptologists, according to the weight, greater or less, which they give to this or that series of variants. Thus the number of letters under the "u" group differs with different scholars.

Without denying that there may have been some shades of sound in the different signs here called homophones, as in the sounds represented by the English "th," the chief guide should be the estimate the Copts made of the elements of their language, when they adopted the Greek alphabet, completing it for their purpose by adding six special letters taken from demotic writing.

The Egyptian Christians in adopting the Greek alphabet, which had vowels with fixed sounds made their writing undergo a radical change up to that time they had only vague vowels which were, as in the Semitic alphabets, simple aspirations, susceptible of being coloured by the sounds of different vowels (but this vague character must be limited by the vowels filling, as in Semitic, into three groups of sounds, the vagueness was therefore not unlimited. This characteristic of the old Egyptian influenced the Coptic, which presents in the vowels varieties of orthography of the same kind, these varieties, however, usually falling within the three ancient groups. It is only in the Coptic helping vowel that absolute vagueness is found, like that of the primitive "shva" of Hebrew.)

Following these indications we find 16 leading articulations in Egyptian, the shades of sound which may be most certainly distinguished would indicate an alphabet of 21 divisions. They are transcribed by letters taken, one, *x*, not to be confused with the Coptic *ϣ*, excepted, from the Latin alphabet, according to the principles of the Standard Alphabet of Lepsius, *Standard Alphabet*.

Σ, or under the ♂ in both dialects. The exceptions are as follows, in order of frequency—1, ♂ Sahidic, K Memphitic, 2, K Sibilic, 3, ♂ Memphitic, 3, K in both dialects, 4, Σ Sibilic, 5, Memphitic.

The graphic origin of the Copitic ♂ is doubtful. It is incorrect in our judgment to derive it, as hitherto, from the demotic ♂, coming from ♂, because of the suffix of the second person K has been rendered as f in the latest periods, almost contemporarily with the Copitic, by this demotic sign, consequently we ought to find it in Copitic under the form ♂ if this letter came from that sign, on the contrary, K is used for this person ♂ may have come from the demotic form of Δ, through the hieratic

DIACRITICS

The exact appreciation of the Egyptian dentals is hard. It seems certain that the three homophones ♂, ♂, ♂, answer to t, and that ♂, ♂, are represented in Copitic by the special dental then Σ. The sign ♂ seems to have the character of an intermediate shade of sound. In the Greek and Roman names, τ, θ, and δ are transmitted by all the signs without distinction (the Roman being first noticed through Greek forms). In the Semitic inscriptions H and B are indicated by ♂, ♂, and more rarely ♂, τ is indicated by ♂ with a marked precedence, I and S answer exclusively to ♂ and its homophones (including a later sign).

The Copitic adds to certain types, T, becoming ♂ Memphitic, and Σ, the trace of a third variety seems the period in the syllable T. We are thus led to distinguish three consonants t, t, and t'.

The three signs ♂, ♂, ♂, could be themselves as perfect homophones. The Greek and Roman names show them to be used for τ, θ, δ, but the hieroglyphs when they sought a more exact transcription of θ used the group ♂, θ (⊖ ⊖), which shows that originally the Egyptian t did not lend itself to the regular sound. The legend ΔB with Greek transcription, thus places ΔB in correspondence to an Egyptian word, written ♂ ⊖ ⊖. Taken, in which the first is a "navet locutions," of no value in pronunciation. In Semitic words ♂, ♂, served to transcribe regularly H and B, sometimes also τ, more rarely.

We observe no preference for transcriptions of t, this letter, which is not frequently found, corresponds even to ♂, t, in the name of Ptolemy. We may conclude that the special sound of the B had no existence in old Egyptian. The Copitic derived forms have but one type T for ♂ and its homophones, the Memphitic ascription changes it to ♂, following the rules of affinity we find some cases of derivation with Σ.

We pass at once to the third dental, t', of which the differential characteristic is more marked, perhaps the intermediate consonant may be more easily defined afterwards. The two signs, ♂, ♂, which we transcribe t', interchange in many Egyptian words, they are both varied with the very common syllable ♂, t' (which becomes an alphabetic sign though retaining its vocal, like an g), they act in exactly the same manner in the transcriptions and in the Copitic derived words. The hieroglyphs employed them, but very rarely, to transcribe the Greek τ and δ, and the Greeks felt some difficulty in transcribing this articulation, thus we find t' indicated by τ and δ, as by e, thus Σe n'ale is rendered by Sossos, and Hui and alef by Ametelos and Ainetelos.

In the canteche of Cambyses the Persian articulation Δ, J of Hawthorn, ♂, is found, it is transcribed by ♂, t, but not constantly, variants show a simple t. Therefore this was not a perfect identity between the Egyptian t' and the Persian Δ. The Hebrews had two substitutes more or less standing off into cerebral, t and y, they are constantly transcribed by ♂, t, and its homophones, and not by t, but we do not remark a preference in favor of this on that sign in either of the two Semitic letters, and this confusion shows that there was but an approximative correspondence.

The Copitic derived forms from the ancient t' are divided according to two rules—they are written either (1) with Σ in the two dialects, or (2) with Σ Sahidic, corresponding to ♂ Memphitic—the dialect of Upper Egypt showing a higher extension. The exceptions show us—1, T Sahidic, ♂ Memphitic, 2, ♂ Sahidic, Σ Memphitic, 3, ♂, t, the syllable, e, r, all the letters which show a kind of affinity with this dental, of which we cannot now fix the pronunciation beyond saying that it approached the sibilants and the cerebrals. The Copitic preserved it in Σ, which comes from the hieroglyph ♂, though

the hieratic ♂, ♂, becoming in demotic ♂ this was developed and made regular by the Copits. The Copitic must now give precise information as to the pronunciation of Σ, in the last century, an attempt was made to indicate it by J. Dr. Bueghz proposes for the ancient letter τ, and Dr. Bueghz, it seems to us that the conventional t' is more suitable to the Egyptian variants of the articulation, which constantly make it approach t.

In the eyes of the ancient Egyptians the letter ♂, t, was a new nothingness of t', it could even be considered as a homophone if we had only the evidence of the variants, for variants between ♂ and ♂ are numerous, and found in the earliest texts. The variants between ♂ and ♂, ♂, ♂, are not enough, and being above all to the late periods.

But the Memphitic transcriptions indicate the principle of a distinction. From among them it is noticed that ♂ is connected with t with a very marked preference. From the Nineteenth Dynasty, when the system of these transcriptions appears to have been made regular, on account of the many relations established with the neighbouring languages by consequence of commerce (into Egypt), this preference became so constant that it led Dr. Bueghz to transcribe ♂ by a d. The exceptions to this rule place the ♂ beside B and T, which in the contrary.

In Copitic the derivatives of ♂, t, do not act like those of ancient words usually written with t. We find the derivatives of ♂ regularly under the dentals T, ♂, T, sometimes also under Σ, but in very small number. The verb t, "to give," ordinarily written Δ, becomes in Copitic T. This sign, which the Coptic Copits pronounced d, is considered a simple ligature for T and I. But Dr. Bueghz has remarked that T resembles the demotic ♂, corresponding to Δ, "to give," too much for the homonym to be due to chance, there was here a recollection of the syllable and the phonetic, and the Copits took the T from demotic with their other special letters.

Evidently these two groups of documents may induce us to mark the ♂ as a special letter, but this letter could not be a d. In fact, the Copits excluded Δ from their native words, and the hieroglyphs indicated that the ♂ was not a true d when they would transcribe more exactly the Latin d, which they found in foreign names, they employed a double letter, Δ. We notice this in variants of the onomastic of Darius in the Ptolemaic and in the Latin d in the surname ♂, n' (⊖) (⊖), for Darius, inserted in the canteche of Tyran. This wholly artificial scribble aims to approximate a peculiarity of the Egyptian dentals, that after the usual pronunciation softened in the direction of d. This explains many Greek transcriptions which show the d, as *Agathos*, which represents ΔB as *not*. The d being out of the question we select t' as near the point of view of the hieroglyphic variants where ♂ represents t'.

LAGINES

The three signs ♂, ♂, and ♂ exactly answer to m, the transcriptions are uniform, always a Greek and a Semitic.

The Copitic derived forms are almost always Δ, some even appear presenting Δ, B, T. One must be very careful in Copitic not to confound a radical Δ with that which comes from Δ by assimilation before a labial, as in the Sibilic particle Δ, coming from ♂, "m," before the article T. It is also to be remarked

1. Of the Gnostic word Sabait, which does not differ from the other but by the absence of the flexion x, and retains the t.

minative of sound from the ordinary use as determinative of sense)

Syllables are divided into two classes—1, an attention and one or more vowels, 2, two virtual ones (usually, with a medial helping vowel unexpressed. All air, no doubt, monosyllables, although a syllable like *sea* has the appearance of a dissyllable, *heio*, either the first *h* has no force, or the two indicate a long vowel.)

The first class of syllables, an attention and a vague vowel is scarcely distinguishable from the letters of the alphabet. The distinction is thus determined, 1, the simple letters were used as phonetic complements, 2, the syllables do not seem to have been used quite indifferently for all kinds of vowels. We frequently find allusions, relations direct or remote, which have originally induced their choice for the purpose of writing this or that radical. (Thus is strictly analogous to the principle of the syllabary of Assyrian Babyloian in its Akkadian and Sinitic developments, though in its application that principle led to wide polyphony, in consequence of an ideograph taking different sounds, according to the cognate senses in which it was used.)

It is also possible that the syllables were sometimes employed to give an idea of the sound of the vowels. But if they had this use primitively, they did not retain it, for we cannot establish this property in a constant manner in the hieroglyphic transcriptions of Greek or Sinitic words. (It is indeed the converse use of the vowel most affected by a consonant or of the syllable with its vowel which is not almost constant in the readings of Sinitic transcriptions.)

There were also some signs corresponding to three articulations which could be used in syllables. Here the cases of homophony are much more rare, we have to do with different acceptations rather than different radicals, but the ideal bond between them, different acceptations may escape us now. (These are still monosyllables.)

POLYPHONY

There are characters which had various pronunciations. There are three kinds of polyphonies.

1 A sign can answer to various words which belong to the same class of ideas, thus, the cat's ear, , answers to the words , *met'ar*, , *ankh*, and , *ar*, which seem to have all signified the ear or some special part of this organ. The words , *sem*, and , *setem*, "to hear," are two new values, on the same principle. One might add to this first class the very new values produced by variants of pronunciation or writing for the same word, such as *ta*, *ta*, *tu*, *ut*, *ant*, *ant*, *antu* for , and the forms more or less developed of a single root, but these are rather extensions of a word than true instances of polyphony.

2 The same sign might have been chosen as symbol of a certain number of ideas without any true bond between them, at least to our view. Thus , answers to the phonetic , *nen*, "largeness," to , *ab*, "offering," and , *hent*, "regent" (*sem*).

3 A sign may have become syllabic and be used for several purely phonetic values taken from the words in which it figures, on the two principles explained. Thus in the syllabary, the sign , which symbolizes the idea "gift," answers to two roots, *tu* and *mā*, these give in their turn to , *tu*, and , *mā*, even in words where the idea of gift no longer exists.

Such is the series of facts which has produced Egyptian polyphony. The number of figures suitable to design and with which one could reasonably charge the memory being limited, we should expect to find polyphony more or less developed in every system of writing originally ideographic. The syllabic polyphony of Assyrian seems to have been produced by wholly analogous circumstances, though the change from the original language habitually veils the connection of values.

Polyphony is a source of great difficulty, and science has still much to do to fix the different phonetic values of the polyphones. Often our decision is made on the evidence of phonetic complements, and in hieratic it is seldom that this aid is wholly omitted.

Thus  is easily recognized as *mā*. But our ignorance is not always thus aided, and the choice of the suitable word sometimes can only be indicated by a profound study of analogous texts.

The following list gives an abridgment of De Rouge's list of syllables, and contains the most common signs, the important polyphones being indicated by asterisks, and their principal varieties of sound being given in the fourth column. The method is varied from that of the *Chesterfield*.

TABLE OF THE MOST COMMON SYLLABIC SIGNS

SIGN	SOUND	SIGN	SOUND
1 	<i>at</i>	κ 1* 	<i>lēs</i> <i>ka</i>
2 	<i>āa</i>	κ 1* 	<i>la</i> <i>lēs</i>

DETERMINATIVES

Champollion described as determinatives certain ideographic signs which were placed after words phonetically expressed. The use of each of these signs is more or less extended. The greater part are used for one radical, or at least for one and the same idea. For such determinatives the proper place is the dictionary. But there is a class of determinatives placed after different words, often many in number, and therefore called generic determinatives. The determinative is attached to the radical, and has nothing to do with the grammatical use of a word as noun or verb. (M. de Rougé gives a list of above a hundred as necessary for the student of Egyptian grammar, leaving out those of more restricted use.) Science has not yet wholly accomplished its task in this section. (Necessarily the exact definition of the range of a determinative requires a careful induction from its use.)

(The table which follows is but slightly abridged from M. de Rougé's, after comparison with Dr. Birch's in his *Glossaire Hieroglyphique*, where a somewhat fuller but less logical list is given, apparently founded on that of the French savant. The reason for here giving a larger proportion of determinative than of syllabic signs is that the sense of the determinatives when logically arranged, as by M. de Rougé, present a key to the whole construction of the Egyptian system of ideographic signs, and afford us a remarkable insight into the genius of the language.)

TABLE OF GENERIC DETERMINATIVE SIGNS

SYMBOL	VARIANT	REPRESENTING	DETERMINING IDEAS
1		ceiling	sky, ceiling, to raise, superiority
2		ceiling with stars	night, obscurity
3		sun	sun, light, divisions of time
4		star	stars, constellations, gods, divisions of time
5		hilly country	country, mountains, nations
6		oval	islands, cases, maritime countries
7		?	cities, villages
8		country divided	nomes, districts, fields
9		river	territories and their portions, dikes, mud
10		fish	water, liquid, seas, rivers, to wash, freshness, level
11		flaming censer	boat, boat, seal
12		man (squatting)	proper names, pronouns and participles
13		man sitting	more general, often used in Egyptian period for the more special determinatives following the next
14		man and woman	humanity, its divisions, classes, participles pl
15		man with long beard	gods, august persons, kings
16		portraged on the oval holding whip	ancients, princes, kings
17		similar, kneeling	similar, defunct persons, maids
18		man holding, his hand to his mouth	actions of the month, eating, speech, thought
19		man holding hands	adoration, invocation, prayer
20		man bound	enemies, prisoners, power
21		man stamping and striking himself	impunity, porosity, clowns
22		man, a man	enemies, to strike, death, massacre
23		man, his right hand raised	exclamation, invocation
24		man, a man raised	height, grandeur, joy
25		man, with staff	chief, great, distinguished

TABLE of GENERAL DETERMINATIVES—SIGNS—continued				TABLE of GENERAL DETERMINATIVES—SIGNS—continued			
SIGN	VARIANTS	REPRESENTING	DETERMINING IDEAS	SIGN	VARIANTS	REPRESENTING	DETERMINING IDEAS
25		armed, holding club (or oval)	old age, to end	48		cult's face, head	nose, nostrils, lungs, to swallow, breathe, sleep, pleasure, to separate, shut up, revolt
26		child, hand to mouth	infancy, youth, to suckle, education, receiving	49		head of ox on support (?)	throat, gullet, lungs, &c. to eat, breathe
27		mummy	embalming, mummies, images, to put, forms	50		piece of skin	quadrupeds, objects in leather
28		familiar couch, without or with mummy	mummies, death, disease, embalming, to hold down, rest	51		bone with flesh?	members in general
29		woman squatting	women, goddesses, female deities, and parts of the body	52		Nile duck	birds, flying insects
30		varied by many attributes		53		wing	smallness, vile, wicked
31		head of man in profile	head, superiority	54		wing	wings, without, to fly, rise
32		eye	him, black, columns in general, grief, tears	55		egg	eggs, oviparous animals, race, descent, lineage
33		human eye, iris, pupil	to see, to write, to know, curvy	56		crocodile	crocodiles of different kinds, divinity, conchoid, therefore, to conceal oneself, to spy, destruction
34		fish	to swim, to go	57		kind of fish	fishes, fishing, impurity, prohibition
35		snake, old's head	to breathe, smell, joy, pleasure	58		serpent	repulse, worms, several accounts, name of certain gem
36		tooth	biting, speech, hard objects, stones, &c., rupture, directions, everything relating to the mouth and solids	59		kind of tree	trees of all kinds
37		hand holding small club	all actions implying the use of any force	60		dry branch?	different kinds of wood, objects made of wood
38		hand, the palm below, foot of bird lying down	arms, shoulders, sides, directions, gentle actions, rest, gentleness, account, songs	61		palm shoot?	new, young, time, youth, to renew
39		hand holding two arms, arms and legs, arms	to embrace, unite, to square, on horse, to embrace, to embrace, to embrace	62		branch of flowers	plants, flowers, objects composed of plants
40		extended arms	negation, prohibition, adverbs	63		grains	corals of different kinds, to labor, to harvest, measures
41		phallus	male, generation, pollution, to pour out, fruits of generation, in front, veins	64		basket pouring out grain, vase full of grain	corals of different kinds; harvest, tribute, to measure, basket
42		bent leg	leg, foot, knee, &c., walk, diminution and enlargement, measures of length	65		ground plan of room	abodes, places in general
43		hand holding knife	to carry off, leap over, surprise, diminish, annihilate, violate	66		wall	walls, satisfactions, enclosure
44		legs walking	locomotion	67		the same, falling	to stagger, crumble, destroy
45		the same reversed	return, send back, repel	68		steps	stair, to mount, to approach, foot of a monument
46		hand holding part	behind, to follow, to revolt, refuse, force, violence	69		fortified enclosure	names of fortified cities (written within the determinative)
47		Typhonian animal	revolt, violence, disorder, tempests, storms	70		basin	writes, rivers, seas, canals, beams, to fill, gate, cultivate

it forms the group  1, not only for the substantive *har*, ka, "face," but also for the particle *har*, "upon," &c. In hieratic, l is attached to many characters, probably to distinguish them from very similar ones, thus  for

 is clearly distinguished from  for . It is thus used as a diacritical sign, though very variably. At the end of words we find, above all in late times, the explicative 

EXPLECTIVE VOWELS AND COMPLEMENTS OF SIMPLE LETTERS

Although the vowels were often omitted, sometimes they are added in a wholly explicative manner, which their vagueness can only aid us to understand. This is easily proved from certain words transcribed, such as *bar*, the Egyptian                          

It will be remarked that all the phonetic forms, but two are written with alphabetic signs, that the introduction of ideographs, either as determinatives or independent symbols, gives the common first sign an additional meaning in writing but not in sound, and further confuses this meaning and the true meaning of the second personal singular when represented by the same symbol only. The principle of writing an ideograph to determine the use of the phonetic, phonetically expressed or only represented by this symbol, is called *lithos* in the first personal singular in the table above, these being special signs for *god*, &c.

In the use of the vowels and the phonetic of most common are alphabetic signs as employed with ideographic signs for the phonetic when the necessity occurs. Syllabic signs are used for some of the less common phonetic, and ideographs for substantives employed as phonetic. The full form of phonetic is produced by alphabetic signs, the same is usually the case with the compounds that introduce new elements.

The verbal root, identical with that of the noun, is expressed in every mode, in which hieroglyphics can be used. It is, however, identical with the derivative form, the inflexion, and the substantive verb, which in its various expressions is really an inflexional word employed in form, but not in sense. The derivative forms are produced by prefixes which are always alphabetic or by repetition of the radical (reduplication, sometimes with a *wa* inserted). The inflexions are formed by the phonetic inflexion for the persons and other inflexions and suffixes, these affixes being almost always placed before the phonetic one for the mood and tense, hence again the expression in alphabetic with the exceptions afforded by the phonetic inflexions as already shown. The forms of the substantive verb are phonetic, either alphabetic, or

identity of some forms of this verb and of other parts of speech. Thus *na* is the same in form as the definite article, and *na* with the affixes as the possessive article, and *na* is the demonstrative article. These identical forms are here cited as evidence of the result of the use of alphabetic writing.

The radical particles show the same phenomena. The positions are expressed phonetically, the majority, including nearly all the most common, alphabetically. The simple inflexion, including the negatives, are written phonetically, with perhaps about an equal use of alphabetic and syllabic forms. The few inflexions are written alphabetically in consequence of this mode of writing, particles of different sense are sometimes identical in form. Thus *na* is both "in" and "not" but most apparent instances of this kind are due to the use of a particle as both preposition and conjunction or adverb.

The bearing of these results on the problems of the formation of the Egyptian hieroglyphic writing and the growth and origin of the language is significant.

The earliest Egyptian writings, which are hieroglyphic, show a predominant use of ideographic signs. The phonetic signs gradually grow in importance with the full development of the character and language. We are thus led to ask whether there was a period in Egyptian writing when it was wholly ideographic, the supposed stage of all such systems, when the figure of each object conveyed its name or names and nothing more.

A stage of pure picture writing would express a language in the condition which is supposed to have been the earliest in the case of all monoglossic languages, the condition before grammar. It is peculiarly clear that a condition in the linguistic phenomena of Egyptian seems to point for its simple necessity a picture stage as a sufficient, and the phonetic signs written for grammatical necessities would be introduced when a higher condition was reached.

It may be further enquired whether the growth of Egyptian was wholly introduced or whether it was introduced from without, in other words, whether there is any reason to assign the roots which serve the purposes of grammar, and even the verbal roots to more than one source? On the basis of the inquiry by which this question might be answered, it is in the undoubted identity of the personal pronouns in Egyptian and Semitic. The inquiry is beyond the scope and limits of this article. It requires an exhaustive comparison of the Egyptian vocabulary, including the structural words, and of the system of grammar, with the Semitic and with the families of languages which group together and etymological considerations would lead us to include in the category of possible cognates to the Egyptian. The leading results of a limited examination may, however, be stated. In the verbal roots a certain small number occur, apparently common to Egyptian and Semitic. Of these roots a good proportion are proper to civilization, and thus belong to a stage above that of barbarism. In the personal roots the personal pronouns are undoubtedly Semitic, whereas the articles seem to be identical in source with a non-Semitic form of the substantive verb. The roots of particles fall into two classes, those which are purely metaphysical, partially including Semitic equivalents, though in the case of passive, uninflected forms the comparison is hazardous, and such as it is, it becomes precarious by the division of substantives into a typical sense.

It would thus appear that the Egyptian language was originally a monoglossic language without inflexion and written by ideographic signs, that the first stage towards inflexion was the use of substantives in typical cases for prepositions and adverbs, the primitive ideographic signs being still sufficient for the purposes of writing, and that the second stage was attained by borrowing from Semitic, in as far as was necessary, grammatical forms and particles, with perhaps some verbal roots needed in a civilized condition, and that at this time phonetic signs became absolutely necessary. The importance of the phonetic signs for expressing grammatical forms could then be their prevalence in the whole category, except which the inflexion signs was deemed in the typical, is in our own use of the word "head" in each proposition, and the base as "the base" in the case of the administration, &c. This view is put forward as a mere hypothesis, to be sustained or refuted by the study which the subject deserves. The important use of the question is great as its solution will mainly tend to determine whether the Egyptian belongs to an early stage of Semitic, as has been conjectured on very insufficient grounds. In the present remarks it is assumed that such a view may at present be set aside, otherwise we could not speak of borrowing from Semitic.

THE SUPPOSED DERIVATION OF THE PHOENICIAN FROM THE EGYPTIAN ALPHABET

M de Rougé endeavored to show that the Phoenician alphabet was derived from the Egyptian in its hieratic form. The hypothesis has been accepted by M. François Lenormant in his *Essai sur la Propagation de l'Alphabet Phénicien*, 2d ed., 1874, in which the facts are presented in a comparative table of hieratic and archaic Phoenician letters. The method leaves nothing to be desired. The conclusion is, however, scarcely established. It must be remembered that the Egyptian alphabet presents one or more alternative forms of more than half its letters. Most of these correspond to a single Phoenician letter. Thus there is in half the Phoenician alphabet a choice between two or more hieratic forms. This diminishes the effect of the comparison. Again the hieratic forms vary, like all cursive forms of writing, with the hand of each scribe. Consequently the writer who desires to establish their identity with Phoenician can scarcely avoid strengthening the evidence. Any one who will compare M. Lenormant's plate with M. de Rougé's hieratic alphabets in the *Cat. égyptienne*, Pl. I seq., will see that the signs chosen for comparison by M. Lenormant do not agree throughout with any of the three types given without that object by M. de Rougé. It may be remarked in illustration that if we endeavored to connect the demotic in its latest form

with the Arabic Kofee in its earliest, which is of course absurd, it would be possible, by selecting the demotic variety nearest in form to the typical Kofee of cuneiform inscriptions, to show a very good apparent agreement of many letters. Any one may try the experiment with the Kofee alphabet in Soret's *Nomenclature Minuscule*, Pl. I. and M. de Rougé's demotic in the *Chronologie* (10), taking care to use only one type where it was repeated by the Arabs for other letters, and in the case of their alphabet to compare only the isolated or final forms. The result would show the great caution needed in the inquiry.

There are two objections to the proposed derivation of the Phœnician alphabet which must have great weight against any but the strongest evidence of resemblance. The Egyptian letters represent objects, similarly the names of which begin with these letters, similarly the Phœnician letters had names indicating an origin from a hieroglyphic system on the same principle of acrophony. It would be supposed if the Phœnician letters were derived from the Egyptian ones that their names would describe the original signs. This, however, is not the case in a single instance. Aleph signifies an ox and not an eagle, Beth a house and not a bird, Gimel a camel and not a basket, and so, as far as we know, to the end. It is difficult to imagine the complete loss of the original form, and the naming of letters from a supposed resemblance to another form, which form can scarcely be traced in the most ancient Phœnician. Yet, if the derivation from hieratic be true, we are led to this chaotic form on account of its apparent similarity to the hieratic, and any deviation to explain the Semitic names of the letters would weaken, it not destroy, the foundation of the theory.

Again, it is very noteworthy that the oldest monuments of the Phœnician alphabet are to be found not in Egypt but in Palestine and Assyria. These are the Stela of Meshi, king of Moub, and the inscriptions on the Nimrod bronze lion-eights. These weights take us a step farther in the argument, for they show us on official documents of a palace of Assyrian king the use of this alphabet, side by side with the Assyrian character, as a kind of demotic or perhaps commercial writing, of necessity well-known in Assyria itself. Of course it is not to be supposed that the languages expressed were the same, but they were so closely allied that their joint use in Assyria was natural, and particularly to a nation accustomed to the Tammul Akkadian. This appearance of the Phœnician alphabet in Assyria would suggest that it had its origin rather from Assyrian than Egyptian writing. Is there, however, any evidence that any such alphabet was derived from cuneiform?

Among the systems of writing which present a sufficient similarity to the Phœnician, and its descendant the Greek, to justify one conjecturing their common derivation, though not necessarily their later connexion, is the Cyprian. This is radically different from the Phœnician in being syllabic, and thus having a much larger list of characters, but the formal resemblances suggest the same source. In the case of the Cyprian, Dr Deecke has endeavoured to show the source to be the Assyrian cuneiform in its later form. His arguments are very strong, here it is only necessary to mention the syllabic character of the Cyprian, the agreement in form of many signs, without the readjustment of their elements suggested as theoretically possible by the Median and Armenian variants, and the striking fact that the Cyprian is found in two inscriptions written in cuneiform, each stroke having the Assyrian typical shape (Deecke, *Der Ursprung der Kyprischen Sylbenschrift*, Strasburg, 1877).

This probable solution of the Cyprian problem suggested to Dr Deecke the comparison of the Phœnician alphabet with Mesopotamian cuneiform. The result, published in the *Zeitschrift der Deutschen Morgenländischen Gesellschaft* (xxvi 102 seqq.), is well worthy the attention of scholars. The inquiry was founded on the comparison of forms and sounds in cuneiform. The forms were much less numerous than the extent of the list of signs would lead us to expect, for the great majority of these signs are far too complex to have been the prototypes of such simple signs as the Phœnician letters. The sounds on the same side present no little difficulty, as the adoption by the Babylonians and Assyrians of the Akkadian system of writing produces a confusion of kindred sounds and excludes some proper to the Semite alphabets. A further difficulty arises from the polyphony of the Assyrio-Babylonian cuneiform signs, whether ideographic or syllabic, which gives a variety of sounds to the same group and thus greatly diminishes the degree of probability in an agreement. These signs are all conventional transcriptions of original hieroglyphics. These hieroglyphics can sometimes be traced in the same hieratic forms, and even occasionally in the regular cuneiform types. When we know the original form we can sometimes select the radical sound, but when we find more than one cognate sense with a different sound, the selection becomes difficult, if not impossible. Supposing such a sign to be represented by the English *hano* 1, standing for "one" and "first," the discovery of the radical sound would be apparently hopeless. It would be obviously so if the sign also stood for "beginning" and "union." The result seems satisfactory to the extent of about one third of the Phœnician alphabet, signs like the Phœnician having like sounds. This result would have little force did it not seem to be supported by the meaning of some of the signs as compared with the names of the Hebrew letters, of which we know the meaning, seventeen in number. But the difficulty in discovering the original radical sound and sense in cuneiform shakes this conclusion. Consequently the agreements which might be accepted were no certain of the original Assyrian sound and sense seem to have much weight. There are also some probable agreements which, of course, have still less strength. It is, however, to be noted that the syllable *had*, &c., taken as the origin of *heth*, and *ty*, as that of *teth*, have forms in the hieratic cuneiform agreeable to the meaning of the words from which these syllables are supposed to be abbreviated, *hattu*, a "graven," and *dhbu*, a "writing-table." This explanation of the signs *heth* and *teth*, consecutive, be it remembered, and without certain underlings, in the Hebrew alphabet, is very remarkable as a confirmation of the theory. For the present it is no more than a theory, but perhaps it is as probable as the derivation of the Phœnician alphabet from Egyptian hieroglyphics, through the hieratic types.

It is of course possible that the old Semitic alphabet had an origin independent of Egyptian hieroglyphics or the conventional hieratic forms of Assyrio-Babylonian cuneiform. The discovery of a new hieroglyphic character in the Hittite inscriptions, continuing, in a list of greater extent, certain of the forms indicated by the names of the Hebrew letters, is a new factor in the problem, and must be defined before its true value can be ascertained. All that can be said at present is, that the Hittite characters were the product of an Egyptian origin. Considering the geographical position of this mode of writing, its *prima facie* evidence is in favour of M. de Rougé's derivation of the Phœnician alphabet from Egyptian.

among which may be mentioned Anundel House, in which Trecen died in 1636, and Landedale House, once the residence of Lord Landedale, one of the "Chival" of Charles II., now used as the convalescent home of St. Bartholomew's hospital. The principal buildings are the church of St. Michael, erected in 1832, in the Perpendicular style, containing a monument to Coleridge, who had his residence in Highbury for nineteen years, the new building erected in 1868 for the grammar school founded by Chief Justice Chalmers in the time of Elizabeth, the Roman Catholic monastery called St. Joseph's Retreat, a splendid and spacious structure in the Italian style, recently erected, the London diocesan penitentiary, the infirmary, the small-pox and vaccination hospital, the Alexandria orphanage, and the Whitlington almshouse. Near the foot of the hill is the Whitlington stone, erected in 1821 in place of the old one, which was removed in 1795. In 1809 a scheme was projected to avoid the steep ascent at Highbury by means of an arched tunnel, but after the work had proceeded about 130 yards the whole fell in on 13th April 1812. A road was, however, formed in the line of the intended tunnel, passing under an arch over which the ancient road, Hoinsey Lane, is continued. The North London cemetery, in the neighborhood, contains the graves and monuments of a great number of celebrities. Highbury is supposed by some to have received its name from the gate erected by the bishop of London for the purpose of receiving toll from the passengers by the road which at this point entered its park, but it is possible that gate is now used according to its old significance, and that the name simply means high road. The road was constructed in the 11th century, and the toll-house was built on the site of an ancient homitige. In the time of stage coaches a custom was introduced of making ignorant persons believe that they required to be sworn and admitted to the freedom of the Highbury before being allowed to pass the gate, the fine of admission being a bottle of wine, which was discussed at the conclusion of the ceremony. The population of the parish in 1871 was 6437, and of the township 5331.

HIGH PLACE is the rendering invariably given in the authorized English version of the Old Testament Scriptures to a Hebrew word *gib* of uncertain derivation but with much plausibility connected by Gesenius with the Indo-Germanic root which appears in the Persian *dam* (roof, summit), and in the Greek *βουνός* (compare *βύνα*, Doric *βύνα*). By the LXX the word is sometimes left untouched (*gib* in 1 Sam. ix 13 and elsewhere), the prevalent rendering of the plural, when a translation is hazarded at all, is in the Targum *gib*, in the historical books *gib* (*gib*, *gib*, *gib*), and in the prophetic writings *gib*. The Vulgate invariably gives either *ecceles* or *gib*. The habit so widely diffused among primitive peoples of selecting the tops of mountains, or at least elevated sites, as suitable from their comparative isolation from the world and their supposed nearness to the sky for the erection of altars and sacred pillars, is so obviously natural as to require no explanation. Along with that of worshipping under trees or groves (see GROVE), it was fully participated in by the Israelites from an early period, and continued to assert itself down to a very late date, as is abundantly shown by the frequency with which *bamah* and other words (*har*, *gib*, *gib*, *ramah*) signifying height occur in connection with their public and private worship, whether Jehovahistic or idolatrous. Thus one of our earliest notices with regard to Abraham after his departure from Haran is that, after setting up a sanctuary at Sichem at the oak of Moreh, he "removed unto a mountain on the east of Bethel, and there he built an altar unto the Lord" (Gen. xii 8). It was on a mountain (*Ebal*) that the first altar to Jehovah was raised

by Joshua after the conquest of Canaan had begun (Josh. vii 30, cf. Dent. xxvii 4, 5), and many other "high places," some of them (*eg*, Beth-Shean, or I. Ure, and Ashteroth Karnaam) apparently taken over directly from the Canaanites, speedily obtained recognition as sanctuaries. A few of these, such as Shiloh, early became important pilgrimage centres, but this was not regarded as inconsistent with the right of each town or village community to have its own high place, or with the view that Palestine as a whole was the "house" or peculiar territory of God, and that it was therefore lawful on suitable occasions to erect new and extensive altars or high places within its limits. For example, we find in 1 Sam. x, xi repeated references made to the *bamah* of Samuel's native village as if it were a thing of course, from 2 Sam. xii 32 (Heb.) we gather that even in David's time the top of Mount Olivet was a place "where God was wont to be worshipped," while at a later period we read of Elijah repairing the altar on Mount Carmel that had been broken down, and complaining of the violation of God's covenant of which those persons had been guilty who had thrown down the altars and slain the prophets (1 Kings xvii 30, xiv 10, 14). And we read of new altars, generally on high places, being set up by Gideon (Judg. vi 26, 27), by Manoah (Judg. xiii 19, 20), and repeatedly by Sam. (1 Sam. xii 35). The comparatively late author of the books of Kings, expressly states, on the one hand, that before the days of Solomon the people "sacrificed in high places because there was no house built unto the name of the Lord" (1 Kings vi 2), and, on the other hand, that after that king the high places were removed neither by Aza (1 Kings xiv 15), nor by Jehoshaphat (xv 41), Joash (2 Kings vi 3), Amaziah (xiv 4), Uzziah (vi 4), or Jotham (xv 35). The still later author of the books of Chronicles, indeed, states of Aza (2 Chr. vi 6) and Jehoshaphat (xv 6) that they did take away the high places "out of all the cities of Judah." This apparent contradiction can best be explained if we assume that the chronicler is alluding only to those high places where heathen deities were worshipped or idolatrous practices allowed, while the earlier author had in view the Jehovahistic high places which, during many of the earlier reigns at least, were not discountenanced either in the north or in the southern kingdom. In reading such a passage as Amos vii 9, it would be a mistake to interpret it as meaning that the multiplicity of *bamoth* was regarded as wrong in itself, the prophet's zeal is directed not against the places but against the cultus and the false value that was attached to it. Hezekiah is the first monarch of whom in the earlier record we read that with some risk to his popularity he removed the high places and altars of Jehovah, and "said to Judah and Jerusalem, ye shall worship before this altar in Jerusalem" (2 Kings xviii 4 compared with xvii 25). But it was not until the reign of Josiah that the high places were finally repressed, not on the ground of direct prophetic revelation, but on that of a strict written law. Even then, however, a distinction was made between the "high places" of the southern kingdom, sacred to Jehovah, and those of the north, dedicated to a mixed worship, the priests of the former were brought to Jerusalem, and, though not allowed to officiate at the altar there, were permitted to share the priests' portion along with their brethren, while those of the latter were put to death (2 Kings xxiii 8, 20). As for the altars built upon the high places, their construction appears to have been regulated by the law provided for the case in Ex. xx 24, 25, very often *magpah* or pillars were erected beside them (see Ex. xiv 4, Josh. xxiv 26, cf. Isa. xix 19, Hosea in 4), and sometimes they were enclosed in "houses" or "temples" (1 Kings xii 31, xii 32, Amos vii 13). For the bearing of the facts contained

in this article on the entrance of the Pentateuch and of its legislation, see PENTATEUCH.

HIGHWAYS. A highway is a public road over which all persons have full right of way—walking, riding, or driving. See ROADS. Such roads in England to the most part either are of immemorial antiquity or have been created under the authority of an Act of Parliament. But a private owner may create a highway at common law by dedicating the soil to the use of the public for that purpose, and, apart from any special dedication, the using of a road for a number of years, without interruption, will support the presumption that the soil has been so dedicated, and the road will be to all intents and purposes a public highway. At common law the parish is required to maintain all highways within its bounds, but by special custom the obligation may attach to a particular township or district, and in certain cases the owner of land is bound by the conditions of his holding to keep a highway in repair. Breach of the obligation is treated as a criminal offence, and is prosecuted by indictment. Bridges, on the other hand, and so much of the highway as is immediately connected with them, are as a general rule a charge on the county, and by 22 Henry VIII. c. 5 the obligation of the county is extended to 300 yards of the highway on either side of the bridge. A bridge, like a highway, may be a burden on neighbouring land, *ratione tenetur*. Private owners, so benefited, may sometimes claim a special toll from passengers, called a "toll traverse."

Extensive changes in the law of highways have been made by the recent Highway Acts, viz., The Highway Act, 1833 (5 and 6 Will. IV. c. 50), and the amending Acts of 1862 and 1864. It is no longer possible for a private owner, by dedicating a highway to the public, to make the charge of maintaining it a burden on the parish in all cases. To create a new highway of this character he must give three months' notice of his intentions to the parish surveyor, and a meeting of vestry must then be called to consider whether the proposed highway is worth the expense of maintenance. Should the vestry decide against it, the charge of maintenance will not fall on the parish, unless the justices of the peace at the next highway sessions decide otherwise.

The leading principle of the Highway Act, 1835, is to place the highways under the direction of parish surveyors, and to provide for the necessary expenses by a rate levied on the occupiers of land. Two or more parishes may unite to form a district under a district surveyor, and large parishes may appoint more than one surveyor. It is the duty of the surveyor to keep the highways in repair, and if a highway is out of repair, the surveyor may be summoned before justices and convicted in a penalty not exceeding £5, and ordered to complete the repairs within a limited time. The surveyor is likewise specially charged with the removal of nuisances on the highway, or any obstruction or injury rendering it less commodious to the public. A highway nuisance may be abated by any person, and may be made the subject of indictment at common law. The Act contains provisions simplifying the process by which a highway may be widened, enlarged, diverted, or stopped. The amending Acts, while not interfering with the operation of the principal Act, authorize the creation of highway districts on a larger scale. The justices of a county may convert it or any portion of it into a highway district to be governed by a highway board, the powers and responsibilities of which will be the same as those of the parish surveyor under the former Act. The board consists of representatives of the various parishes, called "way wardens," together with the justices for the county residing within the district. Salaries and similar expenses incurred

by the board are charged on a district fund to which the several parishes contribute, but each parish remains separately responsible for the expenses of maintaining its own highways.

The Highway Act of 1835 specifies as offences for which the driver of a carriage on the public highway may be punished by a fine, in addition to any civil action that may be brought against him,—riding upon the cart, or upon any horse drawing it, and not having some other person to guide it, unless there be some person driving it, negligence causing damage to person or goods being conveyed on the highway, quitting his cart, or leaving control of the horses, or leaving the cart so as to be an obstruction on the highway, not having the owner's name painted up, refusing to give the same, and not keeping on the left or near side of the road, when meeting any other carriage or horse. This rule does not apply in the case of a carriage meeting a foot-passenger, but a driver is bound to use due care to avoid driving against any person crossing the highway on foot. At the same time a passenger crossing the highway is also bound to use due care in avoiding vehicles, and the mere fact of a driver being on the wrong side of the road would not be evidence of negligence in such a case. When there is a public crossing in a street, the driver is bound to use special care, and the expression has been used that a crossing is the special property of the foot passengers.

The "rule of the road" given above is peculiar to the United Kingdom. Cooley's treatise on the *American Law of Torts* states that "the custom of the country, in some States enacted into statute law, requires that when teams approach and are about to pass on the highway, each shall keep to the right of the centre of the travelled portion of the road." The same appears to be the general rule on the continent of Europe.

The excessive use of the highway by acts which in moderation are lawful becomes a nuisance if it interferes with the public enjoyment of the roadway. Thus when a carrier, having warehouses on a public street, occupied one side of the street in loading and unloading his waggons several hours at a time, so that foot passengers were incommoded and no carriage could pass on that side, although there was room for two carriages on the opposite side, this was held to be a nuisance, and Lord Ellenborough held it to be a nuisance for stage coaches to stop in the street for three quarters of an hour taking up and setting down passengers, for the "king's highway was not to be used as a stable-yard." In the same way, at common law a tiamway laid along a highway is a public nuisance, although it may be shown to be a common convenience. The construction of tramways is now authorized by 35 and 36 Vict. c. 78.

The Acts 24 and 25 Vict. c. 76, and 28 and 29 Vict. c. 83, regulate the use of locomotives on turnpikes and other roads. No engine, so constructed as to be a public or private nuisance, is protected by these Acts. When horses had been frightened by a traction engine, and the jury found that it was likely to frighten horses and that the defendant knew it, he was held liable in damages.

Turnpike Acts.—Many of the more important highways are placed under the management of boards of commissioners or trustees. The number of local and general turnpike acts is very great. No fewer than thirty-three general acts are mentioned in the index to the statutes—the first and principal Act being 3 Geo. IV. c. 126. The trustees are required and empowered to maintain, repair, and improve the roads committed to their charge, and the expenses of the trust are met by tolls levied on persons using the road. The various grounds of exemption from toll on turnpike roads are all of a public character, e.g., horses and carriages attending the sovereign or royal family, or used by soldiers or volunteers in uniform, are free from toll. In general horses

and carriages used in agricultural work are free from toll. By the Highways and Locomotives Act of 1878 (41 and 42 Vict c 77) distinguished roads are to become "main roads," and half the expense of maintenance is to be paid out of the county rate. Ordinary highways may be declared to be "main roads," and "main roads" may be reduced to the status of ordinary highways.

In Scotland the highway system will in future be regulated by the Roads and Bridges Act, 1878, which comes into operation at the latest on the 1st of June 1883, but may be adopted sooner in any county. From and after the commencement of the Act in each county, the management and maintenance of the highways and bridges shall be vested in the county road trustees, viz., the commissioners of supply, certain elected trustees representing ratepayers in parishes, and others. One of the consequences of the commencement of the Act is the abolition of tolls, statute labour, conveyance mail, and other exactions for the maintenance of bridges and highways, and all turnpike roads shall become highway, and all highways shall be open to the public free of tolls and other exactions. The county is to be divided into districts under district committees, and county and district officers are to be appointed. The expenses of highway management in each district (or parishes), together with a proportion of the general expenses of the Act, shall be levied by the trustees by an assessment on the lands and houses within the district (or parishes).

Highway, in the view of the States of the American Union, generally means lawful public road, over which all citizens are allowed to pass and repass on foot, on horseback, in carriages, and waggons. Sometimes it is held to be restricted to county roads as opposed to town ways. In statutes dealing with offences connected with the highway, such as gaming, negligence of carriers, &c., "highway" includes navigable rivers. But in a statute punishing with death robbery on the highway, railways were held not to be included in the term. In one case it has been held that any way is a highway which has been used as such for fifty years.

(P. 3.)

HILARION, Sr, abbot, the first to introduce the monastic system into Palestine, was born of heathen parents at Tabitha, about 5 miles to the south of Gaza, about the year 288, was sent when very young to Alexandria to be educated, and there became a convert to the Christian religion. Attracted by the fame of St Anthony, he went to visit that saint in his solitude, and forthwith became a disciple. Returning to Palestine with some companions while he still, but a lad of fifteen, gave away all the property he had inherited by the recent death of his parents, and then withdrew into loneliness in the desert between the sea and the mountains on the Egyptian border. In this solitude he observed the most rigid asceticism, and (to quote the quaint remark of Butler) "thought himself at liberty to practise certain mortifications which the respect we owe to our neighbour makes unreasonable in the world." Twenty years of patient continuance in the way of life he had chosen for himself were rewarded, we are told, with miraculous gifts and with rapidly growing fame, disciples and imitators multiplied to the number of two or three thousand, and all owned the spiritual oversight of Hilarion. Informed by revelation when sixty-five years old of the death of Anthony, he undertook an extended tour into Egypt, where he visited all the scenes of that saint's labours. He was removed in the company of a favourite disciple, Hesychius, into Sicily, where, however, his popularity rendered impossible the quiet and retirement which were congenial to his habits, a further migration to Epidaureus thus became necessary, and ultimately he found a resting-place in Cyprus, the diocese of his old friend Epiphanius, where in a lonely cell amongst some almost inaccessible

rocks he died in 371. According to Sozomen his festival was observed in Palestine with great solemnity as early as the 5th century, he is now commemorated by the Roman Church on October 21st. His earliest biographers were Epiphanius and Jerome.

HILARIUS, or HILARUS (HILANUS), bishop of Rome from 461 to 467, who according to some authorities had attained to the archiepiscopate as early as the year 417, is known to have been a deacon and to have acted as legate of Leo the Great at the "robber" synod of Ephesus in 449. There he so vigorously defended the conduct of Flavian in deposing Eutyches that he was thrown into prison, whence he had great difficulty in making his escape to Rome. Chosen to succeed Leo on November 12, 461, he issued a brief *de fide catholica*, in which he anathematized Eutyches, Nestorius, and Dioscorus, and reaffirmed the decisions of the councils of Nice, Ephesus, and Chalcedon. In 465 he held at Rome a council which put a stop to some prevalent abuses, particularly to that of bishops appointing their own successors. His pontificate was also marked by a successful encroachment of the papal authority on the metropolitan rights of the French and Spanish hierarchy, and by a resistance to the toleration of Arius, which ultimately caused it to be recalled. Hilarius, who died November 17, 467, was succeeded by Simplicius.

HILARIUS, Sr, of Ailes (c. 403-449), an eminent prelate and an able if unsuccessful defender of the liberties of the Gallican Church, was born about 403, and in early youth entered the abbey of Loin, then presided over by his kinsman Honoratus (St Honoré). Having succeeded Honoratus in the bishopric of Ailes in 429, he set about the discharge of his episcopal functions with unusual energy and zeal. Following the example of St Augustine, he is said to have organized his cathedral clergy into a "congregation," devoting a great part of their time to social exercises of ascetic religion. As bishop of Ailes he held the rank of metropolitan of Vienna and Narbonne, and in this capacity he came into collision in 444 with Leo the Great on the question of the deposition of one of his bishops (Chlorionus), this quarrel resulted in his being deprived of his rights as metropolitan to consecrate bishops, all synods, or exercise ecclesiastical oversight in the province, and in the edict of Valentinian III, so important in the history of the Gallican Church, "ut episcopus Galliarum omnibusque pro lege esset quidquid apostolicæ sedis antea iuris sanxisset." He died in 449, and his name was afterwards introduced into the Roman martyrology for commemoration on the 5th of May. Hilarius enjoyed during his lifetime a high reputation for learning and eloquence as well as for piety, his extant works (*Vita S. Honorati Arvernenis Episcopi et Metrum in Germanum*) compare favourably with any similar literary productions of that period. A poem, *De Providentia*, usually included among the writings of Prosper, is sometimes also attributed to Hilary of Ailes.

HILARIUS, Sr, bishop of Pictavium (Poitiers), an eminent "doctor" of the Western Church, sometimes referred to as the "malleus Arrianorum" and the "Athanasius of the West," was born at Poitiers about the end of the 3d century A.D. His parents, who were pagans of distinction, afforded him every means of acquiring a good education, and to the ordinary accomplishments of an educated gentleman there was added in his case what had even then become somewhat rare in the West, some knowledge of Greek. After he had attained to manhood his attention was directed to the study of the Old and New Testament writings, with the result that he became conversant of the truth of Christianity, and along with his wife and his daughter received the sacrament of baptism. We have no means of knowing the nature or duration of the services which he rendered the church during the period which im-

mediately followed his admission within its pale, but he appears to have continued to reside in Pottius, and so great was the respect in which he came to be held by the citizens there that about 353, although still a married man, he was by the unanimous voice elected bishop. At that time Arianism, which under imperial protection had over-spoken the Eastern, was now under similar auspices threatening also to overrun the Western Church, to resist and repel the triumph was the great task which Hilary now set himself to achieve. One of his first steps was to secure the excommunication, by those of the Gallican hierarchy who still remained orthodox, of Saturninus, the Arian bishop of Arles, along with Ursinus and Valens, two of the most prominent of the supporters of that schism. About the same time he wrote to the emperor Constantine a remonstrance against the persecutions by which the Arians had sought to crush their opponents (*Ad Constantium Augustum Liber Primus*, of which the most probable date is 355). His labours for the triumph of orthodoxy were not in the first instance, however, crowned with success, for at the synod of Bileto (Boziers), summoned in 356 by Constantius with the professed purpose of settling the long-standing disputes, Hilary was by an imperial rescript banished along with Rhodanus of Toulouse to Phrygia, in which exile he spent nearly four years. From this hostile region, however, he continued to govern his diocese without undue difficulty, no success having been nominated to the see, while at the same time he found leisure for the preparation of two of the most important of his contributions to dogmatic and polemical theology, the *De Synodo*, or *De Fide Orientalium*, an epistle addressed in 358 to the bishops in Gaul, Germany, and Britain, expounding the true views (sometimes veiled in ambiguous words) of the Oriental bishops on the Trinitarian controversy, and the *De Trinitate Libri XII*, composed in 359 and 360, in which, for the first time, it was successfully attempted to express in the Latin tongue the theological subtleties and refinements which had been elaborated with the aid of the more flexible language of Greece. The former of these works was not entirely approved by some of the members of his own party, who thought he had shown too great forbearance towards the Arians, and had expressed himself too hopefully as to the possibilities of an ultimate reconciliation of the contending views, to their criticisms he replied in the *Apologetica ad Reprehensores Libri de Synodo Responsa*. In 359 Hilary attended the convocation of bishops at Seleucia in Isauria, where, along with the Egyptian Athanasians, he joined the Homoiousian majority against the Arianizing party headed by Acaecius of Caesarea, thence he betook himself to Constantinople, and, in a petition (*Ad Constantium Augustum Liber Secundus*) personally presented to the emperor in 360, repudiated the personal calumnies of his enemies and sought to vindicate his Trinitarian principles. His urgent and repeated request to be permitted a public discussion with his opponents, especially with Ursinus and Valens, proved at last so inconvenient that he was sent back to his diocese, which, accordingly, he appears to have reached about 361, within a very short time of the accession of Julian. Though he was received in his diocese with every demonstration of joy, he yet found Arianism strong enough there to demand his best energy and skill for the next two or three years, but in 364, extending his efforts once more beyond Gaul, he impeached Auxentius, bishop of Milan, and a man high in the imperial favour, as heretic. Summoned to appear before the emperor (Valentinian) at Milan and there maintain his charges in person, Hilary had the mortification of hearing the supposed heretic give answers entirely satisfactory to all the questions which were proposed, nor did his (doubtless sincere) denunciation of the metropolitan as a hypocrite save himself from an

ignominious expulsion from Milan as a disturber of the peace of the church. In 365 he published the *Contra Arianos vel Arianismum Melanienus Liber*, in connexion with the controversy, and also (but perhaps at a somewhat earlier date) the *Contra Constantium Augustum Liber*, in which he pronounced that lately deceased emperor to have been Antichrist, a rebel against God, "a tyrant whose sole object had been to make a gift to the devil of that world for which Christ had suffered." The later years of Hilary's life were spent in comparative quiet and retirement, devoted in part to the preparation of his expositions of the Psalms (*Tractatus super Psalmos*), for which he was largely indebted to Origen, of his *Commentarius in Evangelium Matthaei*, a work of no exegetical value, and of his no longer extant treatise on the book of Job. He died 13th January 368. His great energy and zeal, courage and perseverance, rendered him a very influential ecclesiastical during his life, while, in virtue at once of the depth and earnestness of his intellect and of the wide extent of his knowledge, he holds the very highest rank among the Latin writers of his century. Designated already by Augustine as "the illustrious doctor of the churches," he by his works created an increasing influence in later centuries, and by Pius IX. he was formally recognized as "universal ecclesiae doctor" at the synod of Bordenax in 1861. Hilary's day in the Roman calendar is January 14, the English "Hilary Term" begins on the 11th and ends on the 31st.

Of Hilary's works, which include, besides those already mentioned, some minor treatises, that have been translated into English the most worthy of mention are those of Erasmus (Basel, 1528, 1529, 1528), the Benedictees by Contant (Paris, 1693), reprinted by Milla, Vescom, 1780), and that of Migne in the *Patrologia Curiae Complutensis*. His biography by Teulinius probably dates from about the middle of the 8th century, other sources for the facts of the life of Hilary are the numerous incidental notices to be met with in his own writings and in those of Jerome, Sulpicius Severus, and Gregory of Tours. See Henkenius, *Hilarius v. Poitiers* (1864).

HILDA, or HILD (614–680), usually called St Hilda, a Saxon lady whose name is intimately associated with the history of the early English church and of early English literature. She was a member of the royal family of Northumbria, her father Hereric being a nephew of King Edwin, and it was along with her royal kinsman that, as a girl of fourteen, she received baptism at the hands of Paulinus. During the pagan reaction which followed Edwin's defeat and death, Hilda was tempted to settle with her widowed sister Herswith at the monastery of Chelles, 13 miles from Paris, but she was recalled to England by Bishop Aidan, the missionary from Iona, and in 649, two years after her consecration as a nun, she was appointed to succeed Heru the abbess of Eborac or York. When, in fulfilment of the vow which she had made before the decisive battle with Penda, Oswy came to dedicate his daughter to God, it was to the care of Hilda that he entrusted her. In 658 the abbess founded the famous monastery on the cliffs at Streonshalh or Whitby, and for the next twenty-two years she ruled with rare ability and virtue over the double community of monks and nuns which gathered round her. Among those who shed the most abiding lustre on the establishment were St John of Beverley and the Saxon poet Caedmon. Hilda died, full of years, in 680, mourned by her nuns as their common mother. There is a St Hilda's church both of South Shields and at Hartlepool, and the latter preserves her effigy on its ancient stone forenoon, when the sun shone in the highest windows of the north part of the abbey, a figure of Lady Hilda could be discerned, and the fossil ammonites of the neighbourhood are popularly known as St Hilda's snakes. See Bede, *Ecc. Hist.*, xxiv, Dr G. Young, *Hist. of Whitby*, 1817, Sir Outhbert Sharp, *Hist. of Hartlepool*, 1816.

HILDEBURGHUSEN (in old record: *Hilperhusen* and *Helpehusen*), the chief town of a circle in the duchy of Sax-Meiningen (Germany), is situated in a wide and fruitful valley on the river Werra and on the Werra railway, 19 miles south-east of Meiningen by rail. It is the seat of a circle court, of a court of appeal, and of the jury court for the duchy. The streets are wide and regular, and the principal buildings are the former castle of the duchy, erected 1643-57, now used as barracks, with a park in which there is a monument to Queen Louise of Prussia, the old town house, the Government buildings, the gymnasium erected in 1877, the normal seminary, and the lunatic asylum. A monument has been erected to those of the citizens who died in the Franco-Prussian War of 1870-71. The manufactures are very various, and include linen fabrics, cloth, paper mills, knives, buttons, optical instruments, agricultural machines, toys, mineral water, condensed soups, and condensed milk. The population in 1873 was 5162.

Hilburghusen belonged in the 11th century to the counts of Thuringia, from whom it passed into the possession of the dukes of Saxony. In 1481 it became the capital of a principality, which in 1640 was united to Sax-Meiningen.

HILDEBERT (Hilbertus, Hiltebert, Aldelbertus) of Lo Mans, and afterwards of Tours, a prominent church leader, and one of the best Latin writers of his century, was born about 1035 at Landavin near Vendôme, became a pupil of the famous Beaugrandis of Tours, and made so great progress in all the learning of the time that he was made head master of the school, archdeacon, and finally, in 1077, bishop of Lo Mans. In the beginning of his episcopate much trouble was caused him by the jealousy of his dean, Adolphe, who had accused him of immorality, but finally he succeeded in fully vindicating his innocence. He next had to encounter the persecutions of William Rufus, who had captured the city, and those pursued so harassing that he ultimately felt it necessary to withdraw to Rome, with the intention of resigning his charge, but Pope Paschalis II declined to give him his release. On his return to Lo Mans, Hildebert found the diocese in a state of great commotion, which had been caused by the preaching of Henry the Deacon, but he speedily succeeded in restoring order after he had banished the agitator. About 1125 he was translated, much against his will, to the see of Tours, and soon afterwards he held the important synod of Nantes, convened for the purpose of correcting the abuses and banishing the disorder which had so long prevailed in Brittany. A dispute with Louis the Fat about the rights of ecclesiastical patronage brought him into much disfavour with that monarch, but their mutual relations had much improved before the death of Hildebert, which took place on December 18, 1134. From some writers he has received the name of Saint, but his name occurs in no martyrology.

The works of Hildebert, which include letters, sermons, and poems, as well as formal contributions to philosophy and dogmatic theology, have been edited by Bonnet (Paris, 1798), and in part both by Bruns and Maitland (See also Galland's *Philosophie Patrum*, vol. xiv). The poems, which are on very various subjects, are distinguished by many fruits of metre and effects of style, but nevertheless enjoyed great popularity in their time, and were frequently used as exercises in the schools of France and Italy, as also were the letters, of which the literary merit is greater (129 in 8 books). The sermons are often elegant and instructive, but generally overloaded with unmeaning and disingenuous use of the allegorical method of interpretation. The tendency to Mysticism is strongly developed in them, and the *De Canticis Domini* has an important interest, as exhibiting the first instance of the use of the word *transubstantiation*. The *Tractatus de quatuordecim confictis carnalis et animalis* is an imitation of Boetius, and the *Metaphysica Philosophia* has its sources in earlier Latin authors, and especially in Cicero and Seneca. The *Tractatus theologicus* appears to have determined the form of later Latin systems, and has been of some use in the history of dogmatic theology. His method is first to

lay down the thesis, which is then supported by scriptural proofs and by passages from the fathers, especially from Augustine, he finally proceeds by detailed argument to dispose of difficulties and objections with careful consistency, and without that excessive subtilty which distinguished later scholastic writers.

HILDEBRAND See GILBERT VII.

HILDEBRANDUSLIED This invaluable example of Old German alliterative poetry is contained in a MS originally belonging to the library of Fulda, and now preserved at Cassel. It is written on the first and last pages of a volume of Biblical and theological contents by two contemporary hands apparently belonging to the beginning of the 9th century. The conclusion of the poem is unfortunately wanting, evidently from want of space. From such misreadings as *mun* for *man*, and *pass* for *was* or *was* (with *u* for the Rime) so sign sometimes used here as in Old English MSS), it is manifest that our text was not written down from memory,—as has often been assumed,—but is a transcript from an older original. This conclusion is confirmed by the state of the language of the fragment, which shows a curious mixture of Low and High German forms that can never have existed in any living dialect of Germany, but can only be explained as the result of an attempt made by a Low German scribe to adapt the forms of a High German original to his vernacular idiom.

The fragment is mostly taken up with a dialogue between Hildebrand and his son Hadubrand. When Hildebrand followed his master Theodoric the Great, exiled from Italy by Odaccer, he left his young wife and an infant child behind him. At his return to his old home, after thirty years' absence at the Hunnic court, he is met by a young warrior and challenged to single combat. Before the fight begins, Hildebrand, asking for the name of his opponent, and discovering his own son in him, tries to avert the fight, but in vain. "Then they let their horses run with their sharp spears, and then they hewed that white shields until they were beaten to pieces with their weapons." With these words the fragment stops abruptly, giving no clue as to the issue of the combat. It is certain, however, from allusions to the tale in the Old Norse *Amundar* Saga, that it must have been fatal to Hadubrand.¹ But in the later traditions both of the Old Norse *Thidrik* Saga (13th century), and the so-called *Jungere Hildebrandslied*,—a German popular song preserved in several versions dating from the 15th to the 17th century, but evidently originating at an earlier time,²—Hadubrand is represented as defeated simply, and obliged to recognize his father.

The *Hildebrandslied* was discovered and published for the first time as a poem in 1795, as early as 1799,³ but it was not till 1812 that its metrical character was recognized by the brothers Grimm.⁴ Since that time numerous reprints and critical editions have been published, among which Lechmann's text.⁵ holds the foremost rank as to critical exactness and sagacity, although some of the metrical rules laid down by Lechmann, and followed in his text, have since been shown not to be applicable to the Old German alliterative verse in which the *Hildebrandslied* is written.

HILDEBRANDT, EDWARD (1817-1868), was born in 1817, and served his term as apprentice to his father, a house-painter at Dantzig. He was not twenty when he came to Berlin, where he was taken in hand by Wilhelm

Krause, a painter of sea pieces. Like other artists who have owned a name for subtle and rapid execution, he worked at first in a formal, smooth, and timid fashion. Several early pieces exhibited after his death,—a breakwater, dated 1838, ships in a breeze off Swinsmunde (1840), and other canvases of this and the following year,—show Hildebrandt to have been a careful student of nature, with inborn talents kept down by the conventionalisms of the formal school to which Krause belonged. It is difficult to say what the outcome of his art would have been if Hildebrandt had not felt other influences than those of his native schools. Accident made him acquainted with masterpieces of French art displayed at the periodical exhibitions of the Berlin Academy, and these awakened his curiosity and envy. He made up his bundle and wandered to Paris, where, about 1812, he entered the atelier of Isabey and became the companion of Lepoittevin. In a short time he sent home pictures which might have been taken for copies from those artists. Gradually he mastered the tricks of touch and the mysterious secrets of effect in which the French at this period were already so perfect. He also acquired the necessary skill in painting figures, and having done this he returned to Germany, unsurpassable in technical execution, and well skilled in the rendering of many kinds of landscape forms. His pictures of French street life, done about 1843, are impressed with the stamp of the Paris school, but they reveal at the same time a spirit eager for novelty, quick at grasping equally quick at rendering momentary changes of tone and atmosphere in varying speed and medium. After 1843 Hildebrandt, under the influence of Humboldt, extended his travels, and in 1864-65 he actually went round the world. But whilst his experience became enlarged his powers of concentration broke down. He lost the taste for detail in seeking for scenic breadth, and a fatal facility of hand diminished the value of his works for all those who look for composition and harmony of hue as necessary concomitants of tone and touch. In oil he gradually produced less, in water colour more, than at first, and his fame will probably rest on the sketches which he made in the latter form, many of which are known to the general public by means of chromo-lithography. His course may best be compared to that of a meteor, being breathlessly rapid, brilliant, and charged with colour. No other had the same art of combining elements singly picturesque into a picturesque and striking whole, and this chiefly by contrasts of tint and observation of natural phenomena. Fantasies in red, yellow, and opal, sunset, sunrise, and moonshine, distances of hundreds of miles like those of the Andes and the Himalaya, narrow streets in the bazaars of Cairo or Sues, panoramas as seen from mastheads, wide vistas like Bombay or Peking, narrow strips of desert with measureless expanses of sky,—all alike display the *bravura* of a master who had no unimpaired admirers in his day on account of this facility, and deserved all the admiration he received, subject to the merited reproach that all these fine works would have been more satisfactory if combined with deeper meditation on the art of composition and more patient study of detail. Hildebrandt died young at Berlin, on the 25th of October 1868. His pictures are scattered in vast numbers throughout Germany. But good selections are accessible in the royal palaces and in the collections of Boreig, Rarba, and Ravene at Berlin.

HILDEBRANDT, THEODOR (born at Stettin 1804, died at Düsseldorf 1874), was a disciple of the painter Schadow, and, on Schadow's appointment to the presidency of a new academy in the Rhénish provinces in 1828, followed that master to Düsseldorf. Bred in the academy of Berlin, and finished under Schadow (1820-84), Hildebrandt began by painting pictures illustrative of Goethe and Shakespeare, but in this form he followed the traditions of the stage

rather than the laws of nature. His artificial modes of thought were not, however, without admirers, and he produced rapidly Faust and Mephistopheles (1824), Faust and Margaret (1825), and Lear and Cordelia (1828). He visited the Netherlands with Schadow in 1829, and wandered alone in 1830 to Italy, but travel did not alter his style, though it led him to cultivate alternately eclecticism and realism. At Düsseldorf, about the year 1830, he produced Romeo and Juliet, Tancréd and Clotilde, and other works of the same kind which deserved to be classed with earlier ones, but during the same period he exhibited (1829) the Robber and (1832) the Captain and his Infant Son, examples of an affected but kindly realism which captivated the public of the time, and marked to a certain extent an epoch in Prussian art. The picture which made Hildebrandt's fame is the Murder of the Children of King Edward, of which the original, afterwards frequently copied, still belongs to the Spiegel collection at Hallestadt. It challenges comparison with a similar composition by Paul Delaroché, though rather to Hildebrandt's disadvantage. Hildebrandt chose the moment when the children are asleep, and the murderers pause ere they smother their victims with a pillow. Delaroché with subtler sense of artistic propriety represented the pinnaces seated on their bed, unconscious of the near approach of their assassins, whose vicinity is betrayed by a streak of light at the bottom of the door and the watching of a dog. The execution of Delaroché is spirited and delicate, that of Hildebrandt finished and smooth. But the German master, who was below Sohn and Schadow in power, is also naturally far below his French competitor. Comparatively late in life Hildebrandt tied his powers as an historical painter in pictures representing Wolsey and Henry VIII., but he lapsed again into the romantic in Othello and Doedemona, a fair replica of which, in Schulte's collection at Düsseldorf, gives a good idea of his shiny, ineffective, technical execution. After 1847 Hildebrandt gave himself up to portrait painting, and in that branch succeeded in obtaining a large practice.

HILDEGARD (1098-1179), commonly referred to as St Hildegard, abbess, "prophetess," and a figure of some consequence in the history of mediæval mysticism, was born of noble parents at Dischelsheim in the county of Sponheim, diocese of Mainz, in 1098 (or 1099), and from her eighth year was educated at the Benedictine cloister of Disibodenberg (Mons Disibodi) in the principality of Zweibrücken, now in Rhénish Bavaria, where Jutta, sister of the count of Sponheim, was at that time abbess. From earliest childhood, we learn from Hildegard herself, she was accustomed to see visions which increased in frequency and vividness as she approached the age of womanhood, these, however, she for many years, though with great pain, kept almost wholly secret, nor was it until she had reached her forty-third year (1141) that she felt constrained at last to divulge them. Committed to writing by her intimate friend the monk Godefridus, they now form the first and most important of her painted works, entitled *Scenes* (probably an abbreviation for "visions vias" or "nostra vias Domini") a *Tractatus de Revelationibus Libris III*, and completed in 1151. In 1147 St Bernard of Clairvaux, having come to Bingen while engaged in preaching the new crusade throughout Germany, chanced to hear of Hildegard's revelations, and on inquiry became so convinced of their reality that he not only wrote to her a letter cordially acknowledging her as a prophetess of God, but also successfully advocated her recognition as such by his friend and former pupil Pope Eugenius III. in the synod of Trèves (1148). In the same year Hildegard, who meanwhile had succeeded Jutta as abbess at Disibodenberg, and had attracted overflowing numbers to that

clouster, migrated along with eighteen of her nuns to a new convent at Ruppertsberg near Bingen, over which she presided during the remainder of her life. By means of voluminous correspondence, as well as by extensive journeys, in the course of which she was unwearied in the exercise of her gift of prophecy, she wielded for many years an increasing influence upon her contemporaries,—an influence doubtless due to the fact that she herself was so fully imbued with the most widely diffused feelings and beliefs, fears and hopes, of her time. Amongst her correspondents were Popes Anastasius IV and Hadrian IV, the emperors Conrad III and Frederick I, and also the theologian Guibert of Gembloux, who submitted numerous questions in dogmatic for her determination. It deserves to be specially mentioned to her credit that, though zealously opposed to the Catholics, she stood almost alone in maintaining that the image of God ought to be respected even in them, and that therefore they ought not to be killed. She died in 1179, but has never been canonized, her name, however, was received into the Roman martyrology in the 15th century, September 17th being the day fixed for her commemoration. Her biography, which was written by two contemporaries, Godefridus and Theodoricus, was first printed at Cologne in 1566, and has frequently been reproduced in various forms since that date.

The works of Hildegard, in addition to the *Scopus*, already mentioned, include *Disputationes super viis sancti Augustini*, a letter to unpublished friends containing later visions and revelations, many of them relating to physical and medical questions, *Vita meritoria*, also unpublished, *Liber de Regibus* and *de Senectute*, *Epistolarum* of the 15th century, *De Christiana erede*, *Lettere*, and *Exhortationes*. While her "visions" on such themes as the Christian religion as God and His kingdom, the church and its my spiritual union to Christ, must be regarded as crude and extravagant even to us, it is impossible to deny all ethical or religious value to her earnest denunciations of the corruptions of the clergy and mendicant orders, or to the intense expositions (however ignorant and unimpaired) of the life long expiations of a man so singularly unselfish and unworldly as she. The *Scopus* was printed in 1513 and again in 1628. The *Epistolarum Liber* (first published in 1760) appears with some other *Opuscula* in the *Arch. Bibl. Pfa. Pfa.*, vol. xviii, and in *Milnes and Darwin's Anglo-Saxon Collected*, vol. i. The *Opera Omnia* (first ed. 1891), *Migne's Patrologia Latina* (1891), *De Sanctis Hildegardis* (1891), *De vita, rebus, et scriptis* (1891), *De vita Hildegardis* (1891), *De vita Hildegardis* (1891).

HILDEN, a town of Prussia, in the government and circle of Düsseldorf, on the Itterbach. It is a station on the Rhensish railway, and has a considerable manufacture of silks, both pure and mixed, calico, and machinery, it also possesses a deaconess institute. During the last half century its growth has been rapid. While in 1816 the population numbered only 2056, it amounted in 1875 to 6789. Hilden was constituted a town in 1861.

HILDESHIM, the chief town of a district in the province of Hanover, Prussia, is beautifully situated on the right bank of the Innerste, 18 miles south east of Hanover by railway. It has a very antique and quaint appearance, and is surrounded by old ramparts which have been converted into shady alleys and promenades. The streets are for the most part narrow and irregular, and contain many old houses with overhanging upper stories and richly and curiously adorned wooden façades. The town is the seat of a district governorship, a high court of justice, two justice courts, a general superintendency of the Evangelical Church, and a Roman Catholic chapter. The Catholic cathedral, which occupies the site of a building founded by Louis the Pious in 818, dates from the middle of the 15th century. Its exterior is remarkable for the antiquities and notable works of art connected with it, including the bronze doors executed by Bishop Bernward, with reliefs from the history of Adam and Christ, the so-called *Irmsausla*, at one time believed to have been

erected, before it was transferred to its present site, in honour of the Saxon idol Irmin, but now regarded as belonging to an old Roman aqueduct, the Christ column by Bishop Bernward, adorned with reliefs from the history of the Saviour, a basen font of the 13th century, two candelabra of the 12th century, the sarcophagus of St Goddard, the tomb of St Epiphanius, and an immense number of minor articles of ecclesiastical furniture. The rose-bush on the wall of the crypt is alleged to be a thousand years old. Among the other churches those of special interest are St Goddard's church, completed in 1172 and restored in 1868, a remarkable fine specimen of the Romanesque style, the church of St Michael, an almost equally fine specimen of Romanesque, founded by Bishop Bernward, and restored in 1180 after injury by fire, containing a beautiful painted ceiling of the 12th century, and the tomb and monument of Bishop Bernward, St Magdalene's church, which preserves various works in metal by Bishop Bernward, St Martin's church, now used as a museum and library, the Lutheran church of St Andrew, with very lofty towers, and the fine columnar basilica of the abbey church of Moutburg, a suburb half a mile south-west of the town. The other principal buildings are the town-house, dating from the 15th century, and containing the archives of the town, the houses in the late Gothic style, and, not uncommonly, to have been built by the Knights Templars, the Michaels monastery, now used as a lunatic asylum, and the Cuthasian monastery. The educational establishments include a Catholic and a Lutheran gymnasium, a Catholic normal school, a weaving school, and an agricultural school. The other principal public institutions are the Geostigst for daughters of state servants, the maternity hospital, two orphanages, and several other hospitals and infirmaries. The town has iron foundries, manufactures of cloth, damasks, linen fabrics, thread, sail-cloth, wadding, leather, machines, carriages, stoves, glass, tobacco, alcohol, perfumery, chocolate, and starch. The population in 1875 was 22,681.

Hildesheim, though previously in existence, owes its rise and prosperity to the translation to it in 822 of the bishopric instituted by Charlemagne at Elze in 812. In the 10th century its importance was largely increased under Bishop Bernward, who, if he did not introduce, greatly stimulated by his example and patronage the art of working in metals, for which the town received a high reputation until the close of the Middle Ages. It also obtained considerable fame by its cathedral school, at which several sons of the emperors received their education. In 1241 it joined the Hanseatic League, and in 1249 received town rights. It was frequently at feud with its bishops, and in the 14th century placed itself more than once under the protection of the house of Brunswick-Lüneburg. The bishopric in the course of time had acquired considerable territory, but their feuds with the neighbouring princes resulted in 1523 in the annexation of a great part of their possessions to Brunswick. A reformation, however, took place in 1648, and in the beginning of the present century the principality amounted to 682 square miles. The last bishop of Hildesheim possessed also the bishopric of Paderborn, acquired by his predecessor. Both bishoprics were secularized and ceded to Prussia in 1803. In 1807 they were incorporated with the kingdom of Westphalia. In 1815 they were ceded to Prussia, which ceded Hildesheim to Hanover, retaining only Paderborn. In 1866 the principality was united, along with Hanover, to Prussia.

On October 2, 1868, a unique collection of ancient plates was discovered on the Galgenberg near Hildesheim, about 10 feet below the surface. This *Hildesheimer Silberfund*, as it is usually called, has excited great interest among classical archaeologists, comprising as it did no less than 60 pieces of a very fine silver, worth three persons—plates, dishes, mixing bowls, &c. The workmanship evidently belongs to the Augustan age, and by some authorities it is conjectured that we have nothing less than the plate that belonged to Drusus himself. The most noteworthy of the pieces are—a silver richly ornamented with arabesques and figures of children, a plate with a representation of Minerva, and others with a boy Hercules, a Cybele, and a Dea Luna. The whole collection is preserved in the Museum. For details see *Wissener, Der Hildesheimer Silberfund*, Bonn, 1868.

service, in accordance with the forms of the Church of England, in whose communion he always remained. From the beginning his success was complete, and his chapel soon came to be filled with an audience such as no other preacher in London could boast. During the summer months he met what he called "gospel tours," into all parts of the country, sometimes extending them to Scotland and Ireland, and attracted wherever he went audiences as numerous and as interested as those which had crowded to hear Whitfield. After these tours he always returned with increased enthusiasm to his duties at Surrey Chapel, where he continued to officiate almost to the day of his death, 11th April 1833. The oratory of Rowland Hill, like that of Whitfield, was specially adapted for loud and uncultivated audiences, and it was equally effective although by more varied means. He possessed a voice of great power, and, according to Southey, "his manner" was "that of a performer as great in his own line as Ker or Kemble." Not unfrequently he violated the laws of good taste in the eccentricities of his wit and humour, but the intensity and purity of the purpose by which he was actuated overbore him always to retain unimpaired his moral influence over his audience. Among the various publications of Rowland Hill the best known is his *Village Dialogues*, which first appeared in 1810, and reached a 3d edition in 1830.

3653, 3654, 3655, 3656, 3657, 3658, 3659, 3660, 3661, 3662, 3663, 3664, 3665, 3666, 3667, 3668, 3669, 3670, 3671, 3672, 3673, 3674, 3675, 3676, 3677, 3678, 3679, 3680, 3681, 3682, 3683, 3684, 3685, 3686, 3687, 3688, 3689, 3690, 3691, 3692, 3693, 3694, 3695, 3696, 3697, 3698, 3699, 3700, 3701, 3702, 3703, 3704, 3705, 3706, 3707, 3708, 3709, 3710, 3711, 3712, 3713, 3714, 3715, 3716, 3717, 3718, 3719, 3720, 3721, 3722, 3723, 3724, 3725, 3726, 3727, 3728, 3729, 3730, 3731, 3732, 3733, 3734, 3735, 3736, 3737, 3738, 3739, 3740, 3741, 3742, 3743, 3744, 3745, 3746, 3747, 3748, 3749, 3750, 3751, 3752, 3753, 3754, 3755, 3756, 3757, 3758, 3759, 3760, 3761, 3762, 3763, 3764, 3765, 3766, 3767, 3768, 3769, 3770, 3771, 3772, 3773, 3774, 3775, 3776, 3777, 3778, 3779, 3780, 3781, 3782, 3783, 3784, 3785, 3786, 3787, 3788, 3789, 3790, 3791, 3792, 3793, 3794, 3795, 3796, 3797, 3798, 3799, 3800, 3801, 3802, 3803, 3804, 3805, 3806, 3807, 3808, 3809, 3810, 3811, 3812, 3813, 3814, 3815, 3816, 3817, 3818, 3819, 3820, 3821, 3822, 3823, 3824, 3825, 3826, 3827

and when failing health compelled him to resign his office in 1864, he received from parliament a grant of £20,000, and was also allowed to retain his full salary of £2000 a year as retiring pension. In 1864 the university of Oxford conferred on him the degree of D.C.L. and on the 6th June 1879 he was presented with the freedom of the city of London. The presentation, on account of his infirm health, took place at his residence at Hampstead, and he survived the ceremony only a few weeks, dying on the 27th August following. He was buried in Westminster Abbey.

HILL, Viscount (1772-1842) Rowland Hill, nephew of the Rev Rowland Hill, was born at Free, Shropshire, 11th August 1772. After receiving his early education at Ighitefield and Cheshire, he was gazetted to the 38th regiment, obtaining permission at the same time to improve himself in the knowledge of his profession in a military academy at Strasburg, where he continued after removing into the 53d regiment with the rank of lieutenant. In the beginning of 1793 he raised an independent company, and was promoted to the rank of captain. The same year he distinguished himself at the siege of Toulon, and after serving for some time on the Continent he in 1797 set out as colonel of the 90th regiment with Sir Ralph Abercromby's expedition to Egypt, where he acquired great distinction, and was wounded at the battle of Alexandria. Having in 1803 been gazetted brigadier general, he in 1808 accompanied Sir Arthur Wellesley to Spain, and from Vittoria to Vittoria, in advance or retreat, he proved himself the most indefatigable conductor of the great captain. In 1809 he was gazetted lieutenant general, and in the following year was appointed to the independent command of the second army corps of Wellington in Portugal, in 1811 he annihilated the French army under Guind at Alroyomolinos (Gacera), in recognition of which he received the order of the Bath, and for his capture of the forts of Alator, which cut off the communication between the French armies on the north and south sides of the Tagus, he was in 1814 rewarded with the title of Baron Hill of Almaraz. In 1813 he held temporarily the command of the English and Hanoverian troops in Belgium, and two years later crowned the glories of his noble career by his conduct at Waterloo, where he was at the head of the brigade which resisted and repulsed the last effort made in behalf of the French by the imperial guard. When Wellington became premier in 1828 Hill received the appointment of general commanding-in-chief, and on resigning this office in 1842 he was created a viscount. He died on the 10th December of the same year. Lord Hill was, next to Wellington, the most popular and able soldier of his time in the British service, and was so much beloved by the troops, especially those under his immediate command, that he gained from them the honourable title of "the soldier's friend." "With Hill," they used to say, "both victory and life may be ours." On the other hand, the strategic skill and military capacity he displayed in the Peninsula secured for him the not less honourable title of "the right arm of the duke of Wellington." From the first day he entered the army he displayed the germs of those qualities that afterwards secured for him fame, rank, and power—boldness that amounted to daring and was yet always under the control of calm judgment, skill equal to independent commands of the most difficult kind, and a regard for the moral and physical welfare of the army such as had never before been shown by any commander-in-chief.

The *Life of Lord Hill, G.O.B.*, by Rev Edwin Sidney, A.M., appeared in 1845.

HILLAH, a town of Asiatic Turkey in the pashalik of Baghdad, from which town it lies 60 miles to the south. It is picturesquely situated, in the midst of a very fertile

district, on both banks of the Euphrates, which are connected there by a floating bridge 450 feet in length. The estimated population, which includes a large number of Jews, varies from 6000 to much above 10,000. The bazaars are large and well supplied, and tanning, dyeing, and silk manufacture are carried on to a considerable extent. The house mart has recently declined in reputation. Hillah occupies the site of the ancient Babylon, and is to a large extent built of bricks obtained from the ruins.

HILLARD, GEORGE STILLMAN (1808-1879), an American author, was born at Machias, State of Maine, September 22, 1808. After graduating at Harvard College in 1828, he became joint rector of the Round Hill Seminary at Northampton. In 1833 he was called to the Boston bar, where he soon obtained a good practice. He was chosen a member of the common council of Boston in 1845, and he was for six months its president. In 1849 he was elected a member of the State legislature. The engrossing character of his professional and other engagements did not, however, prevent him from devoting a large portion of his time to literature. Besides editing successively the *Christian Register* (a Unitarian paper), *The Jurist*, and the *Boston Courier*, he published an edition of Spenser's works (in 5 vols., 1839), and a selection from the works of Walter Savage Landor (1856), and wrote *Six Months in Italy* (2 vols., 1833), *Life and Campaigns of George D. McClellan* (1865), a series of school books, which he met with wide acceptance, and various articles in periodicals and encyclopedias. In addition to this he made frequent successful appearances as a public lecturer. From 1867 to 1878 he was United States district attorney for Massachusetts. He died 27th January 1879.

HILLEL, a famous Jewish rabbi, sometimes called for distinction's sake HILLY, "the elder," or "the old," flourished about the time of Honor the Great. According to the Talmudists he was born of a poor Davidic family, at Babylon, apparently about the year 75 B.C. In his zeal for the study of the law he went, when already of mature age, to Jerusalem, where Shammai and Abtalion were at that time the leading teachers. While supporting himself and his family there by working as a day labourer, he was not always able to earn the fee which the porters of the Beth-Mishash or house of instruction is said to have required, but such was his ardour for learning that on one occasion on a cold December morning, having failed to obtain admission, he climbed up to the window of the classroom, where some time afterwards he was found quite buried and half frozen to death under a heavy fall of snow. He was now made free of the schools, and so great was the attendance with which his discourses were ultimately rewarded that, according to the tradition, he understood all languages, including those of the hills and the valleys, the trees and the flowers, the beasts and the demons. In his later years he succeeded the "sons of Bethsaias" in the presidency of the sanhedrin, and in this high position he became the author of several important rules of interpretation (the so called seven "middoth," see *HERMENEUTICS*), and also of some authoritative legal decisions. A contemporary, and perhaps a pupil of his, was Shammai, who became the head of a rival and at times bitterly hostile school. Dying about the year 10 A.D., Hillel was succeeded in his official position by his son Simson, and afterwards by his grandson Gamaliel I.

There is evidently a good deal of what is incredible in the above Talmudic account, for example, it is not warranted on all hands that the Talmudic statement as to Hillel's presidency over the sanhedrin is absolutely irreconcilable with what we learn from the New Testament writers and from Josephus, and must be regarded as wholly unhistorical. But after every reasonable deduction has been duly made, we still have ample traces of a strong personality, characterized by unusual sweetness and light, bent on supporting

original genius. In 1835 he succeeded Fuseli as keeper of the Academy, and he died in London on 30th December, 1839, a widower without children. Some of his best pictures remained on his hands at his decease,—such as the Angel releasing Peter from Prison (life size), painted in 1831, Una with the Lion entering Cotececa's Cave (1839), the Murder of the Innocents, his last exhibited work (1839), Comus, and Amphitrite. The National Gallery now contains Edith finding the Body of Harold (1834), Cupid Dressed, Rebecca and Abraham's Servant (1839), and St. Calixtus rescuing Sirena (from the *Fans in Queen*) (1831). Hilson's excellence as an artist is relative to the state of art in his country at the time. In a great school or period he could certainly not count as more than a respectable subordinate, but in the British school of the earlier part of this century he had sufficient elevation of aim and width of attainment to stand conspicuous and praiseworthy, and, comparatively speaking, above the level of mediocrity.

HILVERSUM, a village and commune in the Netherlands in the province of North Holland, about equally distant from Amsterdam, Utrecht, and Amersfoort, with all of which it is connected by railway. The village is well sheltered on the west and north west by a range of hills, and since 1874 it has been the seat of a hospital, the Trompenberg, for convalescents. The public buildings comprise a town-house and four churches and a synagogue, and there is a very handsome railway station. The weaving of floor cloths, horse blankets, and Hilversum stripes is the principal industry. In 1433 Hilversum was separated from Laren. In 1805 it suffered at the hands of the people of Guelderland, in 1829 from the Oran, and in 1872 from the French. The population of the village in 1840 was 5160, and in 1870 5611, while that of the commune in the same years was 5314 and 6615. Of this last number 3463 were Roman Catholics, 2327 belonged to the Dutch Reformed Church, and 236 were Jews.

H I M A L A Y A

HIMALAYA is the name given to the mountains which form the northern boundary of British India, between the 75th and 95th meridians east of Greenwich. The word is Sanskrit, and literally signifies "snow abode," from *him*, snow, and *alaya*, abode, and is well translated "snowy range," though that expression is perhaps more nearly the equivalent of *Himadri*, another Sanskrit word, derived from *him*, snow, and *daksh*, mountain, which is practically synonymous with Himalaya, and probably as often used in conversation by natives of northern India. The letter *y* in the last syllable of Himalaya is purely a consonant, and the last two syllables should be pronounced *la-yé*, the conversion of the *ay* into a diphthong being quite erroneous. The name, by transformations such as are common to all times and nations in the use of foreign words, was converted by the ancient Greeks into *Emosia* and *Imos*.

Although the term Himalaya is applied by the natives of India only to the ranges which they see covered with perpetual snow, it has been long used by European geographers to designate the whole mountain region for which the Indian has no other name than *párida*, *et c.*, "the mountains," of which the snowy ranges constitute but a small portion. The first mere cursory examination of these mountains by the older geographers rightly convinced them of the general physical unity of the mountainous region to the north of India, which in length extends from about 72° to 95° E. long, that is, between the rivers Indus and Brahmaputra, and in breadth includes the ranges between the plains of Hindustan and the upper parts of the main branches of these two great rivers. To these ranges the designation of Himalaya has by degrees been specially attached, and there is a certain convenience in still restricting the name to that part of the mountains which is accessible from British India, for this is the practical signification of it now commonly accepted.

Though it is to the area thus limited that the present article is mainly designed to refer, it will be necessary, for the correct apprehension of some of its main characteristics, to understand aright the relation which the Himalaya bears to the great mountain region beyond it, and a general description of that region thus becomes requisite.

Scientific investigation has clearly shown that, so far as the main characteristics of the mountains are concerned, the natural boundaries of the Himalayan system must be carried much farther than had at first been recognized. Considerable obscurity still involves the eastern portion of these mountains, and there is great want of precise knowledge as to their connexion with the ranges of western China,

from which are thrown off the great rivers of China, Siam, and Burmah. On the west, however, it has been completely established that a continuous chain extends beyond the Indus along the north of the Oxus, and ends in that quarter about 65° E. long. In like manner it is found that no separation can be established, except a purely arbitrary one, between the Himalaya as commonly defined and the greatly elevated and rugged table-land of Tibet, not between this last and the mountain ranges which form its northern border along the low-lying desert regions of Central Asia.

It thus appears that the Himalaya, with its prolongation west of the Indus, constitutes in reality the broad mountainous slope which descends from the southern border of the great Tibetan table-land to the lower levels of Hindustan and the plains of the Caspian, and that a somewhat similar chain, descending from the northern edge of the table-land, leads to another great plain on the north, extending far to the eastward, to the northern borders of China. Towards its north-west extremity this great system is connected with other mountains,—on the south, with those of Afghanistan, of which the Hindu-Kush is the chief, occupying a breadth of about 250 miles between the Peshawar and Kunduz, and on the north, with the mountains that flank the Jaxartes or Sir on the north, and the Thian-shan or Celestial Mountains. The eastern margin of Tibet descends to western China, and the south-eastern termination of the Himalaya is fused into the ranges which run north and south between the 95th and 100th meridians, and separate the rivers of Burmah, Siam, and western China.

Nor can any of the numerous mountain ranges which constitute this great elevated region be properly regarded as having special, definite, or separate existence apart from the general mass of which they are the component parts, and Tibet cannot be rightly described, as it has been, as lying in the interval between the two so-called chains of the Himalaya and the Kuenlun or Kara Koram. It is in truth the summit of a great protuberance above the general level of the earth's surface, of which these alleged chains are nothing more than the south and north borders, while the other ranges which traverse it are but corrugations of the mass, more or less strongly marked and locally developed.

The average level of the Tibetan table-land may be taken at about 15,000 feet above the sea. The loftiest points known on the earth's surface are to be found along its southern or Himalayan boundary, one of them falls very little short of 30,000 feet in elevation, and peaks of 20,000

feet abound along the entire chain. The plains of India, which skirt the Himalayan base of the tableland, for a length of rather more than 1300 miles, along the northern border of British India, nowhere rise so much as 1000 feet above the sea, the average being much less. The low lands on the north, about Kashghur and Yarkand, have an elevation of from 3000 to 1000 feet, and no part of the Central Asiatic desert seems to fall below 3000 feet, the like of this not being somewhat above that level. The greatest dimension of the Tibetan mountain area from east to west may be about 3000 miles, while its average breadth some what exceeds 500 miles, about 100 miles on either side constitute the sloping faces, the central table land having a width of about 200 miles on the west and probably 500 miles at its eastern border.

The southern portion of the Tibetan table land throws off its waters to the north west and south-east from a central line almost on 83° E long, the Indus flowing in the former direction, and the Brahmaputra in the latter. These two rivers maintain their courses for a great distance in opposite ways, longitudinally, along the summit of the table land, they receive as they proceed the drainage of a large portion of its surface, and their accumulated waters are at length discharged by two openings in the Himalayan slope across the plains of Hindustan into the Indian Ocean. With the one exception of the basin of the Sutlej, the Tibetan area that discharges itself southward at points intermediate between the debouchure of the Indus and that of the Brahmaputra is comparatively insignificant. No important part of the drainage of the table land, so far as is yet known, passes in the opposite direction through the northern slope to join the rivers which flow from that slope to the Central-Asiatic plains. The waters of the southern slope, together with the drainage of the exceptional Tibetan area above referred to, traverse the Himalaya more or less directly, and constitute the main tributaries of the Indus, the Ganges, and the Brahmaputra.

Thus the northern border of the table land, or the summit of its northern slope, so far as it is known, seems to form the real watershed between the rivers that flow to the Indian Ocean and those that lose themselves in the plains of Turkistan and Mongolia. The summit of the Himalayan slope forms a subordinate watershed, separating the rivers that fall into the Indian Ocean into two classes, those that pass directly through the Himalaya to the plains of India, and those that are collected on the summit of the table land and discharged, also through the Himalaya, by two concentrated streams at distant points towards the opposite ends of the chain. It has been proposed to call these dividing lines, respectively, the Turkish and the Indian watershed.

The waters that issue from the Himalaya to the west of the 77th meridian combine to form the Indus. Between the 77th and 83th meridians all the streams fall into the Ganges, and eastward of the 88th meridian into the Brahmaputra. Of the continuity of the Brahmaputra, beyond the point up to which it has been explored from Assam, with the Tibetan river called on the maps Sampooc, Tsou tsangpo-tchou, and so forth, there is no room for doubt. The correct Tibetan name for the river is Tschok tsangpo, i.e., "Horse-river," or simply "Tsangpo," i.e., "Great river,"—the word "tsangpo" being applied exactly like the corresponding Indian term "ganga," or the Chinese "kyang," as a generic affix to the name of any large river. In the mountains on the border of Assam the river is called "Dihong," but on entering the plain it receives the waters of the sacred stream locally called "Lohit," which is also believed to have a Tibetan source, and thus name the united river retains throughout the greater part of its

course in Assam, Brahmaputra being a classical Sanskrit name not commonly used. In its course through Bengal local names are given to the various branches into which it then divides, and this is also the case with the Ganges, which unites with the Brahmaputra about 100 miles from the sea. That part of Tibet which lies north of the 30th parallel of latitude and between the 82d and 92d meridians is believed to have no escape open for its waters, which are consequently collected in lakes occupying depressions on its surface. The region east of the 92d meridian, excluding the comparatively small tract which drains into the Brahmaputra, feeds the great rivers of

western China, Siam, and Burmah. At the western extremity of the Tibetan table-land two transverse watershed lines are established in connexion with it, by mountain ranges nearly at right angles to what may be regarded as its general direction in this region,—first, on the south by the mountains which under the name of Hindu Kush form the north east angle of the high land of Afghanistan, and from the north-west of which the waters flow into the Oxus (the true Turki name of which is "Anu"), and thence to the Aial Sea, while those from its south eastern face join the Indus through the Cabul river, and second, on the north by the Tschok-tagh, which unites the Tibetan system with the mountains of northern Turkistan, and separates the Jaxartes (in Turki "Sir") from the basin of Yarkand. The Oxus and Jaxartes flow off to the Aial Sea in a north westerly direction, leaving between them a range which probably represents the extremity of either the Tibetan or the Thian-shan mountains, and which falls away into hills of minor importance beyond the 70th meridian.

Some further particulars of the relations of the Tibetan-Tibeto Himalayan region with the contiguous mountain systems, and of its influence both physical and political on the Asiatic continent in the heart of which it is situated, are contained in the article ASIA, to which reference may be made. A more detailed account of Turan will be given under that heading, and the remainder of this notice will be confined to the description of the restricted Himalayan area, as already defined.

The northern provinces of British India occupy the great plain which flanks the Himalaya on the south, along its whole extent from the issue of the Brahmaputra on the east to the ranges that lie along the Indus. The whole tract, excepting Assam, i.e., the valley of the Brahmaputra, India is highly cultivated and populous, and with the same exception the population throughout is of the race known as Aryan, being almost exclusively Hindu in religion on the east, but passing into Mahomedan on the west.

The most eastern portion of the Himalayan mountain slopes, as far as the 92d meridian, is occupied by wild tribes of which, or of the country they occupy, little is known. They are in small communities under petty chiefs, and their languages, which vary considerably in detail, are to some extent allied to Tibetan and monosyllabic between the 92d and 89th meridians is the small state of Bhootan, the local name of which is "Lhopot." It approximates in language, customs, and religion to Tibet proper, and its government is carried on by two separate chiefs, temporal and spiritual. Its northern border, where it is met by Tibet, lies along the 28th degree of north latitude. The small British district of Sikkim succeeds, occupying the lower part of the basin of the Teesta river, and having Darjeeling as its chief settlement. The native state of Sikkim, in Tibetan called "Demong," extends north of Bhootan, and still less important. Its western border falls nearly on the 88th meridian.

From the 88th nearly to the 80th meridian the whole southern slope is occupied by the kingdom of Nepal, which

(LITHOGRAPHED BY THE GOVERNMENT OF INDIA)

since the wars with the British in 1814-16 has retained complete independence. The policy with which its government has excluded Europeans from most parts of the country leaves us with little precise knowledge of any part of it except its eastern border and the neighbourhood of the capital, Kathmandu. The people pass from the Tibetan and Buddhist type, which prevails on the east, into almost pure Hindus, speaking a Hindi dialect, on the west. The rivers Kosi, Gandak, Rapti, and Karnali are the principal streams that issue from this part of the mountains. The northern border of Nepal follows the main watershed, and its western angle reaches the 30th parallel of north latitude in the vicinity of the well-known Tibetan lakes Rakas tal and Manassarovar, where the general direction of the mountains lay, from east and west, become nearly south east and north-west.

The Kāh or Sāda river forms the boundary between Nepal and the British provinces of Kumaon and Garhwal, the chief town in which is Almora, and which occupy the entire mountain face, from the watershed to the plains, as far as the main stream of the Ganges, for a distance from east to west of about 100 miles. Thence, an equal distance brings us to the Sutlej, the intermediate tract being occupied by many small principalities, independent in their civil government, but entirely under the political control of the British. In this region is situated Simla, the summer capital of the government of British India, one of the outer ranges overlooking the Sutlej. Other small districts and principalities, partly British, occupy the Himalayan slope as far as the 70th meridian, beyond which we reach the territories of Jammu and Kashmir, which extend to within 50 miles of the Indus, a narrow band bordering on which river is mainly in the possession of Afghan tribes but partly under British rule. From the portion of the mountains west of the 79th meridian issue the rivers Ganges and Jumna, also the five rivers of the Punjab, — the Sutlej, the Ravi, the Chenab, the Jhelum, and the Indus, besides the Byas which unites with the Sutlej. The valley of Kashmir is the upper part of the basin of the Jhelum.

The population of the whole of the mountain districts west of Nepal maintains to a great extent its Hindu type, though the Mahometan religion gradually becomes more prevalent as we approach the Indus, where it is found to have superseded Hinduism. In the more remote and elevated valleys an infusion of Tibetan race, religion, and language is found, diminishing as we pass to the west, but otherwise the dialects spoken are everywhere Prakrit, and closely allied to Hindi. As a rule the people are short in stature, muscular, as is common among mountaineers, fatter than the inhabitants of the plains, and in the western regions, where the Hindu or Aryan stock prevails, women of remarkable beauty are often seen. At the lower altitudes cotton clothing is usual, at the greater elevations hempen and woollen materials prevail, but an utter disregard of personal cleanliness is universal. Grease is frequent in both sexes, and cretinism seems to occur much in the European form.

The eastern ranges are wetter, the climate generally warmer and more equable, and the vegetation more rank and of a more tropical character, the mountains are more copiously covered with forest, and the extent of cultivation is less, and the population probably less also. To the west, with a drier atmosphere and greater variations of temperature, the climate above 5000 or 6000 feet becomes more like that of southern Europe, and the main features of the scenery become more conspicuously akin to those of European mountains. On the east the customs of the people differ little from those of the neighbouring Tibetan or semi-Tibetan provinces. On the west there is no great distinction between the people of the hills and of the plains in their customs, agriculture, or other occupations.

The summit of the table land from the borders of China Tibet to the 75th meridian, where the Indus suddenly turns off to the south, is comprised in Tibet, or as it is called in the language of its inhabitants "Dod" or "Bodjal." The latter word being equivalent to "Dod land." Of the eastern half of Tibet very little is known, and that little chiefly relates to the most southern portion which borders on the Himalayas, and the most eastern which abuts on China. The table-land here has its greatest development, and is perhaps as much as 500 miles from north to south. At its north-western end its breadth is reduced to something under 200 miles. The physical features of Tibet, from its great elevation, are so peculiar, and it is so cut off by nature from communication with its neighbours, that it is not surprising to find in it a distinct race with a language of their own, and habits widely different from the surrounding nations. The extreme cold and drought make Tibet essentially poor, and the character of its inhabitants approaches that of the denizens of the Arctic regions, who live under somewhat similar physical conditions. The people are broadly built, with a strongly marked Mongolian physiognomy, dark hair, little or no beard, oblique eyes, and prominent cheek bones. In the warmer valleys they are mainly agricultural, and live in houses, in the higher regions they are shepherds, living in tents, thinly scattered over a large area. They are clothed in woollens or sheep skins. The practice of polyandry prevails, a woman marrying a whole family of brothers. The government at Lhasa is nominally administered by the Tibetans themselves, but in reality is altogether under the control of a Chinese resident. The authority of the Lhasan Government extends to about 78° E long, west of this as far as the Indus, the country was conquered some forty years ago by the sovereign of Kashmir and remains under him. In the most western provinces of Tibet, called "Balti," the Buddhist religion ceases to prevail, the population is exclusively Mahometan, and that religion only is known beyond the Indus.

To the west of Tibet the mountains are prolonged to the 70th meridian at an elevation not greatly less than that which prevails eastward, and the table-land there ends in the region known as Pamir, which has all the characteristics of the higher parts of Tibet. Beyond this we pass into Turkistan and reach the limits by which the scope of the present article is restricted.

The difficulty of accomplishing with any approach to success such a task as that of giving a sufficient account of the chief physical and other characteristics of mountains like the Himalayas is much diminished by the remarkable uniformity in many points of structure and other important particulars, which prevails along the whole length of the chain. The perception of such general characteristics among mountains so vast is, indeed, too often overlooked and obscured by the magnitude of their parts, the multitude of their details, and the variety of their forms, yet when the idea of the subordination of all these elements to common laws has once been duly conceived, it obtains constantly growing confirmation from what at first only produced impressions of hopeless confusion.

The great plain of northern India stretches with an almost unbroken surface along the foot of the Himalayas from the upper Indus to the head of the delta of the Ganges, and thence has a narrow prolongation along the Brahmaputra up the valley of Assam. Including its extensions to the sea, along the Indus on the west, and along the Ganges on the east, its area is about 500,000 square miles. It nowhere rises to more than 1000 feet above the sea-level, and to the unassisted eye it appears a perfectly dead flat. That part of the plain which lies along the foot of the mountains, and more particularly the central and eastern portion, is well watered, being intersected by the numerous streams

Plains

that flow from the mountains, and under the full influence of the postglacial rains, and it composes the best cultivated, the richest, the most populous, and most civilized districts of India

The snow peaks of the Himalaya are, under favourable conditions, visible from the plains at a distance of about 200 miles. It is not, however, till the traveller is within 30 or 40 miles of the foot of the mountains that the outlines of the great peaks become well defined and their grandeur appreciable. At about the same distance, too, the low or ranges begin for the first time to attract attention. At about 40 or 55 miles from the outer hills the cultivation of the plain commonly becomes less complete, and the villages more sparse, an open grey tract is entered, often traversed by shallow, sluggish streams, along which are formed moraines, or ridges of glacial rocks and gravels, frequently occupying very large areas. This tract is known as the "Tatai," or "Tairai." Where most strongly developed it has a width of 10 or 15 miles, but its existence is manifestly greatly dependent on the local conditions of drainage and of rainfall, and to the west of the point where the Ganges leaves the mountains the Tatai is not formed. It has been erroneously described as a depression along the foot of the mountains, but there is no foundation for such a view, and the causes that lead to the formation are not far to seek.

To explain these it is necessary to take a further step towards the mountains. Just as the Tatai somewhat suddenly appears along a certain definite line, so it suddenly ceases, and is replaced by a band of forest of about equal breadth, known as the "Bhabar." This tract is almost waterless, and the soil is seen to be chiefly sand or shingle, more or less filled with boulders. The streams that issue from the outer hills on entering the Bhabar are for the most part rapidly absorbed, and finally disappear in their sandy or shingle beds, the water they pour into the soil being again discharged along the outer and lower border of the tract, and collecting once more in the streams which characterize the Tatai.

The Bhabar and Tatai slope continuously from the foot of the mountains to the cultivated plain. The inclination is so uniform as to be hardly perceptible, but becomes gradually less as the distance from the mountains becomes greater. Observation leads us to suppose that the upper part of this tract, lying along the foot of the outer hills, is composed of coarser material, and the lower part, which comes into view at a greater distance, of a finer and less permeable soil, and that, the latter having a smaller inclination and extending further than the former, the water absorbed by the upper beds will naturally be brought to the surface at their termination, where the finer materials forming clayey strata make their appearance. That the swampy Tatai is not developed in the western part of the range is doubtless due to the smaller rainfall in that region, while its more marked occurrence to the east of the Ganges at irregular intervals arises from the local peculiarities of the surface drainage, which at some places is carried off directly into the larger rivers without check, and in others is forced to follow a line nearly parallel to that of the mountains for considerable distances, through a tract from which there is no free escape for the water, and which, thus becoming water-logged and covered with a rank development of vegetation, acquires its peculiarities, among which has to be reckoned a climate in which ferms of a deadly character are frequently induced, rendering its permanent occupation and cultivation difficult or impossible.

The transition from the plains to the mountains is sudden and well-defined along a line that is almost continuous. The ranges to which geologists have given the name of

"Swakile," and "sub Himalayan," rise abruptly, and with out any intermediate undulating ground from the apparently level surface of the plain. These hills, which from recent geological investigation we learn to be formed of deposits of various periods of the Tertiary epoch, attain elevations from a few hundred to 3000 or 4000 feet. The dip of the strata composing them is usually at a low angle towards the mass of the mountains, so that they present a steep face to the plains, while a comparatively easy declivity slopes inward, and frequently, by meeting a corresponding but longer and more gradual talus descending from the foot of the internal line of mountains, forms a shallow narrow valley which runs generally parallel to the outer range.

These valleys, which are very characteristic of the outer border of the mountains, have by some writers been erroneously confounded with the Tatai. They are termed "Dun" in the western regions, in Nepal they are known by the name of "Mar." Their floors consist of deposits of gravel and boulders, having a maximum elevation of about 2000 or 2500 feet above the sea. Their continuity is broken at intervals by low, transverse, waterless lines, from which the drainage is thrown off along their length. At intervals these valleys are entirely wanting, and the outer hills which form them elsewhere are undistinguishable from the general mass of mountain within, except through the aid of their geological character. From the considerable elevation of the duns above the plains, down to the level of which the streams which drain them descend in a very short distance, the unconsolidated strata which form the floors of these valleys are often deeply cut into by the watercourses, and present a surface worn into terraces descending in steps of various heights. These conditions lead to a peculiarity which characterizes large parts of the duns, the almost complete impossibility of getting water from wells, due no doubt to the thorough denudation of the subsoil.

The sub Himalayan ranges have a well-defined distinct geographical existence along the greater part of the chain, and their geological continuity is established where no valley is formed between them and the inner ranges, and where they cannot be otherwise distinguished from the general mass of mountains. To the west of the Sutlej river these ranges and the valleys connected with them have an unusual development, the width over which they extend increasing from 10 or 15 miles to as much as 50 miles, with a series of two or three dún-like valleys one within another. West of the river Jhelum, again, the aspect of the outer Himalaya is entirely modified by a small plateau, which is formed to the north of the line of elevation known as the Salt range, and extends to the Indus. Its general surface lies at about 1000 feet above the general level of the plain, having a maximum elevation of about 1800 feet, and being remarkable for the extraordinary manner in which it is broken up by ravines, the number, gigantic dimensions, and intricacy of which are alike perplexing and astonishing—the extremely dry climate leading to an almost total want of vegetation, and the absence of any such concealment exhibiting a picture of confusion and desolation not often seen.

The ranges which lie immediately within the external band of the Swakile, or sub-Himalayan, rise abruptly above the rest of it to much greater elevations, and constitute the first masses which in such a region we can with propriety dignify with the name of mountains. Their ordinary elevation is about 7000 feet, and the highest summits on them reach 8000

or 9000 feet above the sea. It is on them that sanitary stations have been established for the convenience of the European residents in the neighboring provinces of India, as affording the nearest sites to the plains at which a temperate climate can be reached. These ranges cover a breadth of about 60 or 70 miles, within which the magnitude of the mountains does not vary greatly, their crests rarely going above 10,000 feet or falling below 5000 feet. Beyond this again another great change is observed, and the mountains rise rapidly and attain those surpassing heights which place the snow-clad summits of the Himalaya in the foremost rank of all the mountains of the earth.

Chute
to west
of basin

A remarkable deviation from the normal character of this zone of the mountains is observed to the west of the Sutley, where, combined with the exceptional extension of the sub Himalayan ranges already noticed, is found what may perhaps be best described as an outlier of the great central axis of snowy mountains. With a marked change in respect to elevation, as well as in respect to its mineral constituents, the range locally known as the "Dhianadhi," or White Mountain, rises directly from the dun of Kangra, the elevation of which is about 2500 feet, into the regions of perpetual snow, its highest points reaching an elevation of 16,000 to 17,000 feet. The same features are prolonged still further to the west beyond the Ravi, and this line of elevation forms the great snow-clad range that shuts in the valley of Kashmir on the south, there known as the Pir panjal, the general elevation of which is from 14,000 to 15,000 feet, and the passes over it not lower than 10,000 feet.

Snowy
ranges
seen in
position

With this exception the ranges covered with perpetual snow as a first met with on the southern slope of the great Indo Tibetan table-land, along a line between 80 and 90 miles south of the foot of the outer mountains, and 20 or 30 miles south of the Indian watershed, and from this line northward snowy peaks abound everywhere over the summit of the table-land. The highest yet measured are near the Indian watershed, but as it is only in this region of the western Himalaya, and in northern Ladák, that any complete survey has been made, it is necessary to be cautious in making statements as to absolute maximum elevation, for the known in these mountains still bears far too small a proportion to the unknown to afford sufficient ground for safe speculation on such a subject.

Line of
highest
peaks

On the Himalayan slope the loftiest peaks are usually met on the first ranges that enter the limits of perpetual snow, advanced some 20 or 30 miles south of the Indian watershed, and not on a continuous ridge, but grouped in masses separated from one another by deep depressions, through which is discharged the drainage of the tract lying between them and the watershed.

Height
of peaks

The highest known peak in the Himalaya, and indeed in the world, is that in Nepal known as Mount Everest, which rises to 29,002 feet. Kinchinjunga, in Sikim, on the east, reaches 28,156 feet, and another peak more recently measured, in the extreme west, reaches 28,278 feet. Dhawalagiri, in Nepal, is stated to be 26,826 feet, and Nanda-devi, in Kumaon, to be 26,700 feet above the sea. But many other points have been measured exceeding 25,000 feet in elevation, two of which are to the north of Kumaon, and the enumeration of all known peaks over 20,000 feet would be wearisome. These statements have reference to the particular zone along the Indian watershed above described, beyond which, as was before said, few measurements have been made (excepting in Ladák), but there is every reason to believe, from such scanty facts as are available for forming an opinion, that mountains rising considerably above 20,000 feet are of frequent occurrence throughout Tibet.

To give a more precise idea of the character of the snowy Num zone, it will be worth while to state somewhat in detail the best of distribution of the great peaks which lie between the 78th and 81st meridians, in the provinces of Kumaon and Garhwal, which have been far better surveyed than any other part of the range. On a line of something less than 160 miles in length are found six great snowy groups, with five great rivers passing between them—(1) on the east is the cluster of Api in Nepal, with a peak of 22,700 feet, (2) Yimyang, between the Dama river and the Kali, rising to 21,300 feet, (3) the Panchchuli group, between this Dama river and the Gori, with a maximum of 22,700 feet, (4) the great compound mass which lies between the Gori and the Dhaol rivers, consisting of Nanda-devi, Nanda-kot, Dunaqur, and Thail, the first reaching 25,700 feet, the second 22,600 feet, the third 23,300 feet, and the last, having a length of more than 10 miles, no part of which is under 20,000 feet, its central point reaching 28,400 feet above the sea, (5) the peaks between the Dhaol and Vishnuganga rivers, three of which lie between 22,800 and 23,600 feet, (6) the great group of Badarnath, Kedarnath, and Gangotri, between the Alaknanda and Bhagirathi, the chief feeders of the Ganges, the first mass rising to 22,400 feet and the second to 23,900 feet, while the third has five points varying in height between these. All these masses are connected with the main watershed by ridges more or less covered with perpetual snow. The first range has been measured two other peaks rising above 25,000 feet, several others reaching 23,000 feet, and many more between 19,000 and 20,000 feet. There is no reason for thinking that this gives an exaggerated idea of the vast scale on which these mountains are developed. There can be little doubt that as precise knowledge is advanced the number of peaks between 25,000 and 30,000 feet will be found to be very much extended, nor will it be surprising if points are eventually discovered exceeding 30,000 feet in altitude.

The average elevation of the crest of the Indian watershed, between the points where the Indus and Bhakmanputra cross it, a distance of some 1900 miles, most probably exceeds 18,000 feet. At a comparatively few points only its continuity is broken, and it allows the passage of rivers that rise on its northern flank, but at all other parts its summit must be crossed to enter Tibet from the south. The passes over it, in ordinary use for men and animals, are frequently more than 18,000 feet above the sea, and except where it is broken through as just mentioned, one point only is believed to exist at which it can be surmounted under 10,400 feet. This pass, which leads directly from Kashmir into the Tibetan district of Diás, is only 11,300 feet, and is quite anomalous, such a depression elsewhere would have been sufficiently deep to open a passage for the drainage of the table-land, but the great depth of the valley further north, in which the Indus flows, here gives the waters a more favourable escape in that direction.

The valleys which traverse the mountains between the Valley plains and the great watershed are for the most part little more than gigantic ravines, at the bottom of which flows the river each contains, in a very contracted bed which at rare intervals opens out into a narrow alluvial flat capable of cultivation. The level of the river beds is necessarily very various. Valleys only 2000 or 3000 feet above the sea are often opened up into the very heart of the mountains, and early with them the heat and vegetation of the tropics among ranges the summits of which are capped with eternal snow. In tracing up the larger streams it is usually found that on arriving within 10 miles of the line of the great peaks the rivers are flowing at an elevation of little more than 4000 or 5000 feet, but on crossing that line the acclivity suddenly and rapidly increases, and the

river beds in a very few miles are found to be at an altitude of 9000 or 10,000 feet, indicating that the sudden increase to the height of the mountains along this line is not confined to the peaks alone, but consists of a general elevation of the whole surface. Having once crossed the line of great peaks, the inclination of the valleys again becomes much less, and they thus continue for some miles, those that are fed from the larger glaciers frequently emerging from the ice at a level no more than 12,000 feet above the sea in the western mountains, 1000 or 2000 feet higher on the east.

Then slope

The slope of the larger Himalayan rivers may be estimated to range from 20 feet per mile near the plains to between 100 and 200 feet per mile where they approach the snowy mountains. In these passes through these high mountainous masses, to as much as 700 or 800 feet in the mile, but to the north it again reduced to 150 or 300 feet. Like all Indian rivers, they vary greatly in volume at different seasons of the year, and among the higher mountains are liable to special fluctuations from the more or less rapid melting of the snow from which they are fed. In the summer their waters increase and decrease with the varying temperature of the day or power of the sun, and in the winter they contract to a small fraction of their summer volume as the permanent frosts set in. In the lower parts of their courses the rivers commonly present an alternation of sparkling rapids with long reaches of deep, clear, tranquil water, which the action of the current often hardly visible, as we ascend, the rapids become by

degrees more frequent and more impetuous, till in passing among the snowy mountains we find only the most furious torrents, pouring their turbid glacier waters over boulders of gigantic dimensions among which they are at times almost lost to view, and filling the valleys with their incessant roar.

The valleys of Kashmir and Kathmandu, by their exceptionally large extent and comparatively level character, offer such remarkable deviations from the normal character of Himalayan valleys as to require some comment. But the differences are after all rather in degree than in kind, and it would not be difficult to find somewhat similar areas, though on a much smaller scale of development. In Kashmir, too, is found one of the very few lakes which occur in the Himalaya. The almost complete absence of such collections of water is among the circumstances which serve to give a special character to the scenery of the Himalaya, and to distinguish it from that of European mountains.

On crossing the Indian watershed into Tibet, the general character of the country completely changes. The summit of the table land, though deeply corrugated with valleys and mountains in detail, is in its general effect laid out horizontally at a mean height little inferior to that of the watershed itself. The valleys of central Tibet are commonly long, flat, and open, of no great breadth, perhaps 1 to 3 miles, with a bottom of alluvial soil laid out nearly horizontally, from which the mountains rise abruptly on either side. The plateau of Gugu, immediately to the north of Kumaon,

FIG. 1.—Sketch of the Alps and of the Himalayas on the same scale.

the average elevation of which is not less than 12,500 feet above the sea, and at the extremity of which lie the two lakes of Rakis tal and Manasarovar, the waters of which are also nearly at that level, is a remarkable expansion of the ordinary Tibetan valley, and calls for special notice. It varies in breadth from 15 to 60 miles, and its extreme length is 120 miles, lying along the upper course of the Satlej, which runs throughout at the bottom of a stupendous ravine furrowed out of the alluvial matter of which the plateau is formed, to a depth of 2000 or 3000 feet. Into this run, across the western part of the plain, numerous other smaller ravines in every gradation of size, often for miles together as even and straight as a railway cutting, and so extraordinary is their magnitude in some cases that, in his account of a journey across the plateau, Moorcroft, a traveller of great accuracy in general, describes these slopes as those of mountains.

Tibetan rivers and lakes

The main valleys are everywhere remarkable for their gentle slope, and in the central parts of the table-land the inclination at length frequently becomes so small as to give rise to the accumulation of the drainage in lakes, invariably salt when there is no efflux, and as invariably fresh when there is. The upper Indus has a slope as little as 3 feet per mile. Further to the west, as it approaches its great bend to the south, the inclination becomes greater, averaging about 24 feet per mile, and the width of its valley floor is reduced. It descends to a level of little above 4000 feet before it finally leaves Tibet.

It may aid in conveying a clear conception of the magnitude of these Himalayan masses, to compare them with the Swiss Alps, which will be familiar to many English readers. The above diagram represents on the same scale sections of the Alps and of the Himalaya, the curved line from which the latter are shown to rise representing the curvature of the earth. The Alps, measured across from the Lake of Thun to the plains of Lombardy, have a width of about 75 miles, the Tibetan-Himalayan mountains on a line drawn through Simla being about 400 miles across. To complete the comparison a few further explanations may be offered. The range that has already been noticed as the Dhauladhar, which rises from the Kangra d6n, if measured in breadth from Kangra to the upper Ravi, and in length between that river and the Ravi in Kullu, is about equal to the whole of the Bernese Alps comprised between Atdorf and Martigny in length, and laterally between lines drawn along the Rhone and Reuss on one side, and through the Lakes of Lucerne and Thun to the Lake of Geneva at Vevey on the other. The area covered in both cases is rather less than 100 miles in length by 90 or 25 in breadth, the highest peaks being in the Alps the Furstenthorn, 14,100 feet, and in the Dhauladhar a point 17,100 feet above the sea. The prolongation of the Himalayan ridge just spoken of, which bounds Kashmir on the south, known as the Pir-pangal, would in like manner compare with the Pennine Alps and their continuation as far as St Gothard. Here the peak

of Mont Blanc, 15,750 feet, slightly exceeds the highest point of the Pir-pangal, which is but little over 15,600 feet, though, with this single exception, the Kashmir range certainly much exceeds in general mass that of the portion of the Alps compared with it. To obliterate these two ranges from the Himalaya would make no very sensible incision on it, though they surpass in bulk the whole of the Swiss Alps, and it is no exaggeration to say that, along the entire range of the Himalaya, valleys are to be found among the higher mountains into which the whole Alps might be cast without producing any result that would be discernible at a distance of ten or fifteen miles. And it is important to bear in mind the relations of magnitude, for the terms at our disposal in the description of mountains are so limited that it is necessary to employ the words chain, range, ridge, spurs, &c, rather with reference to relative than to absolute importance, so that the scale of our nomenclature changes with the extent and altitude of the mountains of which we speak.

An examination of the maps of the Himalaya indicates that throughout their whole extent a constant tendency is discernible for the rivers to flow either parallel to the general direction of the part of the chain through which they run, or perpendicular to it,—many or perhaps most of them combining both tendencies, and running first in the one direction and then in the other. The conclusion is hence suggested that the system of surface drainage is determined by a series of longitudinal and transverse lines of rupture along and across the mountains. The study of the rivers and mountains themselves confirms this view. In many cases an apparent diagonal direction is found to be really due to a succession of short abrupt bends, though no doubt the rivers at times actually take an oblique course across the mountains. Frequently, too, where a river changes from a longitudinal to a transverse direction, another longitudinal stream meeting the first flows down from an exactly opposite direction. The same disposition is otherwise often exhibited by the occurrence of both transverse and longitudinal lines of drainage, or valleys, straining in opposite directions from the same point on the main range, while a depression occurs in the ridge at the point whence such valleys take their departure.

As the rivers and ridges that separate them must be laid out on the same general plan, it is natural to find in those last the same tendency to follow lines perpendicular, or parallel, to the general direction of the chain. There is no part of the mountains in which these peculiarities may not be traced, the longitudinal character prevailing on the summit of the table-land, and the transverse being dominant on the Himalayan slope. By the combination of these tendencies the rivers flow to the plains along a line generally oblique to the component parts of their actual course, and the watershed ridges that separate them follow corresponding directions. But such watershed lines rarely have any true structural continuity, however strongly they may be marked on our maps, and great caution must be exercised in inferring physical relations among such features of the mountains without obtaining some knowledge of their geological structure.

Considering the vast extent of these mountains, and the material and political difficulties in the way of the traveller who visits them, it is not surprising that the knowledge of their geological structure is still very imperfect. From causes which are not very obvious, important parts of the deposits of which they consist have till now been almost entirely unexplored, and the remains by which their age can be determined, the visits of qualified geologists to the more remote parts of the chain have been very rare, and it is only within the last few months that any connected memoir on the subject has been published. Much that has been

written on it is of too speculative a nature to find place in such an account as the present, and all that can be attempted is a brief outline of the main conclusions that seem established.

Of the great Indian plain nothing very definite can be said. It is an alluvial deposit of sandy clay, on the surface of which nothing in the shape of a public can be found excepting in the immediate vicinity of the hills that rise from it. In one place alone, in the north-west, on the Jumna river, have fossil remains been found imbedded in it, at some depth below the surface. They belonged to terrestrial mammals, with fish and crocodiles, which seem to be of the post Tertiary epoch. A few borings have been made to depths of some hundreds of feet, but they throw no great light on the subject of the origin of the plain. There is no direct evidence either for or against its having been laid out by the sea, on the one side it seems difficult to understand how so even a surface could have been produced otherwise than under the sea, while on the other there is a complete want of marine remains both in the alluvium itself and in the most recent deposits which form the hills that rise from it. It seems to be admitted that some parts of the alluvial plain of the Indus have been submerged, and in any case, if it was produced by river action, it must have been by rivers having a very small inclination, and in a delta, or at a low elevation.

The outermost ranges of the sub-Himalaya are also geologically the most recent. They are composed of grey micaceous sandstones, generally very soft and often quite unconsolidated, with beds of red and blue clays and marls interspersed, and boulder and gravel beds, at times hardly to be distinguished from those formed in the existing rivers, and often cemented by carbonate of lime into conglomerates. Though these formations are most strongly developed to the west, they have been observed in Nepal and also in Bhootia. It is from the ranges in the vicinity of the Jumna river that the characteristic Siwalik fossils have chiefly been obtained. They consist of numerous species of mammals and reptiles, with a few fish, birds, and molluscs,—all, however, remains of land or fresh-water animals, with no certain trace of marine creatures. Lagune occurs in thin isolated beds in small quantities. It had been commonly supposed that the Siwalik fauna was of Miocene age. The latest views rather point to its being Pliocene. Sixteen genera among the fossil remains have not been found in any beds older than Pliocene, and of the many genera which continue to the present time, some of the forms preserved in these fossils are remarkably similar to existing species, all of which indicates a closer relation to the more recent than to the older Tertiaries.

In close juxtaposition with this outermost band, but constituting a distinct geological zone, is a series that has not been very clearly established, is an older series of beds, the lowest of which is nummulitic and of the oldest Tertiary epoch. The fossils found in these beds are as markedly marine as those of the other series are terrestrial. The junction of the new with this more ancient series is concealed by disturbances, and the former has not been found overlying the latter, but only abutting upon it. This older section of the Tertiary beds of the sub-Himalaya has only been properly made out to the west of the Jumna, though it is likely that it is also represented in the central and eastern parts of the chain by certain sandstones which occur there at the foot of the higher mountains. It may be surmised also that the nummulitic beds of these ranges are connected on the one side with those which are found to the west of the Indus extending to Sindh, and on the other with the nummulitic rocks of the hills south of Assam.

chain

passing from these outer and lower ranges to those higher mountains, which extend to the line of snowy peaks. On the west of the chain the first of these ranges consists of argillaceous shales, and schists, gneiss and limestone, intersected by several lines of igneous action, and all devoid of fossil remains. True slates also occur. The stratification is everywhere well marked, the dip being usually towards the interior of the chain at an angle of from 10° to 30°. Portions of the mountains are found in which the dip is quite reversed, or towards the plains, a result no doubt of absolute rupture and partial dislocation. The lines of igneous action follow generally the line of strike, the type of the rock being greenstone, and conglomerates or breccias, being often associated with it.

Fossiliferous
ages and
relations

How far these beds extend to the eastward is somewhat in doubt. Suggestions have been made that they are the representatives of the Silurian or other fossiliferous beds found to the north of the great snowy mountains, but the evidence for this is hardly conclusive. The occurrence at the foot of the mountains in Sikim and Bhutan of a deposit containing fossil coal plants, which are apparently identical with those of the Bengali coal field, renders it probable that the rocks thence are of the age of that coal, that is to say, of the lower Tria, a conclusion which somewhat serves to corroborate the speculation as to the age of the western beds just referred to.

Lines of
gneiss
and
other
igneous
rock

In certain parts of this outer region of the mountains granite also occurs, accompanied by gneiss and mica schist, the latter often abounding in garnets. In mineralogical character this granite and its accompanying schists differ greatly from those of the great peaks, which are also formed of granite and schists, this has suggested a possible difference of age, and it remains uncertain whether any or what connexion exists between them.

The
snowy
mountain
range

As we approach the line of great peaks the rocks pass into highly crystalline gneiss or mica schist, and another more continuous line of granite intrusion occurs, divided into several branches, but distributed generally on the line of strike, that is, along the principal direction of the chain itself. It is chiefly in veins, though it expands at times into masses of considerable size, and more rarely into outbursts large enough to constitute whole mountains. The general dip of the strata continues throughout this area to be directed inwards, its angle being increased to as much as 45°, though seldom to more than that. Beds of highly crystalline limestone, some pure, and some not easily distinguished from the gneiss or mica schist among which they occur, are common along a band following the direction of the strike. The vein granite is usually large grained, homoblastic at times replaces the mica, the felspar is invariably white, and crystals of schist and kyanite are frequently seen in it.

Great
peaks

The great peaks are, with few exceptions, composed of schistose rock, though granite veins may be seen in the mountain faces to very great elevations, one of these exceptions is the great peak of Kāmet in Kumaon, which rises to about 25,000 feet in what appears to be a mass of grey granite.

Fossil
traces
of the
Silurian
and
Devonian

Passing to the north of the line of great peaks the metamorphosed schists are suddenly replaced by slates and limestones, which are in many places highly fossiliferous, exhibiting what appears to constitute in the aggregate a fairly continuous series from the Lower Silurian to the Carboniferous formations, though the complete sequence has not been observed in any one locality. The western region of the Himalaya alone has been sufficiently explored to admit of any positive statements, but the indications gathered from such imperfect accounts and other data as exist relative to the eastern parts of the mountains leave little doubt that the change observed in the west on approaching and enter-

ing Tibet holds good on the east also, and that the general physical features of the whole tract are much alike, though doubtless with many differences in detail.

The fossiliferous strata of western Tibet are continued, Plateau though perhaps, with some breaks, to the Tertiary period. In certain localities mammothlike rocks, probably Eocene, have been observed, and from the great alluvial deposit which forms the plain of Gogā, already noticed, the remains of mammoth, apparently of Siwalik age, have also been obtained. Among these were bones of the elephant and the rhinoceros, the existence of which, in the present condition of these regions, would be wholly impossible, so that there is no room to doubt that these deposits have been raised from a comparatively low level to their existing great elevation of upwards of 15,000 feet, since they were laid out. As in the case of the plain of India, we here, too, have no complete proof of the origin of these great nearly horizontal deposits, but it seems clear from the materials of which they are formed, that they must have been laid out by water, either by the sea of some great inland lake. They are largely composed of boulder deposits, and large boulders are strewn over the surface imbedded in the ground in a manner that seems only explicable as the result of the action of a considerable body of water.

Several lines of granite and eruptive rock occur in Eastern western Tibet, of which all that need here be said is that rocks in their present all to be older than the Tertiary alluvium, but Tibet some of them are possibly contemporaneous with the numerous and older formations.

The general conclusion that may be drawn from the facts of structure thus briefly indicated is that the elevation of the Himalaya to its present great height is of comparatively recent occurrence. An area of land must have existed where the main line of snowy peaks now stands, which has not been submerged since the Palaeozoic period, and which then had its northern boundary somewhere along what has been termed the Indian watershed. Evidence of a similar ancient sea on the south also exists, but in a less definite shape, and whether it was united with the northern sea or not is still a matter of conjecture, though the distinctive character of the fossils rather indicates that there was no direct union. The possible connexion of this ancient Himalayan land area with the pre-Tertiary land of the peninsula of India is also only a matter for speculation.

There is further reason to infer that the existence of the great line of peaks is rather due to some previous line of elevation on the ancient land, which has continued to retain its relative supereminence while the whole area has been raised, rather than to any special line of energy of upheaval of recent date, and that the fundamental features of its former configuration of surface in mountain and valley have been preserved throughout. There is evidence for the conclusion that the chief rivers of the pre-Tertiary land issued from the mountains where the present main streams are found, and the embryo Himalaya may have been of such moderate height as to have permitted the passage across it of the Siwalik mammals, the remains of which appear both on the border of the Indian plain and in Tibet. It is after the middle Tertiary epoch that the principal elevation of these mountains must have taken place, and about the same time also took place the movements which raised the table lands of Afghanistan and Persia, and gave southern Asia its existing outline.

The best answer that can be given to an inquiry as to how changes of level could have arisen, such as those which are observed in the Himalaya, is that they should be regarded as due rather to secondary actions consequent upon the general contraction of the cooling terrestrial mass of sphere than to direct elevating forces, for which no action

Known origin can be assigned. The contraction of the cooling but now solid crust of the earth must have set up great horizontal strains, partly of tension and partly of compression, which would necessarily have been followed by rupture or crushing along lines of least resistance, and the movements on such lines are marked by the great mountain ranges that traverse the surface. A dislocation of the solid crust of the earth once having taken place, it would probably continue to be a line of least resistance ever after, and a succession of movements during past geological periods may thus be reasonably expected along such lines. Somewhat in proportion as the disturbing forces are intense, and the thickness of the crust on which they act is great, will be the tendency for the lines of rupture to be continuous for a considerable distance, and as the disturbed area is extended in its dimensions, the probability will increase of a repetition of a series of similar dislocations on lines approximately parallel to, or at right angles to, one another, and to the line on which the greatest compression and consequent tension take place. In a disturbed area, one transverse dimension of which is sensibly greater than the rest, the longitudinal ruptures will predominate in the interior and the transverse towards the borders. Almost all mountains give indications of having been shaped by forces thus related, and to the action of such forces may the main characteristics of the structure of the Himalaya, and the arrangement of its ridges and valleys, be attributed. Whatever may be the power of rivers in general as instruments of erosion, and whatever effect the Himalayan rivers have had in removing the fragments of the rocks over and among which they took their course, it is hardly possible to doubt that their main dissection were determined by the anterior lines of dislocation which opened up hollows down which they could flow, and which must invariably have been accompanied by a destructive and crushing action on the rocks along them, which has enabled the waters the more readily to sweep away the obstacles in their path. The parallelism of many of the great Tibetan and Himalayan rivers for hundreds of miles together, amid such mountains, seems wholly inexplicable in any other manner.

Micro-
logy
effects of
mount
rains on
atmo-
sphere

Although the loftiest mountains when compared to the earth's diameter are insignificant in their dimensions, and the irregularities of the surface would hardly be perceptible on any sphere, however large, that could be made to represent the earth, yet in relation to the depth of the atmosphere even moderate elevations become of great importance, and such heights as those reached by the Himalaya introduce modifications of climate in ascending over its slopes that are not surpassed by those observed in moving from the equator to the poles. One half of the total mass of the atmosphere and three-fourths of the water suspended in it in the form of vapour lie below the average elevation of the Himalaya, and of the residue one half of the air and virtually almost all the vapour come within the influence of the highest peaks.

Baro-
metric
pressure
and
vapour

The general changes of pressure of the atmosphere indicated by the barometer extend in a modified but well-marked manner to the greatest elevations to which observation has been carried, and the annual and diurnal oscillations are not less regular in Tibet than in the plains of India, though somewhat reduced in amount. With the increase of elevation the diminution of the quantity of vapour held in suspension is very marked, and at the greatest heights reached there is found not more than one-sixth or one-seventh part of that observed at the foot of the mountains, and the proportion is sometimes as low as a tenth, or less. As is well known, the maximum quantity of water that can be suspended in the air in a state of vapour depends on the temperature of the air, and observa-

tion has established that the actual quantity at all elevations is approximately proportional to this maximum, and is thus determined by the temperature, which in turn is regulated by the elevation. The theoretical view once held that watery vapour was distributed in the atmosphere in accordance with the laws of pressure of elastic fluids is manifestly inconsistent with observed facts, which indicate that the diffusion of vapour is powerfully obstructed by the air particles, and that it by no means behaves as an independent elastic fluid, but rather as though it were merely mixed up with or entangled among the air particles.

The great elevations to which the Himalaya ascends, and the broad zone which it covers in respect to latitude, ^{Temper-} ^{ature of} ^{the air} and its varying distance from the sea necessarily lead to correspondingly great variations of climate in its different parts, including the temperature and the degree of humidity in the atmosphere, and the amount of rainfall. The general position of the whole tract between the 25th and 35th degrees of north latitude renders it subject to high summer temperatures. The heat of the great plain of northern India is not surpassed at any other part of the earth, the air temperature rising in the hottest months to more than 110° Fahr., the fall of temperature in the winter is considerable, the thermometer reading at times to the freezing point, or even a little below it, the mean temperature varies from 78° Fahr. in the east or southern portion to 73° in the west or north. On the mountains every altitude has its corresponding temperature, an elevation of 1000 feet producing a fall of about 3½°, or 1° Fahr. to 300 feet. The mean winter temperature at 7000 feet is about 44° Fahr., with a mean minimum of 32° Fahr., and the summer mean about 65° Fahr. At 9000 feet the mean temperature of the coldest month is 32° Fahr., at 12,000 feet the thermometer ceases to fall below freezing point from the end of May to the middle of October, and at 15,000 feet it is seldom above that point at the coldest part of the day in the height of summer. There seems to be less variation of temperature at equal altitudes on the mountains in passing from east to west than might have been expected from the greater winter cold of the western part of the plains. This is probably due to the greater relative humidity and heavier rainfall of the eastern regions, and the dense vegetation which covers them. These influences tend to keep down the day temperature on the eastern mountains, while the clearer skies and more open character of the west operate in the opposite direction. On the more woody and rainy mountains in the outer parts of the chain the mean summer temperature will be 60° at 10,000 or 11,000 feet, but it will still be as much as that up to 12,000 feet, or even to a greater elevation, in the bare and sunny valleys near the Indian watershed.

In Tibet the thermometrical conditions vary considerably from those of the Himalayan slope. At 12,000 feet the maximum temperature is perhaps 70° Fahr. and the absolute minimum 5° Fahr. The ordinary winter temperature is from 0° Fahr. to 30° Fahr., with a mean of the coldest month of 10°. The mean of the hottest month is about 60°, and of the year 35°. At 15,000 feet the frost is permanent from the end of October to the end of April, and the lakes are usually frozen over for nearly five months in the year. Between 15,000 and 18,000 feet the thermometer will fall below the freezing point every night of the year. At heights of 17,000 or 18,000 feet it rises considerably above that point in the summer months. From 13,000 to 19,000 feet it thaws only in the afternoons of July and August, and at 20,000 feet there is probably perpetual frost in the shade, though in the sun the air no doubt rises above the freezing point to much greater elevations.

Freezing
of rivers.

All the rivers in Ladakh are frozen over every winter down to 8000 feet, a phenomenon that has been nowhere seen in the Himalaya, the rivers that are accessible during winter being at too small an elevation to be so frozen, and the main streams probably everywhere too rapid.

Diurnal
and
other
effects
of
temper-
ature.

The diurnal range of temperature is directly dependent on the condition of the surface and the state of the sky. On all well wooded ranges it is very small, particularly in the cloudy and rainy months, when it will not exceed 5° or 6°. In the dry months of April or May, before the summer rains begin, and in the autumn when clear skies again prevail, the variation is greatest. In Tibet it is greatest in summer and least in winter, which is the most cloudy season. The annual variation follows a similar law, 20° being about the minimum mean monthly range on the wooded mountains, while in Tibet it amounts to as much as 30°.

Con-
parison
of
temper-
ature
in
western
parts
of
China.

The difference of temperature between ranges densely clad with forest and the Indian plains may be twice as much in April and May as in December or January, and the differences between the temperatures of a well-wooded hill top and an open valley below have been observed to vary as much as from 9° in the coldest to 24° in the hottest hour. Precisely the converse may be found to hold good in comparing greater altitudes in Tibet with lower in the Himalaya, where the humidity is greater.

General
relation
of
temper-
ature
to
the
rain.

It is generally true as we observe—(1) that the decrease of temperature with altitude is most rapid in summer, (2) that the annual range diminishes with elevation, and (3) that the diurnal range also diminishes with elevation. But the greater quantity of cloud and the more dense covering of forest between 9000 and 10,500 feet render comparisons between this zone and the more open and less cloudy regions above and below anomalous for reasons that will be apparent after the above remarks.

Rainfall
possibil-
ity, how
ruined.

The chief rainfall on the Himalaya, like that of India generally, occurs in the summer months between May and October, the remainder of the year being comparatively dry. The physical causes which give rise to the south-west monsoon, under which name is known the season of summer rain as well as the south-westerly winds which accompany it, have been sufficiently explained in the article on ASIA, to which the reader is referred for further details.

General
distri-
bution.

The fall of rain over the great plain of northern India gradually diminishes in quantity, and begins later, as we pass from east to west. At the same time the rain is heavier as we approach the Himalaya, and the greatest falls are measured on its outer ranges, but the quantity is again much diminished as we pass onward across the chain, and on arriving at the border of Tibet, behind the great line of snowy peaks, the rain falls in such small quantities as to be hardly susceptible of measurement.

Mon-
soon
winds
their
causes.

An important agent in distributing the rain which falls over the Himalaya, if indeed it be not the essential one, is found in the diurnal currents of wind which are established from the plains towards the mountains, and *vice versa*, blowing up the valleys towards the main watershed from about 8 A.M. to 3 P.M., and in the opposite direction during the corresponding hours of the night. These diurnal winds, which are a very striking phenomenon, and blow in the afternoon with great force along the Himalayan and the main watershed and the neighbouring parts of the plain of Tibet, are common to all mountains, and are no doubt due to the disturbances of the planes of equal atmospheric pressure in a direction transverse to the mountains, caused by the unequal diurnal expansion and contraction of the columns of air respectively over the plains and mountains, the former being obviously longer than the latter, so that the planes of equal pressure are lifted by expansion higher over the plains during the day, and depressed by contraction

during the night, thereby setting up currents to and from the highest region of the mountain, as these alternating actions take place.

The condensation of vapour from the ascending currents thus set up across the Himalaya from the Indian plain, and their gradual exhaustion by repeated precipitation, as they cross successive ranges, is manifested to the traveller on the face of the mountains themselves, by the changes observed in the vegetation on passing to leeward of any important range, and most especially the line of great snow peaks. In the rainy months in the higher parts of the chain the southern face of each ridge is clothed by the day upwind with a crest of cloud, which hangs upon it, the northern face being often left entirely free, thus showing how large a portion of the vapour is arrested, and showing also that it is only up the deeper gorges that a small supply of moisture finds its way to the Tibetan table land.

The yearly rainfall, which amounts to between 60 and 70 inches in the delta of the Ganges, is reduced to about 40 inches where that river issues from the mountains on the 78th meridian, and is no more than 30 inches near the foot of the mountains at the issue of the Indus. At Dargaling, at about 7000 feet on the east, on the outer border of the mountains, it amounts to about 120 inches, at Nami-tan, at about the same elevation and similarly situated in 70° E. long., it is about 90 inches, and further west it is still more reduced in quantity. In passing from the exterior to the interior of the chain the quantity greatly diminishes. In Kumaon, while in three months 40 inches was registered at Nami-tan on the outer range, only 19 inches fell at Almora, at 5600 feet, 30 miles further in. At Joshimath, 50 miles onward and close under great snowy peaks, at 6500 feet, 22 inches were measured in the same period, while at Niti, 11,500 feet behind the snowy peaks, the fall did not exceed 5½ inches. In a week of rainy weather, when 1½ inches fell at Joshimath, half an inch was measured at Niti, while beyond the Tibetan watershed during the same period the rain fell in a very faint drizzle which could not be measured at all. Similar facts might be quoted from the eastern mountains.

In the eastern Himalaya, the ordinary winter limit of snow snow is 6000 feet, and it is rare for even 3 inches to remain as fall many days on the ground on a southern exposure at 7000 feet. In Kumaon, on the west, it is pretty certain that snow will fall every year at about 6500 feet, and at 5000 feet it will not fall one year out of ten, the lowest level to which sporadic snowfalls are known to descend is about 2500 feet, of which two or three instances have occurred in the present century. In Ladakh, at an elevation of a little above 1000 feet, snow occasionally falls, but very rarely. At Ld, in western Tibet, the results of two years' observations indicate that the depth of snow that falls is less than 2 feet, the heaviest continued fall measuring 8 inches and lasting three days, at an elevation of 12,500 feet. Depths of 3 feet have been measured on passes between 17,000 feet and 19,000 feet above the sea. On the Indian watershed the falls are much heavier, and even in September the passes are sometimes quite blocked by the falls which commonly occur after the equinox, and they are not usually open again till the middle of June.

It is now satisfactorily established that the snow line, or the level to which snow reaches in the course of the year, snow-never from 16,000 to 18,000 feet on the southern ex-poses of the Himalaya that carry perpetual snow, along all that part of the chain that lies between Sikim and the Indus. It is probably not till December that the snow begins to descend for the winter, though after September light falls occur which cover the higher mountains down to 12,000 feet, but these soon disappear. On the Indian

watershed the snow line is not lower than 18,500 feet, and on the summit of the table land it reaches a height of about 20,000 feet. On all the higher passes into Tibet the vegetation reaches to about 17,500 feet, and in August they may all be crossed in ordinary years, even up to 18,400 feet, without finding any snow upon them, and it is as impossible to find snow in the summer on the great plain of Gogé in western Tibet, at 15,500 feet above the sea, as on the plains of India.

There was at one time much discussion as to the true cause of the level of the snow line being higher in Tibet than on the outer ranges of the Himalayas. But the reason is obvious, namely, the greater quantity of snow that falls on the outer ranges. The snow line marks the limit beyond which some snow always remains unmelted, that is, the point where on the average of years the summer heat will destroy the winter's snow. The main element in determining such a point will evidently be the quantity of winter snow that falls, the summer heat being not very different over the whole area. That the fall of snow on the outer ranges is greater than it is nearer the watershed at the same elevation is beyond doubt, and the smaller quantity of snow is more evenly and earlier melted.

It was long affirmed that there were no true glaciers in the Himalayas, and ingenious arguments were adduced to account for their absence. But, in fact, they abound along all the higher ranges precisely in those countries under which they are found elsewhere, and all the phenomena observed elsewhere in connexion with them are reproduced in those mountains.

The level to which the Himalayan glaciers descend is very various, being greatly dependent on local conditions, principally the extent and elevation of the snow basins which feed them, and the slope and position of the mountain on which they are formed. A glacier formed on the southern face of the Himalayas may readily be in a position in which it might, with a length of 10 miles, descend from 18,000 feet to 11,500 feet. But in Tibet, or in the highest valleys, it might as readily happen that in 10 miles no lower level than 18,000 feet could be reached. With a larger snow basin on the south the greater waste in reaching the lower level might easily be compensated, while no conceivable supply would enable the Tibetan glaciers to reach 11,500 feet, to do which it must extend perhaps 100 miles. These considerations will sufficiently explain the fact that the glaciers on the outer slopes of the Himalayas descend much lower than is commonly the case in Tibet, or in the most elevated valleys near the watershed. The glaciers of Sikkim and the eastern mountains are believed not to reach a lower level than 13,500 or 14,000 feet. In Kumaon many of them descend to between 11,500 and 12,500 feet. In the higher valleys and Tibet 15,000 and 16,000 feet is the ordinary level at which they end, but there are exceptions which descend far lower. In Europe the glaciers descend between 3000 and 5000 feet below the snow line, and in the Himalaya and Tibet about the same holds good. The summer temperatures of the points where the glaciers end on the Himalaya also correspond fairly with those of the corresponding positions in European glaciers, viz., for July a little below 60° Fahr., August 58°, and September 55°.

Measurements of the movement of Himalayan glaciers have been made which also give results corresponding closely with those obtained under analogous conditions in the Alps, viz., rates from 9½ to 14½ inches in twenty-four hours. The motion of one glacier from the middle of May to the middle of October averaged 8 inches in the twenty-four hours. The average yearly motion of the glacier of the Aar is said to be 7½ inches in twenty-four hours. The dimensions of the glaciers on the outer Himalaya, where

as before remarked, the valleys descend rapidly to lower levels, are fairly comparable with those of Alpine glaciers, though frequently much exceeding them in length—8 or 10 miles not being unusual. In the elevated valleys of northern Tibet, where the destructive action of the summer heat is far less, the development of the glaciers is enormous. At one locality in north-western Ladakh there is a continuous mass of snow and ice extending across a snowy ridge, measuring no less than 64 miles between the extremities of the two glaciers at its opposite ends. Another single glacier has been surveyed 36 miles long.

In connexion with almost all the Himalayan glaciers of former times precise accounts are forthcoming are found even to-day, indicating some previous condition in which their extent was much larger than now. In the east these mountains are very remarkable, extending 8 or 10 miles. In the west they seem not to go beyond 2 or 3 miles, and they have been observed on the summit of the table-land as well as on the Himalayan slope. The explanation suggested to account for the former great extension of glaciers in Norway would seem applicable here. Any modification of the coast line which should submerge the area now occupied by the North Indian plain, or any considerable part of it, would be accompanied by a much wetter and more equable climate on the Himalayas, more snow would fall on the highest ranges, and less summer heat would be brought to bear on the destruction of the glaciers, which would receive larger supplies and descend lower. Such an explanation is not inconsistent with what is known of the geological formation of the mountains, and appears to be otherwise supported by the evidence of a greater former extension of the lakes of Tibet, and of the former existence of rivers flowing from the Himalaya between the Jumna and the Sutlej, the dry beds of which are now to be traced, in which water is never seen. Till now no geological evidence has been adduced to indicate in this region anything corresponding to the glacial epochs of northern Europe, to which these former extensions of the glaciers could be attributed.

Speaking broadly, the general types of the flora of the lower, hotter, and wetter regions, which extend along the great plain at the foot of the Himalaya, and include the valleys of the larger rivers which penetrate far into the mountains, does not differ from that of the contiguous Malayan peninsula and islands, though the tropical and insular character gradually becomes less marked as we pass from east to west, where, with a greater elevation and distance from the sea and higher latitude, the rainfall and humidity diminish and the winter cold increases. The vegetation of the western part of the plain and of the hottest zone of the western mountains thus becomes closely allied to, or almost identical with, that of the drier parts of the Indian peninsula, more especially of its hilly portions, and, while a general tropical character is preserved, forms are observed which indicate the addition of an Afghan as well as of an African element, of which last the gay lily *Gloriosa superba* is an example, pointing to some previous connexion with Africa.

The European flora, which is diffused from the Mediterranean along the high lands of Asia, extends to the Himalaya, many European species reach the central parts of the chain, though few reach its eastern end, while genera common to Europe and the Himalaya are abundant throughout and at all elevations. From the opposite quarter an influx of Japanese and Chinese forms, such as the rhododendrons, the tea plant, *Aucuba*, *Hedyscra*, *Slmima*, *Adamsia*, *Gonolium*, and others, has taken place, these being more numerous in the east and gradually disappearing in the west. On the higher and therefore cooler and less many ranges of the Himalaya the conditions of

temperatures requisite for the preservation of the various species are readily found by ascending a descending the mountain slopes, and therefore a greater uniformity of character in the vegetation is maintained along the whole chain. At the greater elevations the species which are identical with those of Europe become more frequent, and in the alpine regions many plants are found identical with species of the Arctic zone. On the Tibet plateau, with the increased dryness, a Siberian type is established, with many the Siberian species and more genera, and some of the Siberian forms are further disseminated, even to the plains of Upper India. The total absence of a few of the more common forms of northern Europe and Asia should also be noticed, among which may be named *Pinus*, *Fagus*, *Abies*, *Prunus*, *Malus*, and *Castanea*.

In the more humid regions of the east the mountains are almost everywhere covered with a dense forest which reaches up to 12,000 or 13,000 feet. Many tropical types here ascend to 7000 feet or more. To the west the upper limit of forest is somewhat lower, from 11,500 to 12,000 feet, and the tropical forms usually cease at 5000 feet.

In Sikkim the mountains are covered with dense forest of tall umbelliferous trees, commonly accompanied by a luxuriant growth of under shrubs, and adorned with climbing and epiphyt plants in wonderful profusion. In the tropical zone large figs abound, *Tournefortia*, *Shorea* (41), laurels, many *Leguminosae*, *Nandina*, *Albizia*, bamboos, and several palms, among which species of *Calamus* are remarkable, climbing over the largest trees, and this is the western limit of *Cycas* and *Melastoma* (natmeg). Plants ascend to 7000 feet. *Pandanus* and tree ferns abound. Other forms, *Santalum*, orchids, and climbing *Ardisia* are very numerous, the last named profusely adorning the forests with their splendid dark-green foliage. Various oaks descend within a few hundred feet of the sea-level, increasing in numbers at greater altitudes, and becoming very frequent at 4000 feet, at which elevation also appear *Aurinia*, *Madagala*, cherries, *Pyrus*, maple, alder, and birch, with many *Salicaceae*, *Holboellia*, *Rhus*, *Myrica*, *Synaloea*, and *Rubus*. *Rhododendrons* begin at about 6000 feet and become abundant at 8000 feet, from 10,000 to 14,000 feet forming in many places the mass of the shrubby vegetation which extends some 2000 feet above the forest. Epiphyt orchids are extremely numerous between 6000 and 8000 feet. Of the *Coniferae*, *Podocarpus* and *Pinus longifolia* alone descend to the tropical zone, *Abies* *Smithiana* and *Smithiana* and the birch (a genus not seen in the western mountains) are found at 8000, and the yew and *Pinus Walbatana* at 10,000 feet. *Pinus excelsa*, which occurs in Bhutan, is absent in the wetter climate of Sikkim.

On the drier and higher mountains of the interior of the chain, the forests become more open, and are spread less uniformly over the hill-sides, a luxuriant herbaceous vegetation appears, and the number of shrubby *Leguminosae*, such as *Desmodium* and *Indigofera* *a*, increases, as well as *Ranunculaceae*, *Rosaceae*, *Umbelliferae*, *Labiate*, *Gramineae*, *Cyperaceae*, and other European genera.

The alpine flora of Sikkim closely resembles that of the western Himalayas, and so far as generic forms are concerned, that of the alpine regions of Europe and western Asia. The vegetation of the Tibetan region appears on rising above 14,000 feet, and its last representatives reach even to 18,000 feet.

Passing to the westward, and viewing the flora of Kumaon, which province holds a central position on the chain, on the 80th meridian, we find that the gradual decrease of moisture and increase of high summer heat are accompanied by a marked change of the vegetation. The

tropical forest is characterized by the trees of the hotter and drier parts of southern India, combined with a few of European type. Among them are *Moringa*, *Bombax*, *Butea*, *Anogeissus*, *Erythraea*, *Acacia*, *Bumelia*, *Neralea*, and *Ulmus integrifolia*. *Pinus longifolia* descends almost to the level of the plains. Among the more common shrubs are *Zizyphus*, *Adiantum*, *Calotropis*, *Carissa*. Ferns are more rare, and the tree-ferns have disappeared. The species of palm are also reduced to two or three, and bamboo, though abundant, are confined to a few species.

The outer ranges of mountains are mainly covered with forests of *Pinus longifolia*, rhododendron, oak, and *Pinus* *At* *Nam-dal* *cyprus* is abundant. The shrubby vegetation comprises *Rubus*, *Indigofera*, *Desmodium*, *Berberis*, *Delonixia*, *Viburnum*, *Clematis*, with an *Arundinacea*. Of herbaceous plants species of *Ranunculus*, *Potentilla*, *Geranium*, *Thalictrum*, *Pyrola*, *Gentiana*, and many others. European forms are common. In the less exposed localities, on northern slopes and sheltered valleys, the European forms become more numerous, and we find species of alder, birch, ash, elm, maple, holly, honeysuckle, *Pyrus*, &c. At greater elevations in the interior, besides the above are met *Corylus*, the common walnut, found wild throughout the range, horse chestnut, yew, also *Pinus Walbatana*, *Pinus excelsa*, *Abies Smithiana*, *Cedrus Deodara* (which tree does not grow spontaneously east of Kumaon), and *Juniperus*. The denser forests are commonly found on the northern faces of the higher ranges, or in the deeper valleys, between 8000 and 10,500 feet. The woods on the outer ranges from 3000 up to 7000 feet are more open, and consist mainly of evergreen trees.

The herbaceous vegetation does not differ greatly, flag- genically, from that of the east, and many species of *Primulaceae*, *Ranunculaceae*, *Cruceae*, *Labiate*, and *Scrophulariaceae* occur, balsams abound, also beautiful forms of *Campulacaceae*, *Gentiana*, *Meconopsis*, *Saxifraga*, and many others.

Cultivation hardly extends above 7000 feet, except in the valleys behind the great snowy peaks, where a few fields of buckwheat and Tibetan barley are sown up to 11,000 or 12,000 feet. At the lower elevations rice, maize, and millets are common, wheat and barley at a somewhat higher level, and buckwheat and amaranth usually on the poorer lands, or those recently reclaimed from forest. Besides these, most of the ordinary vegetables of the plains are reared, and potatoes have been introduced in the neighborhood of all the English stations.

As we pass to the west the species of rhododendron, oak, *Pinus* *a* and *Magnolia* are much reduced in number as compared with the eastern region, and both the Sikhyan and Japanese forms are much less common. The herbaceous tropical and semi-tropical vegetation likewise by degrees disappears, the *Stactamineae*, epiphyt and terrestrial *Orchidaceae*, *Asceae*, *Cyrtandaceae*, and *Begonia* only occur in small numbers in Kumaon, and scarcely extend west of the Sutlej. In like manner several of the western forms suited to drier climates find their eastern limit in Kumaon. In Kashmir the plane and Lombardy poplar flourish, though hardly seen further east, the cherry is cultivated in orchards, and the vegetation presents an essentially European cast. The alpine flora is slower in changing its character as we pass from east to west, but in Kashmir the vegetation of the higher mountains hardly differs from that of the mountains of Afghanistan, Persia, and Siberia, even in species.

The flora of western Tibet is essentially European in its character. The juniper and poplar are the only trees that are seen, excepting fruit-trees, which include apricot, pear, and grape. The shrubby plants include small forms of willow, elm, *Lonicera*, rose, *Myrica*, *Sphedra*, and

Hippophae. The ordinary fuerood of the more elevated tracts is supplied by bushes of *Cotoneaster*, the furze of travellers, and dwarf *Loasea* and willow. Species of *Astragalus*, *Urtica*, *Allium*, small *Cuscuta* and saxifages, *Saxifraga*, and *Rheum* are common. *Asplenium* and many salt plants, with *Glaux maritima* and *Tylophora*, are found, especially on the borders of the salt lakes. Mosses and ferns are very rare. Many European grasses and *Carex* occur in the pastures. The herbaceous vegetation ascends freely to 10,000 feet, and isolated plants may be found as high as 19,000 feet, but excepting in the close neighborhood of small streams the growth is very scanty, and not one-twentieth of the surface is commonly clothed with vegetation. Barley is cultivated up to 15,000 feet, wheat, millet, and rape, with buckwheat, being common up to 12,000 feet. Apples and apricots grow up to 11,000 and 12,000 feet, and grapes to 9000 feet.

Number of species and characters of timber trees
The total number of flowering plants inhabiting the range amounts probably to 5000 or 6000 species, among which may be reckoned several hundred common English plants chiefly from the temperate and alpine regions, and the characteristic of the flora as a whole is that it contains a general and tolerably complete illustration of almost all the chief natural families of all parts of the world, and has comparatively few distinctive features of its own.

Timber trees
The timber trees of the Himalaya are very numerous, but few of them are known to be of much value, and the difficulties of transport are so great as to render their removal to a distance in many cases impracticable. The "Sal" is one of the most valuable of the trees, with the "Toon" and "Sissoo," it grows in the outer ranges most accessible from the plains. The "Deodai" is also much used, but the other pines produce timber that is not durable. Bamboos grow everywhere along the outer ranges, and, taken to the eastward, and are largely exported for use in the plains of India. Other vegetable products of economic value, including the ordinary cereals and esculent plants, are not numerous, and the primitive condition of the people and the difficulties and expense of carriage are so great as to render the trade in such articles very insignificant.

Tea
Though one species of coffee is indigenous in the hotter Himalayan forests, the climate does not appear suitable for the growth of the plant which supplies the coffee of commerce. The cultivation of tea, however, is now carried on successfully on a large scale, both in the east and west of the mountains, and has already become an important item of the export trade of India. In the western Himalaya the cultivated variety of the tea plant of China has been introduced, and succeeds well, on the east the indigenous tea of Assam, which is not specifically deficient, and is perhaps the original parent of the Chinese variety, is now almost everywhere professed. The produce of the Chinese variety in the hot and wet climate of the eastern Himalaya, Assam, and eastern Bengal is neither so abundant nor so highly flavoured as that of the indigenous plant, and therefore not so commercially valuable.

Opium
The cultivation of the cinchona, several species of which have been introduced from South America and naturalized in the Sikh Himalaya, is still in its infancy, but promises to yield at a comparatively small cost an ample supply of the precious febrifuge that is extracted from its bark. At present the manufacture is almost wholly in the hands of the Government, and the drug prepared is all disposed of in India. The progress of cinchona cultivation on the Nilgeries is not less promising than on the Himalaya.

Zoology
General characteristics
The general distribution of animal life on these mountains is manifestly determined by much the same conditions that have controlled the vegetation. The connection with Europe on the north-west, with China on the north-east, with Africa on the south-west, and with the Malayan region on the

south-east, is manifest, and the greater or less prevalence of the European and Eastern forms varies according to more western or eastern position on the chain. So far as is known these remarks will apply to the extinct as well as to the existing fauna. The Palaeozoic forms found in the Himalaya are very close to those of Europe, and in some cases identical. The Tertiary fossils are still more closely allied, more than a third of the species being identical. Among the Jurassic Mollusca, also, so many species that are common in Europe. The Siwalik fossils contain 84 species of mammals of 45 genera, the whole bearing a marked resemblance to the Miocene fauna of Europe, but containing a large number of genera still existing, especially of ungulates, and as before stated now held to be of Pliocene age.

The fauna of the Tibetan Himalaya is essentially European, rather than of the northern half of the old continent, which region has by zoologists been termed Palearctic. Among the characteristic animals may be named the yak, from which is reared a cross breed with the ordinary horned cattle of India locally called "zebu," many wild sheep, and two antelopes, as well as the muskdeer, several hares and some burrowing animals, including pikas (*Lepus*) and two or three species of mountain cats. Among the carnivores—dog, wolf, hyena, ounce, marten, and ermine, also wild ass. Among birds are found bustard and species of sand-grouse and partridge, water-fowl in great variety, which breed on the lakes in summer and migrate to the plains of India in winter, the raven, hawk, eagle and owl, a magpie, and two kinds of chough, and many smaller birds of the passerine order, amongst which are several finches. Reptiles, as might be anticipated, are far from numerous, but a few lizards are found, belonging for the most part to types, such as *Phrynosoma*, characteristic of the Central Asiatic area. The fishes from the head waters of the Indus also belong, for the most part, to Central-Asiatic types, with a small admixture of purely Himalayan forms. Amongst the former are several peculiar small-scaled carps, belonging to the genus *Schizothorax* and its allies.

The ranges of the Himalaya, from the border of Tibet or Hindustan to the plains, form a zoological region which is one of the richest of the world, particularly in respect to birds, to which the forest-clad mountains offer almost every range of temperature.

Only two or three forms of monkey enter the mountain ranges, the langur, a species of *Simulapithecus*, ranging up to 8000 or 9000 feet. No lemur occurs, although a species is found in Assam, and another in southern India. Bats are numerous, but the species are for the most part not peculiar to the area, several European forms are found at the higher elevations. Moles, which are unknown in the Indian peninsula, abound in the forest regions of the eastern Himalaya at a moderate altitude, and shrews of several species are found almost everywhere, amongst them are two very remarkable forms of water-shrew, one of which, however, *Neotoma*, recently discovered, is probably Tibetan rather than Himalayan. Bears are common, and so are martens, several weasels and otters, and cats of various kinds and sizes, from the little spotted *Felis bengalensis*, smaller than a domestic cat, to animals like the clouded leopard rivaling a leopard in size. Leopards are common, and the tiger wanders to a considerable elevation, but can hardly be considered a permanent inhabitant, except in the lower valleys. Civets, the mungoose (*Ichneumon*), and fox-cats (*Felis adamsi*) are only found at the smaller elevations. Wild dogs (*Cynus*) are common, but neither foxes nor wolves occur in the forest area. Besides these carnivores some very peculiar forms are found, the most remarkable of which is *Skunks*, sometimes called the cat bear, a type

peculiar to the Himalaya. Two other genera, *Melotis*, an aboriginal bullock, and *Protonotus*, an aboriginal civet, are representative of Malaya in type. Amongst the rodents squirrel, abundant, and the so-called flying squirrel with a remarkable organ sent on parachute between their fore and hind legs, are represented by several species. Rats and mice, various, both kinds and individuals being numerous, but few present much peculiarity, a bamboo rat (*Rhizomys*) from the base of the eastern Himalaya being perhaps most worthy of notice. Two of these species of vole (*A. nicola*) have been detected, and porcupines are common. The elephant is found in the outer forests as far as the Jumna, and the rhinoceros as far as the Sarda, the spread of both of these animals as far as the Indus and into the plains of India, far beyond their present limits, is substantiated by historical records, they have probably retreated before the advance of cultivation and fire arms. Wild pigs are common in the lower ranges, and one peculiar genus of pigmy hog (*Porcula*) of very small size inhabits the forest at the base of the mountains in Nepal and Sikkim. Deer of several kinds are met with, but do not ascend very high on the hill sides, and belong exclusively to Indian forms. The musk deer keeps to the greater elevations. The chevrotains of India and the Malay countries are unrepresented. The goat or wild ox is found at the base of the hills. Three very characteristic mammals, having some affinities with goats, inhabit the Himalaya, these are the "snow" goat, and "ibex," the first being ranged to rather high elevations. Lastly, the penguin or manis is represented by two species in the eastern Himalaya. A dolphin living on the Ganges ascends that river and its affluents to their issue from the mountains.

Birds.—Almost all the orders of birds are well represented, and the marvellous variety of forms found in the eastern Himalaya is only rivalled in Central and South America. Eagles, vultures, and other birds of prey are seen soaring high over the highest of the forest clad ranges. Owls are numerous, and a small species, *Glaucidium*, is conspicuous, breaking the stillness of the night by its monotonous though musical cry of two notes. Several kinds of swifts and nightjars are found, and gorgeously-coloured trogons, bee eaters, rollers, and beautiful kingfishers and barbets are common. Several large hornbills inhabit the highest trees in the forest. The parrots are restricted to parakeets, of which there are several species, and a single small lory. The number of woodpeckers is very great, and the variety of plumage remarkable, and the voice of the cuckoo, of which there are numerous species, resounds in the spring as in Europe. It is impossible to do more than indicate some of the chief passerine birds, their number is immense. Amongst them the snipe-bird resembles in appearance and almost rival in beauty the humming-bird of the New Continent. Chacquets, nuthatches, shrikes, and then allied forms, flycatchers and swallows, thrushes, dippers and babblers (about fifty species), bulbuls and oilouls, peculiar types of redstarts, various sylviads, wrens, tits, crows, jays, and magpies, weaver-birds, avadavats, sparrows, cisticolids, and many finches, including the exquisitely coloured rose finches, may also be mentioned. The pigeons are represented by several wood-pigeons, doves, and green pigeons. The gallinaceous birds include the peacock, which everywhere adorns the forest bordering on the plains, jungle fowl, and several pheasants, partridges, of which the chukra may be named as most abundant, and snow pheasants and partridges, found only at the greatest elevations. Waders and waterfowl are far less abundant, and those occurring are nearly all migratory forms which visit the peninsula of India,—the only important exception being two kinds of solitary snipe, and the red billed curlew.

Of the reptiles found in these mountains many are Reptiles peculiar. Some of the snakes of India are to be seen in the hotter regions, including the python and some of the venomous species, the cobra being found as high up as 8000 or 9000 feet, though not common. Lizards are numerous, and as well as frogs are found at all elevations from the plains to the upper Himalayan valleys, and even extend to Tibet.

The fishes found in the rivers of the Himalaya show the same general connexion with the three neighbouring regions, the Palaearctic, the African, and the Malayan. Of the principal families, the *Acanthopterygii*, which are abundant in the hotter parts of India, hardly enter the mountains, two genera only being found, of which one is the peculiar amphibious genus *Ophiocephalus*. None of these fishes are found in Tibet. The *Siluridae* or scaleless fishes, and the *Cyprinidae*, or carp and loach, form the bulk of the mountain fish, and the genera and species appear to be organized for a mountain torrent life, being almost all furnished with suckers to enable them to maintain their positions in the rapid streams which they inhabit. A few *Siluridae* have been found in Tibet, but the carps constitute the larger part of the species. Many of the Himalayan forms are Indian fish which appear to go up to the higher streams to deposit their ova, and the Tibetan species as a rule are confined to the rivers on the border of the mountains at the greatest elevations. The characteristics of the fishes are Tibetan rather than Himalayan. The *Salmonidae* are entirely absent from the waters of the Himalaya proper, of Tibet, and of Turkestan east of the Terekist. On crossing the watershed that leads from the streams flowing into the Indus to those falling into the Oxus, a trout is reported to have been found, though it is said not to live in the Jaxartes or its affluents.

No such general or connected account of the Mollusca, Other insects, or other lower forms of life, of these mountains exists as will admit of anything but very vague statements regarding them. It is, however, indicated that the same relations with the neighbouring European, Asiatic, and African regions are found to exist as have been noticed as characterizing the other forms of life.

Of the land Mollusca, one half appear to belong to the genera *Helix* and *Bulimus*, and about one-third to the family of *Cyclostomidae*, the species appear to be for the most part very local, and of about 120 species in all, only about one-tenth are recorded as being found in Tibet or the highest Himalayan valleys.

The Himalayan butterflies are very numerous and brilliant, for the most part belonging to groups that extend both into the Malayan and European regions, while African forms also appear. There are large and gorgeous species of *Papilio*, *Argynnis*, *Morpho*, and *Danaides*, and the more favoured localities are described as being only second to South America in the display of this form of beauty and variety in insect life. Moths, also, of strange forms and of great size are common. The cicada's song resounds among the woods in the autumn, flights of locusts frequently appear after the summer, and they are met far within the mountains, carried by the prevailing winds even among the glaciers and eternal snows. Ants, bees, and wasps of many species, and flies and gnats in great variety of form, and possessed of equal variety of powers of annoyance, abound, particularly during the summer rainy season, and at all elevations.

Apart from the connexion which subsists between the Himalaya and the earliest developments of the Hindu religion, there is little in these mountains that is of interest as throwing light on the earlier history of our race. The mythical geography of the Hindus represents the peak of Kailas, the snowy mountain north of the Tibetan lake

Belation of Manasarovari, as the centre of the world, around which its visionary kingdoms are spread out. The sanctity of the Himalaya, in Hindu mythology, is known to all, and thousands of pilgrims from all parts of India still continue to seek salvation in the holy waters of the Ganges, and at its sacred sources in the snowy Himalaya. "He who thinks on Himachal," says the M'tas khand, one of the Puranas or holy books of the Hindus, "though he should not behold him, is greater than he who performs all worship at Kashi (Benares)." In a hundred ages of the gods I could not tell of the glories of Himachal. As the dew is dried up by the morning sun, so is the soul of mankind by the sight of Himachal!" And to those who have performed such a pilgrimage the wondrous snow-clad peaks of the Himalaya, though seen through the atmosphere of the 19th century, seem still to be surrounded with the same halo of glory as of old.

The Ganges, which issues from the mountains at Haridwar, is fed by two principal tributaries which unite about 40 miles higher up, the Alaknanda, far the larger, and the Bhagirathi, the more sacred. The source of the last-named river is in the glacier above the temple at Gangotri, which lies to the north of a great cluster of snowy peaks, on the south of which is found the temple of Kedarnath, and on the east that of Badrinath. Large glaciers exist near both of these temples, that near Kedarnath feeding the Mandakini, and that near Badrinath feeding the Vishnuganga, which river gives the main supply of water to the Alaknanda. Both the valley above Gangotri and that above Badrinath lead to Tibet, passing through a region of snowy peaks of first-class magnitude. To the west of Gangotri and the Bhagirathi lies the hardly less sacred source of the Jumna and the temples of Jammot.

The temple at Badrinath, on the Vishnuganga, as the latter name suggests, is dedicated to Vishnu, and is served by priests of the Vishnuv sect, presided over by a "Rajwal" or abbot, who is invariably a Brahman from South India. The temple at Kedarnath is dedicated to Shiva, symbolised by the Lingam, and is most especially venerated by the Shiva sect, and the chief priest here, too, is a Brahman from Malabar in the same part of India. The origin of this connexion of the holy places in the Himalaya with southern India is very obscure, possibly, however, it dates back to the 8th or 9th century, to the time of Sankara Acharya, a native of Malabar, the chief expositor of the Shiva doctrine, who is said to have died at Kedarnath. That the Himalaya and the sources of the Ganges, however, were regarded as holy, and had become places of pilgrimage for Hindus long before this event, or before the development of the two sects that have been here specially named, there can be no reasonable doubt, but how or when the Aryan races of India first developed for themselves a system of mythology so intimately bound up with these mountains must ever remain a subject of mere speculation.

Remains of Buddhist monasteries and temples on a great scale, the majority of which are believed from inscriptions found on them to date back to about the commencement of the Christian era, are met with along the foot of the western end of the Himalaya, in the Yusufzai country bordering on the Indus, and similar ruins are seen as far west as Jellalabad in Afghanistan. Some of the buildings are the doubtless days of Buddhism, about six centuries before our era, and the discovery in this locality of what is probably a contemporaneous copy of Asoka's well known inscription, cut into the face of a great rock, testifies to the development of a great centre of Buddhism in his days, that is, about 250 B.C. Among these ruins are found fragments

of sculpture bearing the impress of the Greek art introduced by the successors of Alexander, and other ideas of the Greek sculptor, in the form of numerous coins, have been obtained from the same quarter. The exact point at which Alexander entered India is still a subject of discussion among antiquaries, but it probably was on the line following the skirt of the north-west Himalaya along which the road now runs, and which is known to have been the chief line of traffic for centuries. How the influence of Greek architecture was carried forward both in time and place is illustrated by the enormous temple of the sun, or "Maitland," in the valley of Kashmir, the date of which is about 400 A.D.

It would be a task, certainly fruitless, and probably impossible, to endeavour to estimate aright the comparison of the fictitious claims to admiration of the scenery of the Himalaya and other great mountain ranges. If some elements of the picturesque be better found elsewhere, and if the softer features of hill, valley, and lake be absent, yet nowhere can the Himalaya be surpassed in the magnificence and variety of its forests, or in the wealth and beauty of its alpine flora, which offer to the traveller ever changing and ever-renewed pictures, combining the charm of former memories with fresh conceptions of the wonderful never failing profusion of nature, and to the student of natural phenomena of every description surely no grander field will ever be open than that presented by these mountains.

In many circumstances mere magnitude may not be so effectual in adding to the apparent grandeur or sublimity of the mountain scenery, for everywhere the features nearest to the eye, though absolutely smaller, may cut off from view those of far greater importance which are further removed. And this is often conspicuously true in the valleys of the Himalaya. But the extraordinary scale on which every part of the mountains is developed, the actual vast dimensions of the main features, the apparently endless succession of ranges after range, of ascent and descent, of valley and mountain top, of river, torrent, and brook, of precipitous rock and grassy slope, of forest and cultivated land, cannot fail to produce impressions of wonder, which are not likely to be equalled and certainly will not be exceeded on any other chain. Upon these mountains alone, of all on the earth, can the traveller, as he climbs their slopes, obtain at a glance a range of vision extending 5 miles in vertical height, from 2000 or 3000 feet to 29,000 feet above the sea, and see spread out before him a compendium of the entire vegetation of the globe from the tropics to the poles. Here may the eye as it sweeps along the horizon embrace a line of snow-clad mountains, such as exist in no other part of the world, stretching over one-third of the entire circle, at a distance of 40 or 50 miles, their peaks towering over a sea of intervening ranges piled one behind another, whose extent on either hand is lost in the remote distance, and of which the nearest rises from a gulf far down beneath the spectator's feet, where may be seen the silver line that marks a river's course, or crimson fields of amaranth and the dwellings of man. Sole representative of animal life, some great eagle floats high overhead in the pure dark-blue sky, or, unused to man, fearlessly sweeps down within a few yards to gaze at the stranger who intrudes among these solitudes of nature. As the sun sinks the cold grey shadow of the summit where we stand is thrown forward, slowly stealing over the distant hills, and, veiling their glowing purples as it goes, carries the night up to the feet of the great snowy peaks, which still rise radiant in rosy light above the now darkening world. From east to west in succession the splendour fades away from one point after another, and the vast shadow of the

oath is rapidly drawn across the whole vault of heaven. One more departing day is added to the countless years which have silently witnessed the death-like change that passes over the eternal mow as they are left lying their cold pale fronts against the now leaden sky, till slowly

with the deepening night the world of mountains rises again, as it were to a new life, under the changed light of the thousand stars which stud the firmament and shine with a brilliancy unknown except in the clear starless air of these sublime heights (s. s.)

HIIMERA, a city on the north coast of Sicily. It was founded in 648 B.C. by the Chalcidian inhabitants of Zancle, but with them were many Syracusan exiles who gave to the language of the city a Doric character. Early in the 5th century the tyrant Telesias, being expelled by Theron of Agrigento, invoked the aid of the Carthaginians. They gladly availed themselves of the pretext, but their general Hamilcar was defeated at Himera by the Greeks under Gelon of Syracuse (480 B.C.). Thrasydæus, son of Theron, brought a large body of Doric immigrants to the city in 476, but was not long after expelled by Hiero. It seems to have enjoyed great prosperity during the rest of the 5th century. In 415 it refused to admit the Athenian fleet, and was a zealous ally of Syracuse. In 408 the Carthaginians sent another great army under Hannibal, grandson of Hamilcar, who razed the city to the ground. A new city called Thermae Himenses was founded in 407 a few miles to the former site. This name was derived from the famous hot springs, in which Hieron was said to have bathed. The new city was in Carthaginian hands till it was annexed by the Romans in the Second Punic War. It was treated with peculiar favour by them, and was left a free city under its own laws. In the time of Cicero it was a flourishing town, though not very large. Under Augustus it became a "colonia." We hear little of it from that time, though the site was never deserted, and the town still exists under the name of Termini. Ergoteles, an Olympian victor, celebrated by Pindar (*El. vi*), was a citizen of Himera. Stenichon, the poet, was a native of the city, and his statue was preserved at Thermae in the time of Cicero. Agrigento also was a native of Thermae.

HIMMEL, FRIDRICH HENRY (1765-1814), a German composer of male, was born November 20, 1765, at Truenhützen in Brandenburg, Prussia, and originally studied theology at Halle. During a temporary stay at Potsdam he had an opportunity of showing his self-acquired skill as a pianist before King Frederick William II., who thereupon made him a yearly allowance in order to enable him to complete his literary studies. This he did under Naumann, a German composer of the Italian school, and the style of that school Himmel himself adopted in his serious operas. The first of these, a pastoral opera *Il Primo Navigatore*, was produced at Venice in 1794 with great success. After his return to Berlin in 1795 Himmel became court chapel master to the king of Prussia, and in that capacity wrote a great deal of official music, such as cantatas, a coronation to Dorn, and the like, now justly forgotten. The same fate is shared by his Italian operas, successively composed for Stockholm, St. Petersburg, and Berlin, and all received with great applause in their day. Infinitely more important than these is an opéra-comique to German words called *Funken*, the popularity of which has seldom been surpassed. Although antiquated it still remains an admirable specimen of the primitive form of the musical drama known in Germany as the "Singspiel." Himmel's gift of writing genuine simple melody, to which the opéra-comique owes its success, is also observable in his songs, amongst which one called "To Alexia" is the best. It may be found in the first volume of the *Musical Library*. Himmel died at Berlin, June 8, 1814.

HINCKLEY, a market town of England, county of Leicester, is situated 13 miles S.W. of Leicester, on a branch

line between that town and Nuneaton, which connects the London and North Western and the Midland railways. The principal buildings are the church of St. Mary, a Gothic structure lately restored, with tower and spire 120 feet high, the town-hall, the parsonage and Roman Catholic academy named St. Peter's Priory, and the union workhouse, erected in 1838, with accommodation for 400 inmates. There are a grammar school, a national school, and board schools. Hinckley is the centre of the stocking-weaving district, and its speciality is circular hose. It also possesses breweries, brick and tile works, and lime works. There are several mineral springs in the neighbourhood, and at one of these baths have been erected. The population in 1871 was 6902.

Hinckley was created a Baroncy soon after the Conquest, when it was held by Hugh de Grentemont, who created a castle, the ditch of which is still traceable, and also founded a priory of Benedictine monks. Originally the town had the privileges of a borough, but these were annulled by Edward IV. Attention is made of "Hinckley Run" in the second part of *Henry IV.*, act v. sc. 1.

HINCMAR (c. 806-882), archbishop of Rheims from 845 to 882, a prominent figure in most of the theological and ecclesiastical struggles of his day, and perhaps the most vigorous and influential prelate France has ever produced, belonged to a noble West-Frisian family, and was born about the year 806. Other forms of the name are Ingumar, Ingmar, and Igmur. His early education was received at the abbey of St. Denis under Hilduin (the author of *Arceopagica*), whom he followed to Corvey, Westphalia, where banished by Louis the Pious in 830 for having joined the party of Lothar. Returning about two years afterwards along with his superior to St. Denis, of which he had become a canon, he resided partly there and partly at court, where he rapidly rose high in the royal favour. He was with Louis at the "Field of Frischhof" (Campus mendacium) in Aachen, and was one of the few who remained faithful when the majority of the prelates and nobles went over to the other side. After the death of Louis (840), he equally gained the confidence of Charles the Bald, though through his influence, after he had successively held the abbacy of St. Mary's, of Compiègne, and of St. Genois, he was in 845 elected to succeed the deposed Ebo or Elbo in the archiepiscopal see of Rheims. Having exacted from Charles a full restitution of all the church property which had belonged to the diocese, and a further promise that it should never again be alienated, he at once entered on the duties of his office, and took a leading part in the council of Meaux (O. Meldeuse), the reforming decrees of which so strongly roused the opposition of the king. Some attempt having been made to revive the claims of Ebo, Hincmar's title to the archbishopric was confirmed by a synod of French bishops at Paris, and ultimately settled by Leo IV.'s transmission of the pallium in 847. Apart from the ordinary affairs of his diocese, which included the completion and adornment of the cathedral begun by his predecessor, he now became deeply involved in the discussions which arose out of the predestinarian views of Gottschalk (see GOTTSCHALK), whom Hincmarus Manius, at the synod of Mainz (848) had caused to be relegated to Hincmar as his metropolitan. At a synod held at Quierzy on the Ouse (Carisacum), in the diocese of Soissons, in 849, Hincmar had united with Wemlo of Sens and other prelates in condemning the refractory monk to degradation, scourging,

and imprisonment, but in a short refutation of the "predestination heresy," which he himself shortly afterwards wrote and circulated, he so failed to do justice to the orthodox faith as to elicit the censure of Ratamnus of Corvey, who was afterwards supported by Prudentius of Troyes, Lupus of Ferrières, and a large Augustinian party (850). Hincmar now summoned the dialectic skill of John Scotus Erigena to his aid, and the controversy became general. Another synod held at Querry in 855 passed the four "Capitula Carissaca," which in substance taught that there is but one divine predestination, that free will, lost by the fall, is restored by the preventing and assisting grace of Christ, that God wills generally that all men should be saved, and that the blood of Christ was shed for all. These were answered by the six canons of the (Lotharingian) synod of Valence, which elected from Hincmar, two years afterwards, the *De Predestinatione Dei et Libero Arbitrio Libertatis*, of which all that is now extant is the prefatory letter to the king. By the synod of Langres (S. Longonensis, 859), however, the articles of Valence were confirmed,—a decision which was afterwards supported by the general synod held at Savona or Savonnes, otherwise known as the Concilium Tullense (859). Hincmar now published the *Posterior de Predestinatione Dei et Libero Arbitrio Dissertatio*, but without influencing the voice of the church, and he was more successful in his controversy with Gottschalk on the Trinity, his *Collectio ex Sanctis Scripturis et Orthodoxorum Doctorum* against the phrase "Trina Deitas" having been totally disregarded, he had, however, the satisfaction of preventing the release of Gottschalk, who died in prison in 868. While these speculative controversies were doubtfully raging, Hincmar found scope for his greater practical talent in the events which followed the death of the emperor Lothar in 855, and which chiefly resulted in the strengthening of clerical ascendancy. Having saved Charles from the hands of his own nobles and of the Comman, the great metropolis was in a position at last to say, "If kings rule after God's will, they are subject to none, if they be great sinners then is their judgment in the hands of the bishops." In 860 began the divorce suit in which the interests of Thietberga, the oppressed queen of Lothar II, were involved, and here, undoubtedly, the whole weight of Hincmar's influence was thrown into the scale of morality and right. His contribution to the discussion is still extant in the treatise *De Divortio Lotharii et Thietbergæ Reginæ* (860). While this controversy still remained unsettled, Hincmar became involved in a struggle with the pope (Nicholas I.), which is of very considerable historical importance from the part which was played in it by the newly introduced "Indormen" decretals, and from the effect which it had in limiting the rights of metropolitans. Rothad, bishop of Soissons, having been deposed for acts of insubordination and violations of duty as a synod of Soissons presided over by Hincmar in 863, had appealed to Rome, the appeal had been sustained, and ultimately in 865 orders were given that the judgment of Hincmar should be reversed, and that his suffragan should be restored to his office. The decision, which, though not without murmuring and contentions, was acquiesced in by Hincmar, was an important step in the development of the hierarchical monarchy of Rome. Hincmar was somewhat more successful when he found himself in opposition to the successor of Nicholas, Adrian II. This pope, who highly disapproved of the action of the archbishop in crowning Charles as the successor of King Lothar of Lorraine in 869, had fulminated threats of excommunication against all who had been concerned in that action, Hincmar replied that the Roman see had no right to interfere in such a matter, and that the impending ban would have no validity, and the actual result was that, notwithstanding

also the protest of the emperor and the prohibition of the pope, Charles the Bald and Louis the German quietly divided the dominions of their nephew Agau, when Hincmar of Laon, his nephew and suffragan, had died his authority and appealed to the pope, a long controversy resulted in the appellant's being imprisoned, degraded, and sentenced to the loss of his eyes (871). Of the remaining years of Hincmar's life few incidents are recorded, in 882 he was compelled by Norman invasion to transfer his see to Eprenay, where in the same year he died.

The works of Hincmar, which include, besides the already mentioned, a variety of epistols and other occasional pieces, were first edited by Simund in 2 vols. fol. (1645). They are reprinted in *Migne's Cursus Pat. Comp. The Annals Breviarum* from 861 to 882 are also by Hincmar. See Goss, *Mittelhochdeutsche Literatur und Leben* and *Skizzen Hincmars* (1896), Friedl., *The Life and Times of Hincmar* (1849), and Noorden, *Hincmar, Bisthof von Rheims* (1863).

HINDLEY, a manufacturing town of Lancashire, is situated on the Lancashire and Yorkshire railway, 3 miles south-east of Wigan. Cotton spinning and the manufacture of cotton goods are the principal industries, and there are extensive coal mines in the neighbourhood. Hindley possesses a grammar school, and among its places of worship may be mentioned the old parish church, and St Peter's church, erected in 1854 in the First Pointed style. In the time of the Puritan revolution Hindley church was pulled down by the Cavaliers, who played at cards in the pews, emptied the pulpit, and tore the bible in pieces. The population in 1871 was 10,627.

HINDOL, one of the tributary states of Orissa, India, situated between 20° 29' 30" and 20° 49' 30" N lat, and between 85° 8' 35" and 85° 31' 15" E long. It is surrounded on all sides by native states, being bounded on the N and E by Dhankhal, on the S by Baramba and Narmapur, and on the W by Angul. Area, 312 square miles, population (1872), 28,025 (Hindus, 23,346, Mahometans, 142, and "others," 4568). The Cuttack and Sambalpur highroads run through the state. Only five villages contain upwards of 100 houses. Hindol consisted originally of three or four petty states, completely buried in jungle, and ruled by separate chiefs, till two Marhatta brothers, belonging to the family of the Kimidi Râjâ in Madras, drove them out, and formed their territories into one principality. The present chief maintains a military force of 83 men, and a police force 133 strong. His estimated annual revenue is returned at £2082, tribute, £55.

HINDÚ KŪSH is a title applied to the line of alpine watershed stretching W S W from the southern margin of Pamir, the Caucasus of Alexander's historians, which divides Afghanistan in a general sense from Afghan Turkestan, and the basin of the Cabul river from the basin of the Oxus. Looking towards the heart of a map of Asia, the eye is caught by that remarkable point where the great highland seems clenched as it were to a knot, whence expand in different directions (1) to east and south-east the great Tibetan plateau, (2) to north that of Pamir, and (3) to west that of Khorasan and Persia. Between the diverging masses run up the great basins of the Indus, the Yarkand river, and the Oxus. Some dim memory of these great features perhaps, transformed and transplanted further east, appears in the cosmography of the Puranas, in which the mythical Ganges falling on Mount Manu divides into four great rivers flowing to the cardinal points.

This is the first impression. But, imperfectly as we yet know the mountain structure, the more we learn the more evanescent becomes this idea of triplicity as typifying the true skeleton. This node is in fact the place of contact or intersection of two great elevations,—(1) of the Himalaya,

of which the axial lines approach in a direction from S E to N W, and (2) of the Than Shih and allied ranges, of which the axial lines run from E N E to W S W. The parallelism of Hindu Kush seems to attach it to the latter system.

The definition of geographical features must often be in part arbitrary, but that of Hindu Kush fairly comports with natural limits. On the east we take it as commencing at the Daroghl Pass, leading from the high valley of Little Pamir south into the valley of Kāshghar or Chitral. Just east of this is a cluster of peaks of great altitude, but their alignment attaches them to the great Gilgit range of the Himalaya (Mörtagh of some maps, *Droptung* of Richtofen). On the west we regard Hindu Kush as including and terminating at the Illyguk Pass, those most commonly used between Cabul and Turkestan. West of this the range continues as a watershed of considerable altitude, but with a partial change of direction and loss of true alpine character. In maps this prolongation is styled Koh-i-Baba. Properly Koh-i-Baba is the name of a conspicuous three peaked mountain rising over the Illyguk Pass, to a height of at least 10,500 feet, which we regard as the terminal prominence of Hindu Kush, though it is in truth also isolated from the higher summits to the eastward, which especially claim that name, by a considerable interval of lower mountain, rounded and naked.

The total length of Hindu Kush as thus defined is 365 miles. Towards the eastern extremity the watershed perhaps emerges little from the table-land, for the Baroghl Pass is of singularly even acclivity on both sides, and no prominent summits adjoin it on the west. But for the rest of its extent the mountain tract of Hindu Kush realizes the popular idea of an alpine chain, *sc.*, of an unpeered mountain barrier whose passes are never far below the line of perpetual snow, and whose highest peaks are never very far from the watershed.

The general altitude of the "cols" or passes runs from 12,000 to 13,000 feet. We give those that have been calculated (besides which some 20 or 22 are known more vaguely), beginning from the east —

	Eng	Feet
1 Baroghl Pass	78°28'	12,000
2 Nākin "	71°37'	17,000
3 Pan "	71°24'	18,000-16,600
4 Kilmak "	69°39'	12,300
5 Shalung "	68°17'	12,000
6 Kushan "	68°17'	12,000
7 Lak "	67°52'	12,900
8 Kūi "	67°45'	12,480

The three highest (2, 3, 6) do not rest upon any observations of barometrical or boiling point, but on other and looser data. Of the height of the peaks we have nothing definite. Captain Burnes, who ascended Koh-i-Baba with Lieutenant Smith in 1840, speaks of seeing the lofty peaks to the eastward "many thousand feet" above, and Burnes uses similar language. The great peak near the Kushan Pass, sometimes especially called Hindu Kush, which is seen at once from Cabul on the south and from Kunduz on the north, is probably not less than 20,000 feet high. Much farther east the estimated heights of passes 2 and 3 indicate probable summits of as great altitude. A great mountain due north of Chitral, called Tūch Mū, and said to be visible from a great part of Kāfiristan and from Zebik in Badakhshan, is estimated by Major Biddulph, who also has seen it, at the enormous height of 37,000 feet, but General Walker reduces this to 23,000 with a (?).

Apart from this exceptional peak we shall form a just conception of the calibre of Hindu Kush among the ranges of the world if we class it with the French and Swiss Alps in extent and mass, but with greater average altitude. We have only one report of a glacier, *viz.*, on the Nūksān Pass, No. 2 in the list of heights above.

The idea of a distinct southern range running parallel to Hindu Kush, north of the Cabul river, which Wood calls, "the Himalaya," is founded on misconception. But peaks have been measured on the spurs which run south on both sides of the Kunur river. They rise to near 10,000 feet on the left bank, east of Chitral, descending to 11,800 near the Afghan boundary. In Kāfiristan there are peaks on these spurs of 16,600 and 16,800 feet, and even within 25 miles of the Cabul river are some as high as 14,000 feet.

On the south side of Hindu Kush the earliest sources of the Helmand are in the gorges up which the Koh-i-Baba passes mount. All the rest of the range drains on that side to the Cabul river, and so to the Indus. On the north all the drainage reaches the Oxus.

Both hydrographic features and the limits of our knowledge conveniently divide the Hindu Kush into three sections.

(1) Beginning from the east, in the first section, drainage southward is into the Chitral valley, and thence the great, perhaps greatest, contributory to the Cabul river, known as the Kunur or Balam (probably *Changpas* and *Adamantash* of the ancients). The highest part of this basin is known as Chitral, *Chitral* (proper), and is politically united to Yaman in the Gilgit basin (see Gilgit). It consists of two or three confluent valleys, some of them thick with villages, whose continuous cultivation, supported by copious springs, extends far up the hill side. At Chitral, the chief place, stands 7600 feet high, in 86° 10' N lat. Twenty miles farther down is the boundary of Lower Chitral or Keshgar. This forms a sort of which the chief or Kong (so is styled "Bashk"?) is at Chitral town (height 9200 feet, 87° 59' N lat.). The people at Moleim, apparently a converted section of the neighbouring Kāshis, and speaking a kindred dialect of Sankata, claim that it is good, including fine grapes, and the wine is more famous. Chitral is the focus of Chinese geography, the impunctum at which so long perplexed and vitiated the geography of the Panu highlands. The name *Balash* more overtly conveys a larger tract, probably the whole of the then present Kāshghar, and is due to the Indians. Below Chitral the valley narrows, and is shut in by Kāsh villages in nominal subjection to the small state of Asma (25° 4' N lat). Afghan territory begins at Maseon, 20 miles farther down. On the north of this, which marks most part of the drainage flows directly into the Little Pamir stream of the Oxus, or into the Pamir, the union of the streams from Tajik and Great Pamir. We have accounts of the passes immediately west of Baroghl, though certainly they exist. From Asma, and the boundary of Upper and Lower Kāshghar, a pass crosses (about 72° E long) to Ishirgah on the Pamir. At the western limit of the section are the lofty peaks of Nūksān, Kūtesh, Agam, and Dor, which lead through the Badakhshan mountains to the Yagdo branch of the Kokcha or river of Badakhshan. On the "Nūksān" (quasi *Pas Mada*) in descending towards Chitral the traveller is girt with a leather girth, and slides down the snow. Passes, with fast food, are rolled off by the Chinese, says the native authority, "both men and beasts generally reach the bottom in safety."

(2) The next section is that of which we know least. It embraces on the south Kāfiristan, never yet penetrated by European travellers. There is a pass south to Kāfiristan from Zebik and Sanglich, and one from Kuram, probably several more. The chief streams southward are that of Pech, joining the Kunur river at Chigaz Sans (*Changpas* as of Salt in 1840), and the Abang and Alishang, which unite in Laghman, formerly Lūmghā (*Lamghā* of Ptolemy), and join the Cabul river at Chabab about 30° 15' lat. West of Kāfiristan are the Afghan valleys of Tāgo and Nūgan, hardly better known, and occupied largely by Pasdaran, and seemingly akin to the Kāshis. On the north side the valleys form main ships or cantons among the complices of small states, issuing along one to Badakhshan, and several of them having their peculiar district of old Persian affinity. One of these is Kāshghar, down which flows the Jam branch of the Kokcha. It is a wild glen near the border of Kāfiristan, occupied in a local rhyme with the eyes of hell, but which in the 8th century was of sufficient salubrity as a state to send a mission of homage to the Chinese court — such disproportionate pretensions being probably due to its containing the mines of Israh, famous for ages, commemorated by Marco Polo, and mined by Lieutenant Wood in 1838. Adjoining this are the valleys of Mangan and Arunghān, high valleys of the Chinese court, which knew the names. Their streams chiefly bear north west, and join the river of Tāghan, which carries them to the river of Kunduz, and so into the Oxus about 68° 18' E long.

(3) The last section extends from the borders of Kāfiristan to the

Koh-i-Baba. On the south the drainage is received by two distinct channels flowing parallel to the watershed in opposite directions,—the Panjshir (or Panjshir) from the east, and the Ghorband river from the west, meeting near Chitral and flowing S E to meet the river from Chitral in the Panjshir valley. The Panjshir is fruitful, with irrigated orchards and mulberry gardens, the chief support of the people, though these, of Pashai kindred, have for ages borne a reputation for ruthless turbulence. It contains silver mines, worked at an early date, and early Mahometan coins have been found in the mint in the vicinity of the Panjshir and Andakab,—the latter place north of the mountains, head of a canon subject of Kunder. From the Panjshir to the Andakab valley lead at least seven passes, the chief of these is Khawak, crossed by Wood from the north in 1838, and nearly 1200 years ago before (841) by Hsien Tsang from the south. The Tuli Pass, a loop to this, was crossed by the pit of Timur on his march to India (1398). From the Ghorband valley there are also seven or more passes, two from Paurin, one of which, Sar ulung, was attempted unsuccessfully by Wood and Lord in November 1847,—since crossed and surveyed by Herivel. Hyder Shah (1870) South in Pass, under the good peak, was succeeded by Leach and Lord in October 1877. Four of the Ghorband passes descend on the lower Andakab valley, two into the Sulikab river, coming from the valleys about Baman. The last, the pit of Shah, ascends from the top of Ghorband valley, and descends on that of Baman near the castle of Zohak. This was crossed by Hsien Tsang in approaching India (840), and by Timur on his return (1398), and was commonly used by Babur, who calls it Shibut. There remain the Koh-i-Baba passes of Isha, Hajigak, and Pusht Hajigak. These are all approached from Chitral by the upper valley of the Chitral river and headwaters of the Hindukush. (See first Bignell's Damm's note, crossed to the west, 1840, before finding the Hindukush, and on that famous site, Baines (1832), Wood and Lord (1837), Griffith (1840), and others at that time crossed the Hajigak, the best known of the passes.) South of the mountains, the Andakab river and the Sulikab form settlements like Paurin and Ghorband rivers on the south. Unting near Ghori they join the rivers of Kunder or Alakasa (called by Babur *Daghkaba*) flowing north to the sea, crossed in 1840 before finding the Hindukush. The chief components of this section in its western portion. Further east on the north side the higher valleys are occupied by tribes of old Turkic lineage, mixed more and more with Uzbeks and other Turkic people as the Kohistan is approached (see also vol. 1 p. 241 sq.).

Geology.—Information is most scanty, and applies only to the western extremities of Hindu Kush. On the Kushan Pass Lord speaks of the lower parts as consisting of micaceous schist, black slate with occasional bursts of granite, then more slate and gneiss, and the summits of the pass and range of a granite core shooting up in piecemeal peaks. On the Koh-i-Baba, also, Griffith speaks of the lower mass as predominantly of slaty formations, the summits of coarse quartzose grey granite, and of very compact brown quartzose rock. In the Irak Pass, and at Zohak, are masses of conglomerate. Limestone occurs in the upper part of the valley of Paurin, exhibiting large cavities, in one of which the stream is engulfed for two miles, also higher up the Ghorband valley, where a magnificent natural cavern occurs. Limestone occurs also on the Hajigak Pass, and we hear of another great cavern near Domb, north of Baman. Eruptive deposits occur in Ghorband valley towards Chardak, and there occur at Baman. Huchofen has supposed, from Chinese analogies, that the multitude of artificial caves and cave dwellings about Baman indicate a loess deposit, such details as we have seem hardly to corroborate this.

The region is rich in minerals. Iron is abundant and widely diffused. Villages called *Akhangra* (of the "iron-workers") are numerous. There is a rich black ore on the Hajigak Pass, but fuel is entirely absent. Iron is also made at several places in Badakhshan, and of excellent quality in Bajaur, east of the Kunar river. The districts adjoining the four great Varday rivers are called Yangshan, which is popularly interpreted as *Hanah-Kan* ("All-Mines") from its various mineral wealth. Copper mines (not worked) exist here and also in Chitral. Antimony is found in Ghorband, and accurate Griffith speaks of ore of antimony forming boulders and even "a large mountain" on the top of Hajigak. Lead is found in Ghorband and in Yangshan.

Sulphate of zinc occurs in Ghorband, silver, as above mentioned, at the head of Panjshir, rock salt on the borders of Badakhshan and Kunduz (mentioned by Marco Polo), sulphur in Yangshan and Sangshih (north of the Dora Pass), sal ammoniac in Kurin. Opium is exported from Chitral, a fact mentioned also by Hsien Tsang. The lazuli of Kurin has been spoken of.

Zoology.—Of this we have not space to speak, nor accurate material. Afghanistan lies on the borders of the Oriental and Palaearctic regions (vol. vii p. 269), and presents in degree of both, but the Hindu Kush is to a certain extent a boundary between these. Thus it limits the genus *Salmo*, which is found in no Indian or Persian stream, but immediately on crossing the pass. The late estimable Russian traveller Fedchenko thought he had first discovered trout in Turkestan, but they were frequently caught by English officers at Baman in 1840, and Marco Polo mentions them in Badakhshan.

Vegetation.—The only basis for a view of this world be Griffith's collections near Koh-i-Baba and in the Kunar valley, but they have not been analysed in such a sense. These general remarks by Hooker and Thomson are, however, apposite.—"The collections of Griffith, besides containing an immense number of Persian and European plants which find their eastern limits within the British territory, are such in Himalayan forms as to suggest a more southern west, and, what is of still greater importance, they contain many species common both to Europe and the Himalayas, but which, from mere differences induced by local causes in these two distant countries, might not be imagined to have a common origin, did not the Afghanistan specimens blend their characters or show the transition between them."

—*Flora Indica*, i. 85, 88.

Historical Notice.—We have said that Hindu Kush is the Caucasus of Alexander's historians. It is also indicated in the Ptolemaean, though the latter term embraces more. Strabo has apparently used only when the Hindu name is in question. Whether the name was given in mere vanity to the name which Alexander pressed (as Strabo and others reportedly alleged), or was founded also on some verbal confusion, we cannot say. It was no doubt regarded (and perhaps not altogether untaken) as a part of a great alpine zone believed to unite Asia from west to east, whether called Thurus, Caucasus, or Inanus. Arrian himself applies Caucasus distinctly to the Hindu Kush. Also the application of the name Thurus to the Sin seems to indicate a real confusion with Colchian Caucasus. Alexander, after building an Alexandria at its foot (probably at Hupman, near Chitral), crossed into Bactria, first reaching Diapara, or Adipsa. This has been interpreted as Andakab, in which case he probably crossed the Khawak Pass, but the identity is uncertain. The ancient Zend name, according to Bournonville, *Parsaena*, the essential of Ptolemaean, this accounts for the great Asiatic *Parsaena* of Aristotle, and the *Pho lo-av-a* of Hsien Tsang.

The name Hindu Kush does not express, as far as we can ascertain, in any of the earlier Asia geographers. But it is used by Ibn Batuta, who crossed (c. 1332) from Andakab, and he gives the explanation of the name which, however doubtful, is still popular, at (Pan) Herakl Kulan, "because of the number of Indian slaves who perished in passing," its mounds. Babur, who calls the range Hindu Kush, and the way in which he speaks of it shows clearly that it was a range that was meant, not a solitary pass or peak (according to modern local use, as alleged by Bournonville and Baines). Probably, however, the title was confined to the section from Khawak to Koh-i-Baba (see Babur, pp. 184, 186). The name has by some later Oriental writers been modified into Hindu Ksh (mountain), but this is fictitious, and throws no more light on the origin of the title. The name seems to have become known to European geographers by the Oriental translations of the two Ptois. In the Greek, and was taken up by Delisle and D'Anville, Herodotus and Euphratesian civilisation, and Wilford Wilford about it. Baines first crossed the range (1832). A British force was stationed at Baman beyond it in 1840, with an outpost at Samsat.

The Hindu Kush, formidable as it seems, and often as it has been the limit between petty states, has hardly ever been the boundary of a considerable power. Greek, White Hun, Sarmatian, of Bactria, Ghorandus, Mongols, Hun, and Turan, down to Saddozia and Bakasas, have ruled both sides of this great alpine chain.

(H. Y.)

HINDUR, also called NALAGARRI, one of the Punjab hill states, under the government of the Punjab, India, lying between 30° 54' 30" and 31° 14' 15" N lat., and between 76° 39' and 76° 56' 45" E long. Area, 256 square miles. The country was overrun by the Ghokkas for some years prior to 1815, when they were driven out by the British, and the raj was confirmed in possession of the territories. The estimated population in 1875 was 70,000, the estimated revenue £8000, and tribute £500. The principal products are opium and the usual grains.

HINDUSTÂN. See INDIA.

HINDUSTÂNĪ, or URDŪ, is a dialect of the Hindi, one of the seven languages of Aryan stock spoken at the present day in North India, the others being the Panjabi, Sindhi, Gujarati, Marathi, Bengali, and Oriya. The area over which it is spoken in North India may be said to be co-extensive with that of the Hindi, which is estimated at about 250,000 square miles, extending from the river Ganalak in the east to the Sutlej in the west, and from the Himalays in the north to the Vindhya mountains in the south. It is also extensively used, though in a somewhat different phase, in a great part of the Deccan, and is more over the *lingua franca* of most parts of India.

As the Hindi language consists of many dialects, it is necessary to state that it is the Braj dialect, or the dialect that is spoken in the districts of Agra and Mathura, and in the neighbourhood of Delhi, the ancient capital of the Mahometan empire, which is generally regarded as the parent of Hindustani. The grammatical structure and also a vast number of the commonest vocabularies of the Braj were incorporated in the new dialect, and to these were added a vast number of Persian, Arabic, and even Turkish words. "Such words, however, in no wise altered or influenced the language itself, which, as regards its inflectional or phonetic elements, remains still a pure Aryan dialect, just as pure in the pages of Walt or Sanda, as it is in those of Tulsī Dās or Bihār Lal." Peculiarities of composition, such as reversing the positions of the governing and the governed word (*e.g.*, *bat manā ā mei ā bāp*), or of the adjective and the substantive it qualifies, or such as the use of Persian phrases with the preposition *ba* instead of the Hindi postposition of the ablative case (*e.g.*, *ba-khusht* instead of *khusht se*, or *ba-hulm* *sa-lū-ke*, instead of *sa-lū-ke hulm se*), are no doubt to be met with in many writings, and these, perhaps, combined with the too free indulgence on the part of some authors in the use of high flow and poetic Persian and Arabic words in place of common and yet distinct Hindi words, and the general use of the Persian instead of the Nagari characters, have induced some to regard Hindustani or Urdu as a language distinct from Hindi. But such a view betrays a radical misunderstanding of the whole question.

¹ Hindustani (*hi* "Of or belonging to Hindustan") is the English name for the language. The natives generally call it *Urdu* or *Urdu Zaban*, "the camp language" (the word *Urdu* meaning, in Turkish, "a camp"), and the poets, *Zibānā*, "muted," while the phrase of the dialect which is peculiar to southern India is termed *Drakani*, or "southern." The term *Urdu*, on the other hand, is derived from the Persian *Urdu*, "India," and strictly speaking, it is applicable only to the modern language of the Hindūs. The old language, prior to the invasions of the Mussalmans, is termed *Prakrit*, and is derived from Hindi. It may be added that the present article has reference only to the so-called High Hindustani, which differs considerably from the vulgar speech. This, in some parts of the area mentioned in the text, bears but little resemblance to the unrefined language, except in the possession of a few Persian or Arabic words. The High Hindustani is that which is uniformly employed in literature over the whole of the specified area. It is, moreover, the language in which the proceedings of the various Government courts and offices are carried on, and is spoken in its purity in all the large towns by the educated classes generally, by Hindūs as well as Mussalmans.

² Boames, *Comparative Grammar of the Modern Aryan Languages*, vol. i p. 32.

As regards the introduction of foreign words into the various dialects of Hindi, it seems highly probable that it had its origin at an early period, perhaps as early as the 8th or 9th century of our era. But there is good ground for the opinion that, although the Hindi area was overrun as early as the 12th century, the Hindustani was not formed till the 16th century. "For many generations after the victories of Kutub-d-din Aibak, the first Mussalman sovereign of Delhi, the conquerors retained their own Persian, and the conquered their Hindi." The Mussalmans had long been accustomed to speak pure Hindi, and it was not they who introduced Persian words into the language, but the Hindūs themselves, who at the epoch above mentioned were compelled by Todar Mal's new revenue system to learn Persian.³ And we learn from Mir Amman of Delhi (whose brief account of the origin of Urdu in the preface to his well-known *Dāgh-o-Bādh* bears on the face of it every convincing mark of probability, and scanty as it is, is remarkable as, perhaps, the only attempt at a critical discussion in the whole range of Hindustani literature) that at the date of the composition of his work (1802) the Mussalman dynasties had endured for a thousand years, and that as intercourse increased the languages of the Hindūs and Mussalmans became to a certain extent mixed. "By the arrival and stay of the Amir Timur the camp or *Urdu* of the army was introduced into the city, whence the city *Urdu* is called Urdu, a Turkish word signifying 'camp.'" "When Akbar ascended the throne, various races from all quarters, on hearing the kind patronage and bounty of that incomparable house, came and assembled in the royal presence, but the speech and dialect of each was different. From them being collected together, and owing to the trade, traffic, and intercourse which they carried on with one another, a single language, that of the Urdu (or Hindustani), was established."

The epoch of Akbar, which first saw a regular revenue system established, with toleration and a free scope for their religion granted to the Hindūs, was, there can be little doubt, the period of the formation of the language. But its final consolidation did not take place till the reign of Shah Jahān. After the date of this monarch the changes are comparatively unimportant until we come to the time when European sources began to mingle with those of the East. Of the contributions from these sources there is little to say. Like the greater part of those from the Arabic and Persian, they are chiefly nouns, and may be regarded rather as excrescences which have sprung up casually and have attached themselves to the original trunk than ingredients fully incorporated in the body. In the case of the Persian and Arabic element, indeed, we do find not a few instances in which nouns have been furnished with a Hindi termination, *e.g.*, *kharānā*, *badānā*, *ghasnā*, *dāghnā*, *bat-havnā*, *kamināpan*, &c. But the European element cannot be said to have at all woven itself into the grammar of the language. It consists, as has been observed, solely of nouns, principally substantive nouns, which on their admission into the language are spelt phonetically, or according to the corrupt pronunciation they receive in the mouths of the natives, and are declined like the indigenous nouns by means of the usual postpositions or case affixes.⁴ A few examples will suffice. The Portuguese, the first in order of seniority, contributes a few words, *as kamārā* or *kamā* (cannery), "a room," *mātrik*, "a hammer," *nādmā*, "anation" (often corrupted

³ Boames, *ibid.* vol. i p. 30, note.

⁴ It is supposed, however, that the strange dialect in which the London, or "native sermon," and the Dhilli, or "hotness," hold converse, and in which orders are given to a native crew repeating the wailing of a ship, is compounded of Portuguese words assimilated to Hindustani in their terminations and inflections. Of this there is no positive proof, and until the matter has been properly and satisfactorily investigated it would be injudicious to pronounce a decided opinion.

into *hūṣm*), *peṣā*, "a turkey," &c &c Of French and Dutch influence scarcely a trace exists. English has contributed a number of words, some of which have even found a place in the literature of the language, e.g., *Kammushan* (commissioner), *jaṣ* (judge), *isānt* (assistant), *dāltā* (doctor), *dāltā*, "the science of medicine," or "the profession of physicians," *inspeltā* (inspector), *soṣayāt* (society), *apūl* (appeal), *apūl lānā*, "to appeal," *dikr* or *dygr* (decree), *dygr* (degree), *nuh* (moh), *fuṭ* (foot), and many more, are words now commonly used. How far the free use of Anglicisms will be adopted as the language progresses is a question upon which it would be hazardous to pronounce an opinion.

The grammatical structure of the Hindustānī differs in no essential particular from that of the Hindi from which it is sprung. It is therefore of the rise and formation of this language, and of the stage to which it had attained when the new phase of the Hindustānī was developed from it, that we shall now speak.

Of the history and development of the Hindi or Hindū language previous to the 11th century of our era little or nothing is known. It is accepted as a fact by most scholars that Sanskrit ceased to be a vernacular in the 6th century B.C., when the Buddhist religion was founded, which for ten centuries drove Brahmanism into obscurity. From that time the Aryan people of India spoke popular dialects called Prakrits,¹ and it is from these that the modern Aryan tongues are mainly derived. These Prakrit dialects are generally grouped under five heads, viz., the Mahārāṣṭrī, Sauraseni, Māgadhī, Pūncālī, and Apabhraṃsa. Of these the Sauraseni, or dialect of Sauraseni, the modern tract of Mathurā and the surrounding country, is taken to be the parent of the Hindi, or at any rate of that phase of it with which we have to do. These Prakrits were, like the Sanskrit, syntactical and inflexional in their structure, and certainly continued to be so up to the 1st century of our era, the lowest stage to which in point of development scholars have been able to reach. At what precise period the syntactical structure of the Prakrit began to break up and to give place to the analytical formations of the modern speech it is impossible to tell. The gap of nine centuries has yet to be filled up. And unless future discoveries of Buddhist literature should shed light on the subject, it is to be feared that the history of this period will even remain unknown.

The dawn of modern Hindi may be dated from the 11th century. The earliest known writer in the language was Chānd Baidā (c. 1200), whose eye is in a dialect rule and half-formed, but as decidedly analytical as the Hindi of the present day.² Much of the old syntactical structure no doubt is still to be found in the work, the particles and the auxiliary verbs are in a very crude and unformed state (as, for example, the use of an obscure *la* for the modern genitive affix *kā*, which *ka* does not vary with the governed noun, and is frequently left out altogether, the total absence of the ordinary substantive verb *has*, &c.), but these crudities and remnants of old Prakrit forms do not affect the general structure. Indeed, they are to be found in writings of a much later period, in works belonging to the 14th and 15th centuries, e.g., in the *dhā*.

¹ Prakrit is derived from the Sanskrit *prākṛit*, "native," and signifies "natural," "not accomplished," "vulgar." It is the old name of those dialects which are immediately derived from, which stand in an immediate relation to, Sanskrit, or "the polished or accomplished language" of the Hindus.

² It is this striking change from the syntactical structure of the Prakrit to the analytical of the Hindi, coupled with an accidental resemblance in certain of the case affixes to those of the Dravidian tongue, that has led some Oriental scholars to claim for Hindi a non-Aryan descent. But this view is ably controverted by Mr. Beames in his *Compendious Grammar of the Aryan Languages of India*, and by Professor Rudolf Hoernle, in his *Essays on the Gaurian Languages*.

Griṣṭh, the language of which exhibits, according to Trumpp, "6,000 metrical forms not firmly fixed, but rather in a state of transition." And although the forms assume greater fixity, and marked progress is observable in the works of later writers in the Bīj Blāṣhā dialect, e.g., in those of Kabī, Sūr Dās, Nabhā Jī, Kcavā Dā, and Bihārī Lal (whose poems are, as a rule, composed in very pure and elegant Hindi), we still find certain crudities and traces of Prakrit forms and organic structure, and these continue even in the language of the present day.

To give a minute account of the grammatical formation, to indicate the various phonetic or glottic laws by the operation of which the vocabularies and grammatical forms of the Hindi are derived from those of the Prakrit or Sanskrit, is beyond the scope of the present article. We can but notice a few general laws, and exhibit results, so far as they have been ascertained. For closer acquaintance with the subject we must refer the reader to the *Pāṭiśi* of Pāṭiśi of Varanasi, edited by Professor E. B. Cowell, the *Pāṭiśi Grammar* of Hemachandra, edited by Professor Pischel, the *Compendious Grammar of the Modern Aryan Languages of India*, by John Beames, B.C.S., and *Essays on the Gaurian Languages*, by Professor Rudolf Hoernle.

Prakrit tolerates no compound consonant in the beginning, and no dissimilar consonant in the middle of a word. Two dissimilar consonants in Sanskrit were changed in Prakrit to two similar consonants, and occasionally one of these is elided and the preceding vowel lengthened. In the modern dialects this elision of one consonant and compensatory lengthening of the preceding vowel is the rule. Prakrit either changes a medial short mute consonant to the corresponding sonantone, or elides it altogether, and it generally changes an aspirate mute consonant to the simple aspirate *h*. In fact the modern Aryan tongues stand to the Prakrit and the Sanskrit in a relation very similar to that existing between the Italian, &c., and the Romance and Latin languages. Hindi "is not the daughter of Sanskrit, as we find it in the Vedas, or in the later literature of the Brahman, it is a branch of the living speech of India, springing from the same stem from which Sanskrit sprang when it first assumed its literary independence."³

³ *Vocables*—The vocables may be grouped under three heads—1. Words which are pure Sanskrit, as *īṣṭā*, "a king," *puṣṭ*, "fatten," *kām*, "a poet," *adga*, "a cow belonging to a city," *lāma*, *lāya*, "work," *lōdha* (vulg. *lōdh*), "anger." Not a few of this class of words have existed in the language for some centuries, some are to be found even in the oldest specimens of the literature that by the large number in Sanskrit have been taken into the present century, and the introduction is still progressing. The form in which they appear is that of the Sanskrit nominative singular.

2. Words which are derived from the Prakrit, and have been considerably changed in the process, though not so much as to obscure their origin, e.g., *kām*, "work," *Pik lamma*, *S kama*, *kām*, "cow," *Pik kama*, *S kama*, *adh*, "night," *Pik althā*, *S althā*, *hāth*, "hand," *Pik hāthā*, *S hāstā*, *āṣ*, "salt," *Pik appā*, *S āmā*, *bāt*, "word," *Pik vāṭhā*, *S vāṭhā*, *āṣ*, "to day," *Pik āṣṭā*, *S āṣṭā*, *āṣ*, "before," *Pik āṣṭā*, *S āṣṭā*, *āṣ*, "husband," *Pik āṣṭā*, *S āṣṭā*, "work," *Pik vāṭhā*, *S vāṭhā*, *phāṭṭā*, "Fcb-March," *Pik phāṭṭā*, *S phāṭṭā*, *buddhā*, "old," *Pik vāṭhā*, *S vāṭhā*, *kāṭhā*, "sail," (Hing *kāṭhā*), *Pik kāṭhā*, *S kāṭhā*, "sail," (Hing *kāṭhā*), *Pik rāṭhā*, *S rāṭhā*, *thā*, "was," *Pik thā*, *S althā*. This is by far the largest class of words in the Hindi. And, as in the case of the first class, they are adopted in the form of the nouns native analogies of the Prakrit. They are divisible into two classes, the first comprising such as have in their declension preserved traces of the old organic inflexion of the Prakrit declension, and the second those which have preserved no such traces. As regards these it may be observed that the terminations *ā*, *ī*, *u*, *ī*, *ū*, of the Prakrit, are regularly reduced in the Hindi to their inherent simple vowels, *ī*, *ā*, *ī*, *ū*, *ā*, *ī*, *ū*, and *ā*, *ī*, *ū*, and *ā*, *ī*, *ū*, and these short vowels are, as a rule, made quiescent, so that a word ending in reality as a short vowel virtually terminates in a consonant, and not being pronounced, the final short vowel is frequently suppressed in writing also.

³ Max Müller, *Lectures on the Science of Language*, lect. xi.

ception of a fragment by Jaidoo (the author of the Sanskrit *Gita Govinda*), preserved in the *Adi-Granth*, the oldest specimen of Hindi which we possess; but it is impossible to suppose that he was the first to attempt poetical composition in that language. The metrical perfection of his verse alone shows that he must have had many predecessors, and rude and rough though his utterance is, it abounds in poetic conventionalisms which must have been the common stock of many singers of his class. The story is told in sixty-nine books, of which some are interludes and digressions, but most are occupied with the exploits of the hero and his warriors. Considering the early date of the poem, and the opportunities of knowing the truth which the author (if he was really Prithviraj's bard) possessed, it is remarkable how much legend and fiction is mixed up with history in the chronicle. The repeated conflicts between the Rajā and Sultan Shihabuddin of Ghori, in which the latter always, except in the last great battle, comes off the worst, and is released on payment of a ransom, seem to be entirely unhistorical, our authorities knowing only one encounter (that of Tiraut near Thanesar, fought in 1191) in which the sultan was defeated, and there even he escaped unaptured to Lahore. The Mughals (Book xv) are brought on the stage more than thirty years before they actually set foot in India (1233), and are related to have been vanquished by the redoubtable Prithviraj. These and other points make it questionable whether we have here, at least in its entirety, a genuine contemporary work, but we may concede, as indeed we are justified in doing by the language of the poem, that it is one of our earliest documents in Hindi.

It is very difficult for us now to form a just estimate of Chandi's poem the language, essentially transitional in character, abounds in strange forms which have long since died out of the vernacular speech, few if any Hindus, even the most learned, are able to interpret him, and his meaning must be sought by investigating the pictures by which Sanskrit and Pālikt words have been transmuted in their progress into Hindi. But upon the whole he may be said to exhibit both the merits and defects of ballad chroniclers in general. There is much that is lively and spirited in his descriptions of fight or council, and the characters of the Rajput warriors who surround his hero are not infrequently sketched in their own words with skill and animation. The sound, however, too often predominates over the sense, and we find abundantly exemplified in his poem the wearisome iteration, un inventive sameness of machinery, and tedious unfolding of familiar themes and images which distinguish nearly the whole of Indian narrative poetry. His value, for us at least, is linguistic rather than literary.

The other class of composition which is characteristic of the period of Old Hindi, the literature of the *Bhagvats*, both possesses more intrinsic interest and has exercised a more important influence on subsequent literary endeavour. The heroic chronicles, with perhaps the single exception of a famous saga relating the history of Padmāvatī, wife of Ratan Sen Rajā of Chitor, who in 1303 at the taking of that fortress by Sultan 'Alā' ud din burnt herself and (so says the tale) 13,000 other women rather than fall into the hands of the conqueror, which has been several times handled by poets outside the pale of Rajput traditions, and especially in a still highly esteemed work by Jaiu under Sher Shah (1540), had only a local currency, and contributed but little to the furtherance of literature outside the limits of Rājasthān. The Vaishnava reformers, on the other hand, exercised the most powerful influence both upon the national speech and upon the themes chosen for poetic treatment. Nearly the whole of subsequent Hindi literature is impregnated with one or

other form of Vaishnava doctrine, a very large proportion of the poets whose works are still current among the people were Vaishnava saints or *bhagats*, and to their initiative is due the almost exclusive use as a poetic dialect of that form of archaic Hindi known as *Diya bhākha*. Vaishnavism was essentially a reaction against Brahmanical influence and the chains of caste, a claim for the rights of humanity against the monopoly which the "twice-born" asserted of learning, of worship, of righteousness. As Śiva was the peculiar deity of the Brahmins, so was Viṣṇu of the people, and while the literature of the Śarvas and Śāktas is almost entirely in Sanskrit, and exercised little or no influence on the popular mind, that of the Vaishnavas is mainly in Hindi, and in itself constitutes the great bulk of what has been written in that language.

The Vaishnava doctrine is commonly carried back to Rāmānuja, whose appearance is placed by Wilson about the middle of the 12th century. He was a native of Southern India, and had few immediate followers in the north. In the latter region the new opinions were spread by Rāmānand, whom the *Dhātāmālā* makes the fourth head of the sect, and other authorities the fifth. Both Wilson and Trumpp place him about 1400 of our era. Nothing in Hindi by Rāmānuja has come down to us, of Rāmānand we have one short poem in the *Granth* (Introduction, p. cxiv). Between Rāmānuja and Rāmānand (though not in the line of teachers descending direct from the former) we may place Jaidoo (about 1260) and Nāmdoo (about 1300), of the first of whom we have a fragment in the *Granth*, and of the second six pieces have been similarly preserved. Jaidoo was a Brahman, and well acquainted with Sanskrit, but Nāmdoo (or Nāmā) was a *chētyā* or caste painter, a very despised class, and was perhaps the first to proclaim among the followers of the new doctrine the essential unity of mankind as worshippers of Hari. Kābi comes next, and is incomparably the greatest, in the order of Vaishnava teachers. He was a wāvri by caste, and in all probability originally a Muslim. He is counted among the twelve disciples of Rāmānand, but he seems himself to trace his spiritual paternity rather to Jaidoo and Nāmā.¹ He dwelt first at Benares and afterwards at Maghar, in the present district of Gorakhpur, during the reign of Sikandar Lohi Lodī (1488-1517), and was probably dead before the end of the 15th century. Nāmā, the first Gurm of the Sikhs, whose *Granth* is little more than a paraphrase of Kābi's writings, was born in 1489 and died in 1538, and from the relation between the two it seems necessary to suppose that Kābi was several years the senior.

The works attributed to Kābi are very numerous, they are preserved almost all at the headquarters of the sect, the *Kābi chavā* at Benares, and many portions of them have been separately printed and lithographed in India. The best known are those entitled the *Sākhī*, *Sāda*, and *Rekhar*, which have a wide popularity even among those who are not professed disciples of the saint. Several of the compositions enumerated under the name of Kābi are, however, not by him, but by his disciples as the lesser *Bhāg*, by Bhāgo-Dās, the *Sākh-Nūkhān*, by Sant-Gopal, &c., it was the custom (as also that of Kābi's religious heirs, the Sikh Gurus) for the successors in the guruship to speak in the name of him whose successors they were. The doctrine of Kābi is

¹ This may be concluded from a short poem in the *Granth* (p. 460), where Kābi says (verses 4, 5) — "Let each one seek the Lord, O brother when the body falls away, where shall the Mind be absorbed? By the favour of the Guru Jaidoo and Nāmā through the loss of Faith attain to knowledge of Him" (*The Mind is the underlying Eternity, divine, pervades all*).

² A tolerably full account will be found in II. H. Wilson's *Lectures on the Religious Sects of the Hindus* (Works, vol. 1 pp. 68 sqq.), Dr. Trumpp's *Essay on the Religion of the Sikhs* (*Granth*, Introd., pp. xxvi sqq.) may also be consulted.

was philosophically a form of pantheism, accounting for the existence of phenomena (the reality of which was denied) by the agency of a *Māya*, or illusion, emanating from the Supreme. The varied lot of men in life, their differences of faith and aim, their desires, fears, hopes, loves, are all the work of this *Māya*, to know which, and to recognize beneath all the Supreme, is the only means of emancipation from the chains of illusion. Neither austerities, ritual, nor works of any kind are necessary to obtain the highest end, this is only to be gained by *bhakti*, "faith," and poetical meditation on the Supreme—His name, *Hari*, *Rām*, *Govind*, being ever on the lips and in the heart. The highest end is absorption in the Supreme, reunion with Him from whom all proceeded and who exists in all. Little place is left in this somewhat barren doctrine for a social code, since works are naught, but negatively, at least, it is inoffensive, commanding respect for all forms of life, and quiet performance of duty without self-seeking or desire for gain.

Of the spiritual followers of Kabir many have left memorials in literature, one of the most eminent of these was Dādī, founder of a sect very prevalent in Rājpūtānā. A translation of two chapters from the *Granth* or scripture of this *Bhagat* will be found in a note to Wilson's *Religious Sects of the Hindus*, pp. 106-113, and will repay perusal. But those whose compositions, if not most excellent from a literary point of view, have of any rate wrought most in history, were the Gurus or spiritual heads of the Sikhs of the Panjāb. The *Adis Granth*, or Book of the first five Gurus (from Nanak, who died in 1538, to Arjun, who died in 1601), is described by its translator as "perhaps the most shallow and empty book that exists, in proportion to its size," and certainly the translation is not attractive reading. But the doctrine, reiterated with the most painful diffuseness, are essentially those of Kabir, much of whose writings has been incorporated in the volume. The language is rather Old Hindi than Old Panjābi, and thus the work falls within the scope of this article, though Panjābi words and idioms frequently occur, the grammar is Hindi, and the authors evidently aimed at propagating their tenets rather among the Hindi-speaking races of Hindustan proper than (as actually happened) among the Panjābi-speaking tribes of the West and South-West. The *Granth* consists of six parts. I, the *Japī*, the only portion as yet published in Europe in the original Hindi, II, III, and IV, arrangements for devotional purposes of extracts from Part V, the *Rāgs* or body of the *Granth*, of these *Rāgs* there are thirty-one, but only four, *Sri Rāg*, *Māh*, *Gaurī*, and *Asā*, have been rendered by Tāmp, the remaining twenty-seven are described as "a second gathering or gleaming, as materials offered themselves, no attention being paid to the contents, but only to the bulky size of the *Granth*," VI, the *Bhag* or conclusion, containing verses by various authors, among them Kabir and Sheikh Faiz of Pakpattan, a famous Indian *Sūfi*, and panegyrics of the five Gurus, by fifteen *bhakti* or bardas. At the end of each *Rāg* is a collection of sayings of the *Bhagat*, chiefly of Kabir, in confirmation of the doctrines set forth by the Gurus, and it is in these additions that the literary importance of the work, as a treasure of specimens of early Hindi, mainly consists.

Another of the following of Rāmānand, though considerably later in time than Kabir, was Sū-Dās. Of his life little is known, as some of his verses are included in the *Granth*, he must have lived before its redaction (about 1600), if he be the same as a saint of that name mentioned in the *Bhaktamālā*, as is probable, he was a Brahman, *amīn* or revenue collector of the *pargana* of Sandilā in Oudh during the reign of Akbar, who is related to have appropriated the collections of his district for the service of the

temple of Madan-Mohan at Bāndāban, sending to the treasury instead chests filled with stones. When his delinquency was discovered, he was pardoned by Akbar, but thenceforth abandoned the world, and, becoming blind, led a wandering life as a singer of the praises of Vishnu. His stanzas, generally of four lines (*padas*), are said to number no less than 125,000, they are collected in a huge volume entitled the *Sū-Rāga*, and are extremely popular.

While the sects of which Rāmānand may be considered the spiritual father adore the Deity chiefly under the names of *Rāma*, *Hari*, *Govind*, and dwell but little on the *avatāra* or human incarnations of the Hindu god whom they have selected as the type of the Supreme, there is another division of the Vaishnavas which is not less important in Hindi of authorship, and counts its adherents by millions, whose worship is of a different character. The sects belonging to this division take Krishna as their favourite type of the godhead, and, accepting the whole mass of legends (most of them probably of comparatively late origin) relating to this incarnation, inspire themselves with fervour by the contemplation chiefly of Krishna's childhood and his youth in the society of the herd maidens of Brāj. As the doctrine and object of worship are, so also is the mode of life. The Rāmānandis are for the most part men of ascetic and unworldly life, not indeed given to self-torture or needless austerities, but earning nothing for the wealth of the world, and living quietly and soberly in the possession of what they deem the truth. The worshippers of Krishna and his mistress Rādhā, or of the infant Bāl-Gopal, on the other hand, are no ascetics, but persons of luxurious and often opulent lives, among women especially this form of devotion is widespread. The chief sect of this denomination is the *Vallabhāchārī*, or, the following of the *Golābāthā Gosāthi*. Their founder was one Vallabha Svāmī, a Brahman from the south, who settled at Gokul near Mathurā, probably about the beginning of the 16th century. The best known works of this sect are the *Brāj-bāla*, a description of Krishna's sports with the maidens of Bāndāban by Brāj-bāla-Dās, and the *Vaṇitā*, a collection of legends regarding eighty-four teachers of the following, resembling the *Bhaktamālā*, which deals chiefly with the other division of Vaishnavas. The popularity of the *Brāj-bālas* is immense, and it is to be found in a lithographed form for sale in every bazar. Its contents (as indeed many other productions of the worshippers of Krishna) have been condemned by Europeans as indecent, but although containing much that seems at least outwardly lewd and impure, it is a work the study of which is indispensable to one who would understand the religious temper of the Hindus. The mystic dwelling on the amours of Krishna and the *Gopīs* of Brāj has been often compared to the mystical interpretation of the *Song of Solomon*, and in most religions we shall perhaps find at least one phase in which the sensual is curiously mingled with the spiritual, and faith and love towards the heavenly stimulated by thoughts and phrases drawn from earthly scenes of passion. Of the *Vaṇitā* we shall speak under the next division of our subject.

2 Middle Hindi reaches from about 1570 to 1750. To this age belong the best poets of Hindi literature, Keshv-Dās, Balarāi Lal, and Tulsi-Dās, whose writings are no less remarkable for skill and subtlety of language than for perfection of metrical form. The labours of their predecessors had wrought the language of western Hindustan into a medium worthy of being put to the highest poetic use, and we accordingly find in the poets of this period large borrowings from Brāj, even where (as with Tulsi-Dās) that idiom is not the dialect of their own region. From their day onward Brāj-bhāshā has been esteemed (in the words of Lalāi-Lāl) "the standard language of sentiment

(*nāḥāi use-māli*), and equal to the speech of the gods" (i e., Sanskrit).

Kesav Dās was a Brahman who lived under Jahāngīr and Shahjāh in . He was the author of a poem on Ilamā, entitled the *Rāmānandāśītā*, written in 1603, the *Kumār-pyā*, written in the same year, a treatise on the poetic art of much celebrity, the *Rasik-prayā*, on rhetoric, written in 1593, the *Bhaktatīlāmā*, an exposition of the doctrine of Rāmānandī Vaiṣṇavism, and several other works. Kesav Dās's compositions are widely popular, and have been frequently lithographed in Northern India.

Bihārī Lal is renowned as the author of the *Sat saṭ*, a collection of 700 distichs, which is perhaps the most celebrated work of Hindi poetic art, as distinguished from narrative and simpler styles. They are inspired by the Kṛishṇa side of Vishṇu-worship, and take the form of amorous dialogues between Rādhā and the other *Gopīs* and their lover. The author was a native of Gokūlyār, and lived at Ambā during the early part of the 17th century. Editions of this work, one of the most difficult in Hindi and abounding in subtle conceits, are very numerous. It has been commented on by a crowd of scholars, among them, strange to say, more than one Musalman,—a sufficient proof of the value set by natives of India, irrespective of their creed, on its perfection of language. It has even been translated into Sanskrit.

Tulsi-Dās, though perhaps inferior in poetic skill to the two last mentioned, is undoubtedly the most popular Hindi poet. His *Rāmāyan* (originally named by the author *Rām-chait-anandya*, or "the Lake of Rām's deeds") is perhaps better known among Hindus in Upper India than the Bible among the rustic population of England. He was a Kānaujī Brahman, and probably (from his language) a native of Oudh. The greater part of his life he spent at Benares, he died in 1631. His *Rāmāyan* was commenced at Ayodhyā in 1573. Besides this great work, he is the author of six other poems, all bearing more or less on the history and worship of Ilamā, called the *Rām dūtavāt*, the *Dohavāt*, the *Kāśī sambandh*, the *Jauney-pyāśītā*, the *Pad-Rāmāyan*, and the *Ohāndāśītā*. Seven other minor works are attributed to him, but their authenticity is doubtful.

Tulsi's *Rāmāyan* is a rehashing of the great theme of Vālmiki, but in no sense a translation of the Sanskrit poem, real translations are scarcely to be found in original Hindi literature, the vernacular author, permitting themselves great liberty of excision, adaptation, and addition. It consists of seven books, of which the first two, called the *Bāl kāvī* and *Ayodhyā kāvī*, make up more than half the work, and relate the birth and boyhood of Rāma and his brethren, his marriage with Sītā, then dwelling together in the forest, her abduction by Rāvan, the expedition to Lanka and the overthrow of the ravisher, and the life at Ayodhyā after the return of the reunited pair. It is written chiefly in *dohās*, *soṭahās*, and *chāpūṭīs*, with here and there a *āhāṇ* interspersed; the style is very even and well sustained, and the language, while fundamentally the Old Pūbi of eastern Hindustan, borrows largely from Brāj. The most admired portion of the work is the second book, *Ayodhyā*, which tells of the mischief wrought by Kaikeyī, one of the queens of Dasarath, Rām's father, who had bound himself by a vow to grant her what boon she should ask, and whom by this bond she compelled to command Rāma and Sītā to go into exile in the great forest north of the Jumna, and to give the throne to her own son Bharat. In this trouble Dasarath dies, and his son obediently goes forth with his wife and his brother Lachhman to the southern wilderness. The sorrow of Dasarath, the sweet filial piety and perfect manhood of the divine Rāma, the valour and prompt affection of Lachhman, the sincerity and humility of Bharat, the purity and wifely obedience of Sītā, are

themes which a Hindu reader is never tired of dwelling upon in Tulsi's pages. And unlike though the treatment be to our own standards of taste, overgrown with theological digressions and explanations, and stocked with conventional images and stereotyped phrases as the poem is, even a European may find in it something of literary achievement which appeals to him, however distantly, as the work of a master of the heart. The first two books of the *Rāmāyan* have been admirably rendered into English prose by Mr F S Growse (Allahabad, 1877-78).

Tulsi, though essentially a Hindu and a Brahman in religious feeling, yet belongs to the class of Vaiṣṇavas who count among them Rāmānand and Kabī. He has little or nothing of the sensual passion of the devotees of Kṛishṇa and Rādhā, and in the commentary on the *Bhaktamālā* it is related that, when in his old age he paid a visit to Brindāvan, the centre of the Kṛishṇa-cult, he refused to render homage to any other form of the god than Rāma. According to the legend, he was beguiled into a temple of Kṛishṇa, and bidden there to worship Rāma, he answered that he would only bow his head before one who should bow in his hand the bow and arrows of the king of Ayodhyā, hearing his speech, the image of the god, standing still then as Kṛishṇa with the flute (*Bendulāl*), suddenly changed to the similitude of Rāma with the bow.

The *Bhaktamālā*, or "Roll of the *Bhāgavats*," a collection of the devotional songs called *Doms* or *Domās*, who lived during the reign of Jahāngīr, and was a contemporary of Tulsi Dās. The *Bhaktamālā*, in the form in which it is commonly met with, consists of a *māl*, or original text, ascribed to Nābhājī, and a *rīkā*, or commentary, of which there are two, due respectively to Kṛishṇa Dās and Prīya-Dās, both stated to have been written in 1713, in verse, and many more in prose. The *māl* is a short *stāvan* (*chhappas*) for each saint, the first line of which is repeated again at the end, stating, in the briefest and most obscure language, his characteristics. The original work of Nābhājī was amplified and added to by Nanyān-Dās, who lived during the reign of Shahjāh. Mr Growse justly says of it—"The style (of the *māl*) might be described as of unparalleled obscurity, were it not that each separate portion of the text is followed by a *rīkā*, or gloss, in which confusion is still worse confounded by a series of the most disjointed and inept allusions to different legendary events in the saint's life." A considerable portion of the *Bhaktamālā* was printed in 1817 in Major Price's *Hindu and Hindustani Selections*, and it has been largely drawn upon by Wilson in his account of the religious sects of the Hindus. The saints treated in it are chiefly of the class of Vaiṣṇavas addicted to the worship of Rāma, and the anecdotes of them contained in the work are generally meagre and extravagant in the extreme. "Such as it is, however, it exercises a powerful influence in Upper India on popular belief, and holds a similar place in the superstitions of this country to that which was occupied, in the darkest ages of the Roman Catholic faith, by the *Golden Legend* and *Acts of the Saints*" (Wilson).

The other side of Vaiṣṇavism, that devoted to the cult of the infant or youthful Kṛishṇa, with or without his mistress Rādhā, is represented by a work similar in character to the *Bhaktamālā*, called the *Vāṭṭā*, or *Chaurās Vāṭṭā*, already mentioned. Specimens of its contents will be found in Wilson's *Religious Sects of the Hindus*, p 132. Its legends are of the most trivial and childish description, but, with the tenth chapter of the *Bhāgavata Prāśna*, rendered into Brāj bhāṣā by Chāṭanbhū Mīśra, and into modern Hindi in 1804-10 by Lalā Lāl, they are nevertheless the inspirers of the greater part of the popular worship throughout the whole of Northern India. The universality

of the cult of the infant Krishna may be judged by the enormous number of Hindu proper names which end in *Lak*, meaning "child," all of which embody some reference to this deity in his youthful form. In Bengal especially the sect is extremely numerous, having there arisen out of the teaching of Chaitanya, who is said to have married a daughter of Vallabhaclayaya, and is believed by his followers to have been himself an incarnation of Krishna.

Such, in the briefest outline, is the character of Hindi literature during the period when it grew and flourished through its own original forces. Founded by a popular impulse in many respects similar to that which gave rise to Buddhism nearly 2000 years before, and cultivated chiefly (though by no means exclusively) by authors not belonging to the Brahminical order, it was the legitimate descendant in spirit, as Hindi is the legitimate descendant in speech, of the Prakrit literature which preceded it. Entirely in verse, it adopted and elaborated the Prakrit metrical forms, and carried them to a pitch of perfection which is too often overlooked by those who concern themselves rather with the substance than with the form of the works they study. The language of these compositions strikes us often as rude, abrupt, and ambiguous, undoubtedly in its earlier specimens it is wanting in clearness and definiteness of grammatical form, but the slackness of metre is frequently the explanation of unusual forms of speech, and the necessity of hitting out a metrical scheme led in too many cases to inequalities and amplifications which had perhaps no representatives in the uncompelled utterances of the vernacular tongue. Interesting when regarded in the mass, its attractions in detail are few. As in all Oriental literatures, repetition and shallowness of idea overcomes it, and render an extensive course of reading intolerable to a European. Conventional images, platitudes exalted to the utmost degree of clarity, banal philosophical and theological themes which in their wideness entirely overlook the study of detail,—such are, with few exceptions, its leading features, and one who has read two of these books has in truth made himself master of the whole secret of original Hindi literature.

3. The *origines* of Urdu as a literary language are extremely obscure. The popular account refers its rise to the time of Tmir (1398). Some authors even claim for it a higher antiquity, asserting that a *divan*, or collection of poems, was composed in *Ilekhtak* by Mas'ud, son of Sa'd, in the last half of the 11th and beginning of the 12th century, and that Sa'd of Shiraz and his friend Amir Khusrav of Delhi likewise made verses in that dialect before the end of the 13th century. This, however, is very questionable, and the better opinion appears to be that these ancient compositions, if they existed at all, were written in Hindi according to the metrical forms of that language, rather than in what is properly called Urdu. That Muhammadans composed in Hindi, and used that language as their vernacular, is certain, and in many passages of Kalir, which are nevertheless pure Hindi compositions, Persian words are used almost as freely as in the modern dialect. Much of the confusion which besets the subject is due to the want of a clear definition of what Urdu, as opposed to Hindi, really is.

Urdu, as a literary language, differs from Hindi rather in its form than in its substance. The really vital point of difference, that in which Hindi and Urdu are incommensurable, is the prosody. Hardly one of the metres taken over by Urdu poets from Persian agrees with those used in Hindi; in the latter language, it is the rule to give the short *a* inherent in every consonant or group of consonants its full value in scansion, except occasionally at the metrical pause. In Urdu this is never done, the only somewhat analogous rule providing for the enunciation of a short *a*

(the *an-fatha*) after a nexus of consonants which would otherwise be pronounced without it, the great majority of Hindi metres are counted by the number of syllabic instants or *matras* (the value in time of a short syllable) in Urdu the metres follow a special order of long and shorts.

The question, then, is not—When did Persian first become intermixed with Hindi in the literary speech?—for this process began with the first entry of Muslim conquerors into India, and continued for centuries before a line of Urdu was composed,—nor, When was the Persian character first employed to write Hindi?—for the written form is but a subordinate matter. We must ask—When was the first verse composed in Hindi, whether with or without foreign admixture, according to the forms of Persian prosody and not in those of the indigenous metrical system? Then, and not till then, did Urdu come into being. If, then, it is really the case that poems were so composed as early as the 11th or the 13th century, the origin of Urdu literature must be carried back to that period. But Hindi itself was at that date, and for many decades later (as we see from Chand and our other earliest specimens of the language), in an unsettled and transition stage. Neither in its case inflexions nor in its verbal forms did it resemble the language which we know as Urdu. It abounded in short vowels and hiatuses, which could not accommodate themselves either to the Persian character (without the free use of vowel signs and *hamzas*, which were seldom employed) or to Persian prosody, and its syntactical order was loose and unsettled. Urdu, as we know it, is the Hindi of the end of the 16th century enriched from Persian, not the Hindi of Chand and the early *Bhagats*.

The whole of Urdu poetry follows Persian models of composition, its themes are those which had already been worked (some might say, worked out) by writers in that language, and neither in form nor substance do we find the faintest flavour of originality from its commencement to the present day.

The paucity of themes and want of originality in Urdu verse has led to a most elaborate development of the system of rhetoric. Where the substance of what a poet has to say is identical with that which has been said by hundreds, nay thousands, of poets before him, it is of the highest importance that the way of saying it shall if possible be peculiar to himself. Rhetoric, accordingly, rather than poetic feeling, is the distinguishing feature of composition in Urdu. Pleading hyperbole, ingenious comparison, antithesis, alliteration, carefully arranged gradation of noun and epithet, are the means employed to obtain variety, and few of the most eloquent passages of Urdu verse admit of translation into any other language without losing that which in the original makes their whole charm. Even in the *masnavis*, or narrative poems, the story is usually quite a subordinate matter, it has in most cases been handled time after time, and is familiar to the reader in its minutest detail. Even when the names chosen for the actors are new, the intrigue is old, and the mode in which it is unfolded is the only thing which distinguishes one poem from another. The descriptions thus, confined within a narrow circle of incident and epithet, repeat each other with a monotony which to a European is unexpressly fatiguing, but which in the East is deemed rather a merit than a defect. Differences of school, which are made much of by native critics, are to us hardly perceptible, they consist in the use of one or other range of metaphor and comparison, clasped, according as they repeat the well-worn poetical stock-in-trade of the Persians or seek a slightly fresher and more Indian field of sentiment, as the old or the new style of composition.

These being the nature and features of Urdu poetry, it will be manifest that such an account of it as can

Dehli (died 1839), was under the name of Zafar, and was a pupil in poetry of Shukh Ibrahim Zang, a distinguished writer; he has left a voluminous *divan*, which has been printed at Delhi. Mirhat (Ghulam Hamid), who died about 1814, was one of the most distinguished of the several poetic school of Delhi, and was himself one of its founders. Originally of Lakhnau, he left that city for Delhi in 1777, and held conferences of poets, at which several authors who afterwards acquired repute formed their style, he has left five *diwans*, a *masnaw*, and a biography of Urdu poets, and a *Shah-namah* or account of the kings of Delhi down to Shah 'Alam Qam (Qayamuddin 'Ali) was one of his society, and died in 1792, he has left several works of merit. Gulib, otherwise Mirza Asadullah Khan Nizamat, laureate of the last Mughal, who died in 1839, is undoubtedly the most eminent of the modern Delhi poets. His work chiefly in Persian, of which language, especially in the form cultivated by Firdausi, lies from intermixture of Arabic words, he was a master, but his Urdu *divan*, though short, is excellent in its way, and his reputation was spread far and wide. To this school, though he lived and died at Agra, may be attributed Mir Wali Muhammad Nair (recently died in 1882), his *masnaw* entitled *Jagi-namah*, *Kasur-namah*, *Branghi-namah*, and *Bur-hay-namah*, as well as his *diwans*, have been frequently reprinted, and are extremely popular. His language is less artificial than that of the generality of Urdu poets, and some of his poems have been reprinted in Káshmir, and are all known and as much esteemed by Hindus as by Muhammadans.

4 While such, in outline, is the history of the poetic schools of the Dakkhin, Delhi, and Lakhnau, a fourth, that of the Fort William College at Calcutta, was being formed, and was destined to give no less an impulse to the cultivation of Urdu prose than had a hundred years before been given to that of poetry by Wali. At the commencement of the present century Sir John Gilchrist was the head of this institution, and his efforts were directed towards getting together a body of literature suitable as text-books for the study of the Urdu language by the European officers of the administration. To his exertions we owe the elaboration of the vernacular as an official speech, and the possibility of substituting it for the previously current Persian as the language of the courts and the government. He gathered together at Calcutta the most eminent vernacular scholars of the time, and their works, due to his initiative, are still unsurpassed as specimens of elegant and serviceable prose composition, not only in Urdu, but also in Hindi. The chief authors of this school are Fardausi (Sayyid Muhammad Haidar-bekhab), Husamut (Mir Bahadur 'Ali), Mir Amman Lutf, Hafizuddin Ahmad, Sher 'Ali Afsoh, Nihal Chand of Lahore, Kásim 'Ali Jawán, Lalul Lal Kavi, Mazhar 'Ali Wili, and Ikram 'Ali.

Haidari died in 1828. He composed the *Tutá Fakárah* (1801), a prose reduction of the *Fari-námah* which has been already mentioned, a romance named *Ashah's Maghál* ("Ornament of the Assembly"), details of the adventures of the famous Arab chief Hikmat Tuti, the *Qud's Maghál* or *Dah Maghál*, an account of the holy persons of the Muhammadan faith, the *Qudat's Dáshah*, a translation of the *Behár's Dáshah*, a Persian work containing stories descriptive of the virtues and faithfulness of women, and the *Tutá Ali's Maghál*, a translation of a Farsián history of Nádir Shah. Husamut is the author of an imitation in prose of Mir Husein's *Shah-i-hayán*, under the name of *Nasir's Bazar*, a beautiful parable prose, and of the *Prose of Bazar*, the latter being the name of the hero, and of a work named *Ashah's Bazar*, or "Indian Morals," both composed in 1808. The *Ashah's Bazar* is an imitation of a Persian work called the *Ashtásh* ("the Delights of Reality"), itself a version of the *Itiháshah*. Mir Amman was a native of Delhi, which he left in the time of Ahmed Shah Durrani for Patna, and in 1801 repaired to Calcutta. To him we owe the *Diagh's Bazar* (1801-2), an adaptation of Amir Khusrau's famous Persian romance entitled the *Chahár Dáshah*, or "Story of the Four Dervishes." Amman's work is not itself directly modelled on the Persian, but is a reworking of an almost contemporary rendering by Tahsin of Esfah, called the *Nasir's Bazar*. The style of this composition is much admired by natives of India, and editions of it are very numerous. Amman also composed an imitation of Husein Wáiz Káshghi's *Shah-i-hayán* under the name of the *Shah's Káshghi* ("Treasure of Virtue"), reprinted in 1802. Hafizuddin Ahmad was a professor at the Fort William College, in 1808 he completed a translation of Abu Fawá's *Jayr's Dáshah*, under the name of the *Shah's Dáshah* ("Treasure of the Understanding"). The *Jayr's Dáshah* is a "Trench stone of Wisdom" is one of the numerous imitations of the

originally Sanskrit collection of apocryphs known in Persian as the *Tablas of Budaip*, or *Kutlah and Damash*. Afsoh was one of the most illustrious of the Fort William school, originally of Delhi, he left that city at the age of eleven, and entered the service of Asim 'Ali Khan, Nawab of Bengal, and afterwards repaired to Hindustan in the Dakkhin, and thence to Lakhnau, where he was the pupil of Mir Husein, Mir Sor, and Mir Haidar 'Ali Haidar. He joined the Fort William College in 1801, and died in 1808. He is the author of a much esteemed *divan*, but his afterwards reputation is founded on two prose works of great excellence, the *Diagh's Maghál* (1808), an account of India adapted from the introduction of the Persian *Ashah-námah* translated by Sir John Hall, and the *Diagh's Dáshah* (1808), a translation of Sa'ad's *Qudat's Dáshah*, translated into Urdu *amman*, entitled the *Qud's Dáshah*, under the name of *Ashah's Jayr* ("Religion of Love"), this work is in prose unimpaired with verse, was composed in 1804, and has been frequently reprinted. Jawri, like most of his collaborators, was originally of Delhi and afterwards of Lakhnau, he joined the College in 1800. He is the author of a version in Urdu of the wall-knowledge of Sa'ad, under the name of *Sa'ad's Dáshah*, the Urdu was rendered from a previous Bráj bháshá version by Nawab Kabirshah died in 1716, and was printed in 1802. He also composed a *Diagh's maghál*, or poetical description of the twelve months, a very popular and often handed form of composition, with accounts of the various Hindu and Muhammadan festivals, entitled the *Dáshah's Hind* ("Usages of India"), printed in 1812. Ikram 'Ali translated, under the name of the *Shah's ashtásh*, or "Brother's Joy" (1810), a chapter of a famous Arabian collection of treatises on science and philosophy entitled *Rashah's Dáshah's ashtásh*, and composed in the 10th century. The complete collection, due to different writers who dwell at Bagdad, is now recently made known to Europeans by the translation of Dr F. Dietrich (1858-1879), the chapter selected by Ikram 'Ali is the third, which succeeds in allegorical style for the mastery between men and animals before the king of the animals, and is an excellent Urdu, and is one of the best of the Fort William productions.

Sir Lalul Lal was a Brahman, whose family, originally of Gujrat, had long been settled in Northern India, and was one of the best of the other Fort William authors for Urdu prose was done by Lalul Lal almost alone for Hindi. His *Fari-námah*, and *Diagh's*, the former a version in prose Hindi of the 10th chapter of the *Shah's ashtásh*, and the latter a translation of the history of the famous Arab chief Hikmat Tuti, are two of his best works. He also composed a Bráj bháshá version by Chaturbhuj Mair, and the latter an adaptation in Bráj bháshá prose of the *Shah's ashtásh* and part of the *Farah's ashtásh*, are unquestionably the most important works in Urdu prose. The *Fari-námah* was begun in 1804 and ended in 1810, it enjoys immense popularity in Northern India, has been frequently reprinted in a lithographed form, and has several times been pirated. The *Diagh's* was composed in 1809, it is much admired for its sententious brevity and the purity of its language. Besides these two works, Lalul Lal was the author of a collection of a hundred anecdotes in Hindi and Urdu entitled *Lalul's Hind*, an anthology of Hindi verse called *Shah's Hind*, a *Sat* set in the style of Bihari Lal called *Sapta Satika*, and several other works. He and Jawán worked together at the *Singhán's Bazar* (1801), a reduction in mixed Urdu and Hindi (Devanagari character) of a famous collection of legends entitled the *Shah's ashtásh*, and he also aided the latter still in the production of the *Shah's ashtásh*. Mazhar 'Ali Wili was his collaborator in the *Shah's ashtásh*, a collection of stories in Urdu, and he aided Wili in the preparation of Urdu of the *Story of Maháman*, a romance originally composed in Bráj bháshá by Moti Ram.

The works of these authors have been compiled and published under the superintendence of Dr Gilchrist, Captain Abraham Lockett, Professor J. W. Taylor, Dr W. Hunter, and other European officers of the College, are essentially Indian in taste and style, and owe to this character a popularity and wide reputation which have been gained by no other work (and there have been many) undertaken under British initiative. If not absolutely the first works in Urdu and Hindi prose, they were at any rate the first works in these languages to be popularly read, and the whole of literary enterprise in these languages is due either to their influence or to one of two other impulses, the first of which was almost synchronous with the Fort William productions, and the other was a more recent one. These were the reform in jallá, led by Seyyid Ahmad, and the introduction of lithography and a newspaper press.

Seyyid Ahmad was born in 1783, and received his early education at Delhi, his instructors were two learned Muslims, and he was the author of a celebrated commentary on the *Qur'án* (the *Tafsi'r-i-Lamghani*), and his brother 'Abdu'l Qádir, the writer of the first and best translation of the Holy Volume into Urdu. Under their guidance Seyyid Ahmad was a devoted student of the Wahabite, a sect whose preaching appears at this time to have first reached India. He gathered round him a large number of fervent disciples, among others Izzat 'Ali, nephew of 'Abdu'l-Aziz and

greater number merely act as middle-men between the ultra-venturous and the large merchants. The municipal committee have opened a large gravelled market-place and storage-yard, with raised platforms, and scales for weighing the cotton. The place consists of Old and New Hinganghat,—the former, a straggling town, liable to be flooded by the river Wan', the latter, in which the better classes reside, laid out in broad streets and avenues.

HINOJOSA DEL DUQUE, a town of Spain, in the province of Cordova, from which city it is distant about 68 miles N by W. The manufacture of linens and woollens is carried on to some extent, the population is estimated at about 8500.

HINTON, JAMES (1822-1875), aural surgeon and author, son of John Howard Hinton, Baptist minister and author of the *History and Topography of the United States* and other works, was born at Reading in 1822. He was educated at his grandfather's school near Oxford, and at the Nonconformist school at Harpenden, and in 1838, on his father's removal to London, was apprenticed to a woollen draper in Whittochapel, where he came into contact with a phre of human life in its miserable and degraded forms which influenced powerfully the whole cast of his after thought. After retaining this situation about a year he became clerk in an insurance office. The most of his evenings were spent by him in intense study, and thus, joined to the ardour, amounting to morbidness, of his interest in mental problems, so affected his health that in his nineteenth year he resolved to seek refuge from his own thoughts by running away to sea. His intention having, however, been discovered, he was sent, on the advice of the physician who was consulted regarding his health, to St Bartholomew's Hospital to study for the medical profession. After receiving his diploma in 1847, he was for some time assistant surgeon at Newport, Essex, but the same year he went out to Sierra Leone to take medical charge of the free labourers on their voyage thence to Jamaica, after which his interest in their welfare prompted him to remain a year on the island. After his return to England in 1850, he entered into partnership with a surgeon in London, where he soon had his interest awakened specially in aural surgery, and gave also much of his attention to physiology and to problems bearing on the relation between mind and body. In his practice he became convinced that in the immense majority of cases of ill-health it was the hope of cure rather than the drug that effected the remedy, a fact which explained to him much of the success of homoeopathy, and induced him to lay the principal stress on moral methods of cure. He made his first appearance as an author in 1856 by contributing a series of papers on physiological and ethical subjects to the *Christian Spectator*, and the success of his work *Mind and its Dwelling Place*, which appeared in 1858, determined him, notwithstanding that he had married in 1852, to give up his medical practice in order to devote his whole attention to writing on those practical moral problems which chiefly occupied his thoughts. A series of papers entitled "Physiological Riddles," which he contributed to the *Cornhill Magazine*, and afterwards published under the title *Life in Nature*, as well as another series entitled *Thoughts on Health*, written for the same periodical and collected and published separately in 1871, gave evidence of great aptitude in popular scientific exposition, but his interest in speculation was too absorbing to permit him to apply himself with sufficient pertinacity to literary work, and after a year's trial of it he found it necessary to resume his profession. In 1863 he obtained the appointment of aural surgeon to Guy's Hospital, after which he speedily acquired a lucrative west end practice, and the reputation of being the most skilful aural surgeon of his day, a reputation fully borne

out by his works, *An Atlas of Diseases of the Membrana Tympani*, and *Questions of Aural Surgery*, which are regarded as the chief authorities in this branch of surgery. The skill he had now obtained in his profession seemed to justify him in 1869 in resuming his philosophical studies, but the mental excitement thus produced, added to his professional labours, appears to have inflicted permanent injury on his brain, and, although by giving up his practice in 1874 he obtained partial relief, he began to suffer from sleeplessness and depression, and died of acute inflammation of the brain, 16th December 1875.

In addition to the works already mentioned, Hinton was the author of the *Mystory of Man*, and *The Plagues of the Plagues*. On account of their fresh and vigorous discussion of many of the important moral and social problems of the time, his writings have had a wide circulation on both sides of the Atlantic. His contributions also several papers to the *Contemporary Review* and other periodicals. His *Life and Letters*, edited by Ellice Hopkins, with an introduction by Sir W. W. Gill, appeared in 1878.

HIIOGO, or Fuso, a seaport town of Japan, in the island of Nipon and province of Setzu, on the western shore of the Iddzumi Sea, or Bay of Osaka, about 40 miles S W of Kyoto, with which it has had railway communication since 1874. It was opened to foreign commerce in 1860, and since that date it has risen with the maritime suburb of Kobe (the Gate of God) to be a place of 50,000, or according to other authorities, 80,000 or 90,000 inhabitants. Its harbour, formerly dangerous, has by the construction of a costly breakwater been rendered one of the most serviceable in the kingdom. The best anchorage is found in front of Kobe, which has been chosen as the locale of the foreign settlement. Since the opening of the port great improvements have been effected in the native town, and the value of land and house property has greatly increased. The settlement, which consists of 189 lots, has been regularly laid out, its streets are macadamised and lighted with gas, and it possesses a bank, municipal buildings, and the largest warehouses yet erected by foreigners on Japanese soil. There is a recreation ground open to both natives and foreigners, with a cricket field and a croquet lawn. The population of the settlement was 169 in 1876, that of Kobe in 1874 was upwards of 8500. The trade of Hiogo consists mainly in the exportation of tea (1,599,199 dollars in 1877), silk, copper, camphor, wax, tobacco, ginseng, tangle, and dried fish, and the importation of European manufactured goods, including cotton, glass, &c. Most of the tea goes to New York, very little to London. The total value of the imports in 1874, 1875, 1876, and 1877 was respectively 6,080,239, 5,354,917, 3,748,967, and 4,813,641 dollars (the dollar being worth about 4s.), and the corresponding figures for the exports were 4,956,724, 3,813,103, 3,401,280, and 4,618,570. The industrial establishments comprise a shipbuilding yard, an iron-foundry, and a factory for the manufacture of paper pulp or "half stuff." There is a busy traffic maintained by ferry steamers between Hiogo and Osaka. The number of foreign ships that entered and cleared from the Port in 1875 was 335, with a burden of 453,958 tons. Hiogo was built in the days of the glory of the Tan family, and its name is equivalent to arsenal. At Minato Gawa near Kobe a small temple marks the spot where Kurohoki Messahige, the marquis of Japanese loyalty, met his death, and in Kobe itself there is a temple erected on the site of the ancient one built by Jingū Kōgo on his return from Corea.

HIPPARCHUS, the founder of mathematical astronomy, was born at Niseus in Bithynia. The years of his birth and death are both unknown, but the period of his activity, according to the evidence of his observations, which have been preserved by Ptolemy, must have been between 160 and 125 B.C. Of his writings only one has come down to us, *Τὸν Ἀράτου καὶ Ευδόξου φαινόμενα ἑξηγήσας*, *βιβλία γ'*, published by Vittorius at Florence, 1587, and by

HIPPOLYTUS, Sr., according to the Roman breviary, was one of St. Lawrence's converts, who, when summoned before the emperor Valerian on account of the practice of his religion, made a public profession of Christianity. First beaten with rods, he was finally delivered over along with all his family to death, the mode of execution in his case being similar to that by which Hippolytus the son of Theseus perished. The mythical character of this legend, which, however, even in part be traced as far back as to Prudentius (*Hymn*. 11), is recognized by Döllinger (see his *Hippolytus u. Kallistus*, chap. II). This saint, along with Cassianus, is commemorated by the Roman Church on August 13. He is the patron of Mexico.

HIPPONAX, of Ephesus, a poet placed third, after Archilochus and Simonides, among the classic iambic poets of Greece. Expelled from Ephesus in 540 B.C. by the tyrants Athenagoras and Comas, he took refuge in Clazomenae. There his deformed figure and malicious disposition exposed him to the caricature of the Chian sculptors Bupalus and Athenia; and he avenged himself by issuing against them a series of satires. These, though keen and bitter, are in thought and execution much inferior to the satirical works of his predecessor Archilochus. His coarseness of thought and feeling, his rude vocabulary, his want of grace and taste, and his numerous allusions to matters of merely local interest prevented his becoming a favourite in Attica. He invented epic parody, and the four opening lines of a parody on the *Iliad* have been preserved in Athenaeus (xv. 698 D). He was also the inventor of a peculiar metre, named after him by many writers, called the *sestos* or *choliambus*, which substitutes a spondee for the final iambus of an iambic senarius. His works, which were imitated by Herippus of Smyrna, were at an early date mingled and confused with those of Anaxilus, for whom some even claim the invention of the choliambus.

HIPPOPOTAMUS, a family (*Hippopotamidae*) of artiodactyls; ungulate mammals comprising two genera, each containing a single living species. Of these the best known is the hippopotamus (*Hippopotamus amphibius*), occurring

Hippopotamus.

only in Africa, where it abounds in many of the river courses. It is a huge unwieldy creature, measuring in the largest specimens fully 14 feet from the extremity of the upper lip to the tip of the tail, while it ordinarily attains a length of 12 feet, with a height of 5 feet at the shoulders, and a girth round the thickest part of the body almost equal to its length. Its remarkably small ears are exceedingly flexible, and are kept in constant motion when the animal is seeking to catch a distant sound. Its eyes are placed high up on the head, and but little below the level of the ears; its gape is wide, and its upper lip thick and

bulging so as to cover over even the largest of its teeth when the mouth is closed. It is provided with a considerable number of molar teeth adapted for grinding vegetable substances, and a formidable array of long spear-like incisors and curved chisel-edged canines or tusks which, according to Baker, root up the rank grass like an agricultural implement. Its legs are short, so that the body is but little elevated above the ground; and its feet, which are small in proportion to the size of the animal, terminate in four short toes each bearing a small hoof. With the exception of a few tufts of hair on the lips, on the sides of the head and neck, and at the extremity of the short robust tail, the skin of the hippopotamus, some portions of which are 2 inches in thickness, is entirely destitute of covering. It is usually of a dark fleshy red colour, irregularly marked with blackish spots. The hippopotamus is a gregarious animal, living in herds of from 30 to 40 individuals on the banks and in the beds of rivers, in the neighbourhood of which it most readily finds its appropriate food. This consists chiefly of grass and of aquatic plants, of which it consumes enormous quantities, the stomach of one of these creatures being capable of containing from 5 to 6 bushels. They feed principally by night, remaining in the water during the day, although in districts where they are little disturbed by man they are less exclusively aquatic. In such remote quarters they put their heads boldly out of the water to blow, but when rendered suspicious by man's persecution, they become exceedingly cautious in this respect, only exposing their nostrils above the water, and even this they prefer doing amid the shelter of water plants. In spite of their enormous size and uncouth form, they are expert swimmers and divers, and, as it is said, remain easily under the water from five to eight minutes. They are also said to walk with considerable rapidity on the bottoms of rivers, beneath at least a mass of water. At night, fall they come on land to feed; and when, as often happens on the banks of the Nile, they reach cultivated ground, they do immense damage to growing crops, destroying by their ponderous tread even more than they devour. To scare away those unwelcome visitors the natives in such districts are in the habit of kindling great fires at night. Although they do not willingly go far from the water on which their very existence depends, occasionally they have been found to travel long distances by night in search of food, and in spite of their clumsy appearance they are able, according to Baker, to climb up steep banks and precipitous ravines with astonishing power and ease. Of a wounded hippopotamus which that traveller once saw leaving the water and galloping inland, he says, "I never could have imagined that so unwieldy an animal could have exhibited such speed. No man could have had a chance of escape." The hippopotamus does not confuse itself to rivers only, but when opportunity occurs of exercising choice it has been known to prefer the waters of the ocean as its home during the day. Of a mild and inoffensive disposition, it seeks to avoid collision with man; when wounded, however, on the defence of its young, it is wont to exhibit the greatest ferocity, and the native canoes are frequently capized and occasionally demolished by its infuriated attacks, its usual bellowing grunt then becoming loud enough to be heard a mile away. As among elephants, so also among hippopotami there are "rogues"—old bulls which, having been expelled from the herd, have become sored in solitude; these are at all times dangerous. Assuming the offensive on every occasion, they attack all and sundry without shadow of provocation; the natives, therefore, are careful to avoid the haunts of these *solitaires*, which are usually well known.

The rifle of the European has proved the most potent destroyer of the hippopotamus; but to prove effective it

must be aimed at the head, the most vulnerable points in that region being immediately behind the ear and in the eye. Everywhere regarded as a valuable prize, the natives employ a variety of methods in order to secure it, the most common of these being the use of an iron harpoon attached to a line. Allowing themselves to float down stream on a raft, the hippopotamus hunters no sooner reach the sleeping herd than the expert of them plunges his harpoon deep into the body of the selected victim. The light canoes are then launched from the raft, and with all speed the hunters wade to the shore, bearing with them the line attached to the harpoon, which they further secure by fixing it a turn round the trunk of a tree. Unable to free itself, the hippopotamus wastes its strength in impotent rage, its persecutors meanwhile assailing it with a shower of javelins under which its life blood gradually ebbs away, until at last it is hauled up dead or dying on the shore. Another native method of destroying these animals is by means of a trap known as the "downfall," consisting of a heavy wooden beam armed at one end with a poisoned spear-head and suspended by the other to a forked pole or overhanging branch of a tree. The cord by which the beam is suspended descends to the path beneath, across which it lies in such a manner as to be set free the instant it is touched by the foot of the passing hippopotamus, the beam thus liberated immediately descends, and the poisoned weapon passes into the head or back of the luckless beast, whose death in the adjacent stream takes place soon after. Such "downfalls" are placed over the paths by which the animals are in the habit of reaching their nightly feeding grounds. They are also occasionally taken by means of ordinary pitfalls, so dexterously concealed as often to entrap the unwary traveller. Although inferior in sagacity to the elephant, the hippopotamus is very far from being stupid, as is frequently proved by its remarkable adroitness in the discovery and avoidance of traps and pitfalls, as well as in its timely migration from localities which, owing to the prevalence of the rifle, have become no longer tenable. It is said to be possessed of a remarkably tenacious memory, so that, according to Sir Andrew Smith, when once it has been assailed in its watery dwelling and injured through incautiously exposing itself, it will rarely be guilty of the same indiscretion a second time, even although a very long period should elapse before its haunts are revisited. The female is less in size than the male, and is exceedingly sly, taking to the water with her young, which she usually carries astride on her neck, on the slightest alarm. It is only after long practice that the young become able to remain so long under the water, and for this reason the females while tending them come much oftener to the surface than their own necessities require. The period of gestation, as observed in females confined in the Zoological Gardens of London and Paris, extends to nearly eight months, the young reach maturity in five years, and the full term of life in the species is believed to extend to thirty years. The male hippopotamus which recently (1878) died in the Zoological Gardens, London, was captured in August 1849 when

only a few days old, it had thus nearly attained the age of twenty-nine, while an examination of its dead body disclosed, says Professor Owen, "no special morbid appearance to suggest that death from old age had been anticipated" (*Annals and Magazine of Nat. Hist.*, September 1879). The flesh of the hippopotamus is generally considered a delicacy both by natives and colonists, although according to Livingstone there are certain tribes on the Zambesi who have as great an abhorrence of hippopotamus meat as Mahometans have of swine's flesh. The fatty matter lying between the skin and the muscles is one of the purest of animal fats, and was formerly in great request among the Cape colonists when as yet those amphibious abounded in the rivers of that colony. The skin of the hippopotamus is turned to profitable account in the manufacture of elastic whips, which are in great demand throughout the African continent. The skin, according to Schweinfuth, when fresh is cut into long quadrilateral stripes, which when half-dried are trimmed with a knife and afterwards hammered out, like iron on an anvil, into round whips. As several hundreds can be made from a single hide, that part is of considerable commercial value. Still more valuable are the tusks and incisor teeth, which, from their extreme hardness and the fact that they do not readily become yellow, are now largely used in the manufacture of artificial teeth. The hippopotamus formerly abounded in such rivers as the Nile, the Niger, the Senegal, and most of the rivers of South Africa. It is now, however, becoming gradually more restricted in its distribution, having disappeared altogether from the Egyptian Nile,—although still abundant in its Abyssinian tributaries,—as well as from the rivers of Cape Colony.

The Liberian hippopotamus (*Chacoopsis liberiensis*), the only other existing member of the family, is exceedingly rare, having been only known until recently from the two skulls on which the genus and species were founded. It differs from the common species in possessing only one pair of incisors in each jaw instead of two, and in several other minor points. A few years ago a young specimen of this rare species was brought alive to England from the Senegal river, north of Sierra Leone, but it died soon after landing. The species is found on the west coast of Africa and on certain of the rivers flowing into Lake Chad.

Although there are thus only two living species, both of which are confined to Africa, the hippopotamus family was both larger and more widely distributed in former periods of the earth's history, fossil remains of at least nine species having been found in the Tertiary deposits of Europe and the south of England, but they are found nowhere in such abundance as in the island of Sicily, from which they were formerly exported in shiploads to England and France, where they were used in the manufacture of lamp black and manure. The occurrence of these animals in a place which they could not possibly have reached had it always been an island, is regarded as one of the many proofs that dry land existed during some portion at least of the Tertiary period between Italy and Africa.
